In every case during the acute stage of the illness, the pneumococcus was isolated from the middle meatus of the nose. The pneumococcus invariably corresponded in type to that found in the sputum and in the blood. During convalescence, pneumococci could not be isolated from the middle fossae of the nose in those instances in which cultures were made.

In view of the regularity with which the pneumococcus was recovered from the nasal passages during the active stage of the disease, it seems likely that nasal culture may offer a method for the isolation and typing of the organism in the occasional case in which no sputum is obtainable.

COMMENT

Since Darling's communication in 1906 presenting his necropsy studies of the paranasal sinuses in lobar pneumonia and other pneumococcal infections, few data have been accumulated bearing on this subject. If Darling's surmise is substantiated that the portal of entry of the pneumococcus may be a paranasal sinus, the route by which the organism reaches the lung, whether bronchial, lymphatic or blood vascular, is not known. Sinus discharges might go directly down the bronchial tree, and the work of Blake and Cecil[5] shows that pneumonia can be produced by intratracheal injection of minute doses of pneumococci. The studies of

Table 2.—*Findings in Sixteen Cases of Lobar Pneumonia*

Case	History of Preceding "Cold"	Nasopharyngoscopic Examination	Roentgen-Ray Examination of Sinuses	Nasal Cultures: During Disease	Nasal Cultures: During Convalescence	Sputum Culture	Blood Culture	Lobe of Lung Involved	Comment
1	"Cold" several days; nasal discharge (right); frontal headache (right)	Moderate diffuse hyperemia; antrums clear on transillumination	Not made	Pneumococcus type I	Not made (death)	Pneumococcus type I	Pneumococcus type I (500 colonies per cc.)	Left upper Left lower Right middle	Patient died
2	"Cold" for 1 week	Marked diffuse hyperemia; mucoid discharge	Not made	Pneumococcus type I	No pneumococci	Pneumococcus type I	Negative	Left upper	
3	No note of "cold"	Diffuse hyperemia	Not made	Pneumococcus type IV	No pneumococci	Pneumococcus type IV	Pneumococcus type IV	Left upper	
4	Severe "cold" 2 weeks nasal discharge; frontal headache	Mild hyperemia; pus draining from both middle meatuses; antrums dark on transillumination	Clouding of antrums	Pneumococcus type I	No pneumococci	Pneumococcus type I	Pneumococcus type I	Right upper Right middle	Nasopharynx became normal during convalescence
5	No note of "cold"	Not examined during illness	Not made	Pneumococcus type I	No pneumococci	Pneumococcus type I	Negative	Right lower	Nasopharynx normal in convalescence
6	No note of "cold"	Hyperemia; crusted discharge; mucopurulent discharge in adenoid region	Clouding of right antrum	Pneumococcus type IV	Not made	Pneumococcus type IV	Negative	Left lower	
7	"Cold" several days	Purulent discharge from left side	Clouding of left antrum	Pneumococcus type IV	Not made	Pneumococcus type IV	Negative	Right middle Right lower	
8	"Cold" for 3 days	Marked diffuse hyperemia; mucopurulent discharge from middle meatus of both sides	Clouding of both antrums	Pneumococcus type I	No pneumococci	Pneumococcus type I	Negative	Right lower Left lower	
9	"Cold" for 10 days	Diffuse hyperemia; purulent discharge from left middle meatus	Not made	Pneumococcus type IV	No pneumococci	Pneumococcus type IV	Negative	Right lower Right middle	
10	"Cold" for 1 week nasal discharge	Slight diffuse hyperemia	Not made	Pneumococcus type II	Not made (death)	Pneumococcus type II	Pneumococcus type II (75 col. per cc.)	Right lower	Patient died
11	"Cold" for several days	General hyperemia	Clouding of both antrums	Pneumococcus type II (atypical)	Not made	Pneumococcus type II (atypical)	Negative	Right lower	
12	No "cold"	Diffuse hyperemia	Sinuses clear	Pneumococcus type I	Not made	Pneumococcus type I	Negative	Right upper Right lower	Nasopharyngoscopic and roentgen-ray examinations made 2 days after crisis
13	"Cold" for several days with headache	Marked general hyperemia	Not made	Pneumococcus type IV	Not made	Pneumococcus type IV	Pneumococcus type IV (2 col. per cc.)	Right upper Right lower	
14	No note of "cold"	Marked general hyperemia; mucoid discharge, especially on the left side	Clouding of left antrum	Pneumococcus type I	No pneumococci	Pneumococcus type I	Negative	Right lower	
15	"Cold" for 4 days	Slight diffuse hyperemia with mucoid discharge	Not made	Pneumococcus type IV	Not made	Pneumococcus type IV	Negative	Left lower	
16	No note of "cold"	Diffuse hyperemia; purulent discharge from both middle meatuses, especially the right	Clouding of antrums	Pneumococcus type IV	Not made	Pneumococcus type IV	Negative	Left lower

[5] Blake, F. G., and Cecil, R. L.: J. Exper. Med. **31**: 445 (April) 1920.

Mullen[6] indicate that in the rabbit, at least, lymphatic drainage of the maxillary and frontal sinuses is quite direct by way of the submaxillary and deep cervical nodes, to the cervical lymph ducts and the great veins. Carbon suspensions injected into the antrums could be traced along this course. Mullen's investigation was prompted by his observation of the frequent coincidence of sinus infection and bronchiectasis; indeed, he states that he has seen no cases of nonobstructive bronchiectasis without an accompanying sinusitis. It is a matter of common experience to observe the coincidental occurrence of acute sinusitis and bronchopneumonia, in which the history would indicate the sinusitis as the prior infection, and in which the sputum and nasal discharges contain the same offending organism. While no attempt is made to draw any analogies between the two types of pneumonia, the occurrence of acute sinusitis as an accompanying infection in both diseases is of interest and of possible significance.

It is quite impossible to determine from existing data whether the paranasal sinusitis, when present, precedes or develops, *pari passu,* with the lobar pneumonia. The possible rôle of acute pneumococcal infection of the sinuses in the pathogenesis of lobar pneumonia cannot be considered until its temporal relationship to the pneumonia is settled. Suggestive, perhaps, is the history elicited from a considerable percentage of patients of a "cold" preceding the onset of the pneumonia; though how many of these preliminary "colds" are actually cases of pneumococcal sinusitis is not known, since rhinitis is too common a malady to admit of such exhaustive study as a routine. Darling states that, in the cases he studied, the age of the sinus infection was appreciably greater than that of the lung or meningeal lesion, though he does not give his criteria for drawing such conclusions. Whatever may be the etiology of the antecedent "cold," as soon as attention is called to the patient by the acute symptoms of the pulmonary infection, one finds in a certain percentage of cases (a figure varying probably with the degree of care taken in studying the patient) definite clinical, roentgenologic and bacteriologic evidence of acute pneumococcal sinusitis. This extrapulmonic infection appears to occur sufficiently frequently to receive more than a casual consideration. Even if it plays, contrary to Darling's belief, no part in the primary disease process, the evidence indicates that it is a common and early complication of lobar pneumonia.

The series of cases here reported is too small to warrant the drawing of definite conclusions. The results are sufficiently striking, however, to encourage further investigation of this phase of the disease.

SUMMARY

1. In a series of sixteen cases of lobar pneumonia, pneumococci of corresponding type to those found in the sputum were isolated from the middle fossae of the nose in every case.
2. The nasal passages in fifteen of the sixteen cases were examined with the nasopharyngoscope; of these, all showed hyperemia of the mucous membranes, and six had signs of acute suppurative sinusitis. In eight cases, anteroposterior roentgenograms of the sinuses were made; in seven cases, clouding of one or more of the sinuses was observed.
3. In this small series of cases, acute pneumococcal sinusitis was a frequent accompaniment of lobar pneumonia.

PUERPERAL FEVER

II. STREPTOCOCCUS HEMOLYTICUS TOXIN AND ANTITOXIN *

ABRAHAM F. LASH, M.D.
AND
BERTHA KAPLAN, M.S.
CHICAGO

In June, 1925, we[1] reported the presence of a toxic substance in the Berkefeld V filtrate of broth cultures of *Streptococcus hemolyticus* isolated from the blood of patients with puerperal fever. Intracutaneous injections of the filtrates (sterile) produced inflammatory reactions, which varied in degree and incidence with the dilution of the filtrate and the presumable immunity of the patient. There was a definite latent period between injection and reaction.

The present report concerns experiments with the toxic substance in the filtrate, which were carried out in order to determine further characteristics of a toxin and the specificity of the organism. Strain A of our puerperal streptococci and the Berkefeld V filtrate of its cultures were used exclusively in the study.

HEAT LABILE PROPERTY

One cubic centimeter of the 1:100 dilution of the filtrate was heated in a water bath at 70 C. for fifteen minutes and a similar amount at 90 C. for sixty minutes. Intracutaneous tests were made on five pregnant women (at term) known to be strongly positive to the 1:1,000 dilution. In three, the tests were negative, while in one, it was slightly positive and in another positive. The positive reactions can be explained by a hypersusceptibility of the two patients to the proteins in the heated filtrate. The negative tests were due to the destruction of the toxic substance in the filtrate by heat.

NEUTRALIZATION

The immune serum was prepared in a rabbit by repeated intracutaneous injections of the undiluted filtrate. The initial dose was 5 cc., gradually increased until 13 cc. was given. Twenty-five injections were given at intervals of three days. A control serum was obtained from a nonimmunized rabbit. Equal amounts of the diluted filtrate (1:500 and 1:100) and of the immunized and nonimmunized serum were mixed and allowed to incubate for one hour at 37.5 C. Ten patients (pregnant women at term) who gave a positive test with the 1:1,000 dilution of the filtrate were inoculated intracutaneously with 0.2 cc. of the foregoing mixture. Thus, each patient received four injections, the 1:100 filtrate plus immune serum, 1:100 plus (nonimmune) control serum, and the 1:500 filtrate with similar combinations. In the control tests, strongly positive reactions occurred in twenty-four hours, while in those with the immune serum no reaction occurred except in one having a positive and in two only slightly positive reactions. Therefore the toxic substance in the filtrate was neutralized by the immune serum (antitoxin) with the stated exceptions, which were probably due to a very slight amount of toxin remaining active for hypersusceptible patients from incomplete neutralization by insufficient antitoxin.

[1] Lash, A. F., and Kaplan, Bertha: Puerperal Fever: Streptococcus Hemolyticus Toxin, J. A. M. A. 84: 1991-1992 (June 27) 1925.

PRECIPITIN TESTS

Equal amounts of the diluted serum and the centrifugalized, clear, supernatant fluid of forty-eight hour dextrose broth cultures were mixed and incubated at 37.5 C. dry heat for from twelve to fifteen hours, and readings were made after two and fifteen hours. The results are given in the accompanying table.

Results of Precipitin Tests

Strains of Streptococcus H	Serum of Rabbits Injected with— Toxin Intracutaneously	Toxin and Strept Hem Intracutaneously	Toxin Intravenously
Puerperal A	160	320	160
Puerperal A^1 *	80		...
Puerperal B	160	80	80
Puerperal C	0	40	80
Erysipelas 1	40	40	80
Erysipelas 2	80	.	..

* Puerperal A^1 after passage through a rabbit

Although the results of the precipitin tests demonstate a nonspecificity of the strains of *Streptococcus hemolyticus* isolated from puerperal fever, yet they indicate a relationship between these strains.

ACTIVE IMMUNIZATION

Two forty-eight hour blood-agar slants of the puerperal strain A suspended in sterile physiologic sodium chloride solution were found to be the lethal dose in a rabbit (800 Gm.) after intravenous injection, in twenty-four hours. Necropsy revealed no gross pathologic changes, but cultures of the heart blood and peritoneal fluid (normal amount) yielded hemolytic streptococci. A rabbit (800 Gm.) was immunized with the undiluted toxin produced by the organisms isolated from this rabbit. Four injections were given intravenously in 9 cc. doses at intervals of three days. One week after the last injection, two forty-eight hour blood-agar slants of the puerperal strain A were injected intravenously. The animal was not affected and, when killed one month later, no pathologic changes were found.

In a series of rabbits, the virulence of *Streptococcus hemolyticus* was studied. Two forty-eight hour blood-agar slants injected intravenously were found to be the lethal dose. Three cubic centimeters of the toxin killed rabbits in twenty-four hours when given intravenously. One half of a forty-eight hour blood-agar slant combined with 2 cc. of the toxin injected intracutaneously proved fatal to two rabbits (800 Gm.). However, there was a great variation in the amounts of the organisms and the toxin given separately or combined necessary to kill rabbits of the same size. Also in the female rabbit no specific or selective property of the puerperal *Streptococcus hemolyticus* was observed. The nonspecificity of *Streptococcus hemolyticus* in the chronic infection of the fallopian tubes and cervix was demonstrated in a recent study.[2]

CONCLUSION

The toxic substance in the sterile Berkefeld V filtrate of puerperal *Streptococcus hemolyticus* broth cultures is a toxin because:

1. There is a latent period between injection and reaction.
2. The toxic substance in the filtrate is heat labile.
3. It is neutralized by immune serum (antitoxin) and not by nonimmune serum.
4. The precipitin tests further show the development of immune bodies by the toxin.
5. The repeated injections of the toxin produced sufficient antitoxin to protect rabbits against the lethal dose of the puerperal *Streptococcus hemolyticus*.

LONG STANDING ANURIA

CERTAIN ASSOCIATED PHENOMENA

W. A. MYERS, M.D.
KANSAS CITY, MO.

Recently I[1] reported a case of anuria in which there was no evidence of urine having been passed for thirty days. Until this case was seen it had never been brought to my attention that a complete suppression of urine could possibly exist for more than five or ten days. Every day, therefore, not only the attendants at the bedside, but also the physicians in charge expected dissolution. I have since found other cases in the literature and included in the report a collection of those having a duration of from twenty to twenty-nine days, and some of even longer duration. However, I have been unable to find a report of a case due to recurrent carcinoma with such a history.

The patient was a woman, aged 64, who had had a polypoid type of cervical growth for years, which was finally removed with the uterus by vaginal hysterectomy. From a careful history of the case there was no reason to think that recurrence of the carcinoma ever attacked the vesical, vaginal or rectal wall, but both history and necropsy definitely pointed to the recurrence in the lymphatics and tissues on each side of the cervix; that is, around the ureters just before their entrance into the bladder. Pressure symptoms of a pelvic mass arose on the right side at least five months before the onset of anuria, and at necropsy both the mass and the hydronephrosis were larger on this side. The symptoms of intoxication, marked by frequent vomiting, began at least two months before anuria developed. Complete occlusion of the ureters, there is reason to believe, was very gradual, and occurred first on the right side, renal function being assumed partially by the remaining kidney, up to the time when the left kidney was likewise occluded, on or before Aug. 22, 1923, the date alleged as the beginning of complete anuria.

This interpretation coincides with the dictum of authorities,[2] which has generally been accepted, that longstanding obstructive anuria may occur only in those who have been living through the function of one kidney. Thus, the prerequisites for a longstanding obstructive anuria seem to have been fulfilled in this case. The gross appearance of the recurrent masses entirely compressing the ureters for several centimeters on each side seems ample evidence to justify this interpretation. As a rule, both the physiologist in his laboratory and the clinician at the bedside are in perfect accord that complete anuria of only a few days' duration is extremely perilous to life. There is definite variability, apparently, between the tolerance of different species of animals to renal intoxication; for, according to Amos,[3] guinea-pigs after unilateral ureteral obstruction lived, on an average, nineteen and one-half days, whereas rats, under the same conditions, lived, on an average, fifty-two days; but in each species when "both ureters were tied the animal died in two days." Caulk[4] says: "I have never seen an animal with both ureters simultaneously ligated which did not die within four or five days." By two stage double nephrectomy, however, Vitzou[5] claims that he has kept animals alive for as high as from 146 to 164 hours by no other measure than the injection of blood serum from renal veins of healthy animals of the same species. This he interprets as due to the internal secretion of the kidneys. Allen, Scharf and Lundin[6] report that whereas dogs die in two days with double nephrectomy, sheep and goats live for two weeks. Papin and Chabanier,[7] however, refer to clinical anuria, following nephrectomy of the only kidney in man (about ten cases) death occurring "about the tenth or twelfth day." I have collected from American literature records of three clinical cases, mentioned below, each patient having lived more than ten days after the removal of the only kidney.

[1] Myers, W. A.: Obstructive Anuria. Report of a Remarkable Case, J. A. M. A. 85:10-13 (July 4) 1925.

[2] Hutchinson, J.: Suppression of Urine as a Consequence of Renal Calculus, Lancet 2:1-3, 1874. Fowler, E. P.: Suppression of Urine, New York, William Wood & Co., 1881. Legueu, F.: De l'anurie calculeuse, Ann. d. mal. d. org. gen.-urin. 13:865-910, 1895.

The nearest approach we have clinically to the experimental conditions of bilateral ureteral obstruction are those cases collected by Bland,[8] sixty-one in all, in which both ureters were accidentally tied at operation. The anuria of these surgical cases was terminated as a rule within ninety-six hours, so that we have found no cases of long standing anuria among them. In the event of a surgeon accidently tying both ureters in patients presumably not suffering from renal intoxication, the shock of a difficult operation added to the anesthesia, and the instantaneous injection of all urinary toxins into the organism, consistently results fatally in a very few days unless at least one ureter is released mechanically. If, however, the patient is accustomed to renal poisons, at the time of operation, as in the cases in which diseased solitary kidneys have been removed, long standing anuria may result. Apart from the cases of long standing anuria, surgically produced, it is valuable to leave the laboratory and operating room, and search the literature for cases of anuria before surgery was generally utilized, or in present day cases in which its proffered hand of help, as in our own case, has been refused. Among the cases treated nonsurgically, we find reported those who suffered as a rule from very gradual renal intoxication. To one unfamiliar with the condition of long standing anuria, the records collected below may seem almost incredible. Yet many of the cases are reported with records quite exact, and observations apparently quite accurate. Furthermore, the authors are in many instances widely known, and are of accepted veracity.

In this communication I prefer to neglect the cases in the literature, which are numerous, with an anuria of less than ten days, and record the following collection, no doubt incomplete, of total anuria with a duration of from ten to nineteen days. A recent collection of cases in excess of nineteen days was given in my original report.[8a] In the present collection, there are cases representing "prerenal," "renal" and "postrenal" anuria. Of anuria cases apparently complete, I have found seven cases of ten days;[9] eight cases of eleven days;[10] eight cases of twelve days;[11] ten cases of thirteen days;[12] three cases of fourteen days;[13] five cases of fifteen days;[14] six cases of seventeen days;[15] two cases of eighteen days,[16] and two cases of nineteen days.[17] There are doubtless other cases reported or unreported but familiar to the reader, which I have failed to incorporate in this collection of fifty-one cases. The foregoing cases will at least illustrate the point that anuria in man is possible of being complete and of long duration, and apparently may be definitely longer in the clinic than in the experimental laboratory with present methods of study.

If these reports are accurate, we are led to search for some explanation for the tenacity of life in such a prolonged uremic poisoning. Such cases of chronic uremia may possibly be explained on one or more of the following derangements of physiologic processes:

1. In long standing anuria there may be a lowered metabolism.
2. In long standing anuria, natural protective forces develop a defense against the peril of deranged metabolism.
3. In long standing anuria, the nitrogenous products may be eliminated vicariously.

LOWERED METABOLISM IN TOTAL ANURIA

I have been unable to find in the literature a case of total long standing anuria with careful reports of basal metabolic rates. The clinical description of chronic uremia from total renal insufficiency of long duration is distinctive. Such authors as Sinkler[18] and Senator[19] indicate that, in the typical cases, a chronic uremia develops in man a condition approaching hibernation found in animals. Describing the metabolic processes of his case of "hysteric anuria," Charcot said, the vital "fires are covered with ashes." Catabolic processes apparently do not break down the nitrogen products or oxidize with even normal rapidity carbohydrates and fats. In the absence of exact quantitative metabolic studies, it seems fair to rely on the clinical triad of hypometabolism; namely, reading of pulse, temperature and respirations. In this type of chronic uremia, respirations may not be high, Fowler putting the average at about 18, but they may be as low as 15, 12, 8 or 6 per minute,[20] or even as low as 4 per minute.[1] In long standing cases uncomplicated by fever, the pulse is not commonly increased. Bradycardia may even prevail;[21] 70 or lower, even 40 has been reported.[19] If unassociated with infection, the temperature is rarely high and may be frequently normal or low,[21] 97.6 F., 92.8 F.[1] or 86 F.[19] My own case confirms the foregoing throughout, and the reduced metabolism seems a rational explanation of the interesting blood urea nitrogen studies in my case. At first blush, it would seem that anuria of many days would have accumulation of nitrogenous bodies in the blood, extremely high. Judging from the urea nitrogen studies in my case, however, this urea nitrogen increased only 30 per cent in the last fifteen days of anuria—from 130 to 169 mg. per hundred cubic centimeters of blood. Anuria of much shorter duration has been recorded at much higher figures of urea nitrogen retention in the blood, but such cases, it will be found, were types of relatively acute uremia compared to the case being discussed, and may possibly be explained on a basis of reduced vicarious elimination, to be discussed below. Not only are the pulse, respiration and temperature quite characteristically not increased, but the drowsiness reduces the bodily activity to the minimum. In the absence of exact basal metabolic rates, it would seem that certain cases of long standing anuria may, from a metabolic view, be likened to vegetative types.

PROTECTIVE FORCES IN TOTAL ANURIA

The study of lowered metabolism does not alone explain why one could survive for days without any urinary excretion. Many a patient has succumbed to uremia with much less urea nitrogen concentration in the blood stream than occurred in the cases reported. On the other hand, many cases of renal insufficiency with or without anuria, with much higher nitrogenous products in the blood, are reported. Scholl and Foulds[22] report a fatal case of relative anuria of thirteen days, with total anuria of eight days, in which the blood urea at one time was 527 mg. per hundred cubic centimeters. Mosenthal and Lewis[23] report a case of polycystic kidney in a business man with renal insufficiency without anuria, who was alleged to be quite comfortable with his routine business matters for a period in excess of a year in spite of a blood urea nitrogen around 118 mg. per hundred cubic centimeters. Sweet[24] has indicated that not all renal insufficiency cases are absolute suppression of urine cases—that the protective mechanism against renal poison is identical in the "specific" or absolute anuric cases and in the "essential" anuric cases, in which certain low specific gravity urine may be passed. The patients in each type are poisoned and, as he has indicated, may die suddenly or may live a number of days. Each type, amply proved clinically and experimentally, may have not only marked nitrogen retention but also acidosis of high grade, the latter evidenced by high inorganic phosphorus and low carbon dioxide combining power of the blood plasma. Peculiarly enough, also, evidence has accumulated both by experimental and by clinical study that renal insufficiency of high grade may be associated with neither hypertension nor edema. Marked sodium chloride retention probably does not occur, and vomiting commonly present in long standing anuria may regulate the blood chlorides, as it apparently does in cases in intestinal obstruction.[25]

It seems now quite certain that, with absolute renal insufficiency in man and animals, marked nitrogen retention and acidosis consistently results. Likewise, careful study of the literature on anuria indicates that a very slow urinary intoxication seems a prerequisite for long standing vital resistance to the cumulative chemical and physical changes in the blood and the tissues. Feeding food with high sodium chloride and nitrogen producing content apparently hastens death.

One of the protective forces against renal intoxication has been thought to be the internal secretion of the kidney. In most of the clinical cases of long standing anuria there is renal tissue with circulation intact, and it is conceivable that internal secretion of the kidney is a factor. However, certain notable cases in American literature militate against this theory, as in Polk's[26] case of anuria of eleven days, Farnsworth's[27] of twenty-three days, and Gordon's[28] of twenty-seven days it was shown by necropsy that the only kidney had been removed, in each case a pathologic one. This would rather lead one to think that bodily tissues, other than renal, by meeting the gradually increasing intoxication, had built up natural defenses to protect against any renal catastrophe, with its lethal processes.

In the case that I reported, the patient, according to the history, had been definitely intoxicated for weeks before anuria developed and was apparently definitely protected, as it were, against these processes before the crash of anuria developed. For such a biochemical battle, the organism must be forewarned in order to be forearmed. How shall we know of the mechanism of this defense until we know what is the lethal agent? Perhaps a true antitoxin is formed; it takes time for this type of protection to be established, either experimentally or clinically. Could we produce in the sheep or goat a chronic nephritis analogous to that found in man, subsequent total renal extirpation might presumably produce anuria identical in duration to that found clinically, and opportunity thus be created for study of these extremely important protective forces.

VICARIOUS ELIMINATION

A typical case of anuria, such as mine or many others recorded, may conceivably present a lowered metabolism; there may even have been gained a prolonged tolerance to the deranged metabolic processes that usually kill in a very few days, and yet not all cases of chronic total anuria may be explained without an additional factor. The literature of our fathers more than of today explained the life in prolonged anuria on the basis of "vicarious elimination." By this term many older clinicians held, and modern students have not disproved, the hypothesis that in these cases poisons were eliminated, and processes of adaptation were carried on, by other than renal organs.

In a certain percentage of reported cases of total anuria of long duration in which careful studies have been made, there is evidence of compensatory elimination by other organs, notably the skin, gastro-intestinal tract and the lungs. Perspiration in long standing anuria is noted very frequently; some patients sweat freely, others less. It is possible, according to von Noorden,[29] to excrete as high as 3 Gm. of nitrogen daily through the skin.

We cannot neglect the possibility of the lungs being a means of compensatory elimination of nitrogen. Certain writers speak of the "urinous," "ammoniacal" or "foul" odor to the breath. Roberts believes that such elimination does not occur. Certainly, no urinous or ammoniacal odor was noted in my case, though the breath was definitely foul.

Wolff[30] has produced hydramnion in pregnant rabbits by ligating both ureters, and it is his opinion that the amnionic sac and the renal pelvis of the hydronephrotic kidney act in identical function as reservoirs for vicarious nitrogenous elimination. Necropsy showed that our patient had 500 cc. of pleural fluid; this may have acted as a safety reservior for partial elimination of the toxic agents.

The gastro-intestinal tract, however, is probably the most frequent and efficient means of vicarious nitrogenous elimination in anuria. Vomiting may be one of nature's protective mechanisms in anuric uremia. Charcot's patient vomited daily, and his analysis, though made with rather unrefined methods, showed urea present in the vomitus, so that he taught that the stomach was one of the eliminating organs in cases of anuria. It has been asserted that the stomach may even assume the rôle of concentration of nonprotein nitrogen products of the blood. I have never been able to confirm this. However, Canti [29] in one case found the blood urea 300 mg. per hundred cubic centimeters but the vomitus 600 mg., and von Noorden [29] believes that the gastro-intestinal tract is able to eliminate as much as 8 Gm. of nitrogen daily.

The excretory function of the stomach may be an important factor in the control of renal acidosis, it having been shown that vomiting is at times associated with a tendency to alkalosis, and this tendency to combat renal acidosis may possibly be of extreme value in long standing anuria. Stomach excretions, like urinary excretions, are acid, and it is conceivable that vicarious elimination of acid bodies through excessive vomiting may avert a fatal renal acidosis.

Even the salivary glands may excrete a certain amount of nitrogen, profuse salivation being mentioned in certain cases of long standing anuria. Hench and Aldrich [31] have shown that excretion of urea nitrogen through saliva is in definite proportion to the concentration of the blood.

While vicarious elimination alone might maintain life in the face of overwhelming intoxication, it is obvious that unless fluids were given freely, or some organ of excretion actually concentrated, very definitely, dehydration would exceed the detoxication, and the toxic products would conceivably reach very high percentages. If, however, as has been asserted, the stomach may concentrate its elements, the nitrogenous bodies of the blood may not, of necessity, be markedly increased as the anuria persists. While certain cases in the literature are marked by excessive vomiting, others are reported with complete absence of such compensatory elimination through vomiting, perspiration, diarrhea or salivation even in prolonged anuria. My patient vomited daily during the period of anuria, and was alleged to have done so for weeks previously, and had at times during the observation spontaneous profuse sweats.

On the basis of von Noorden's data, given above, of the possibility of the skin and gastro-intestinal tract eliminating as much as 11 Gm. of nitrogen daily, the equivalent of approximately 23 Gm. of urea might thus be eliminated each twenty-four hours with renal function in absolute abeyance. This is of extreme interest in the study of the tenacity of life in long standing anuria.

COMMENT

How long is total anuria compatible with life? Certain authors believe that this may depend on a number of factors, among which are those mentioned above; namely, the lowered metabolism, gradual onset, and compensatory elimination. My patient had a cancer that was destroying life. Certain cases reported, in which there was no primary death-producing illness, but anuria of long standing, lead one to believe that the organism when given fair warning, and sufficiently gradual intoxication, may fortify itself against enormous poisoning. Scarpini [32] in the discussion of his case, in which there was alleged to have been a complete urinary suppression of several months' duration, apparently believes that metabolism compatible with life in total anuria may, under ideal conditions, be "carried on indefinitely."

Hypothetically, this may be possible. However, a much wiser working point of view for the therapeutist is that suppression of urine at any stage is dangerous; after five days it is liable to end fatally at any moment, and a duration of ten days or more is extremely rare. Even after this, however, life may not be despaired of, as Minningham [33] reports a clinical case of total anuria of twenty-three days in which the patient lived and resumed renal function after nephrotomy.

CARBON MONOXIDE POISONING

GRADUAL, CUMULATIVE EFFECTS IN YOUNG CHILDREN, WITH REPORT OF A FATAL CASE *

A. M. STEVENS, M.D.
NEW YORK

Cold weather and the dark days of winter mean for our city population an increasing use of illuminating gas for warmth and light. Frequently, gas heaters and flexible gas tubing are bought at second hand without regard to leaks or imperfections. Such heat as the house affords is precious: the windows, which may have been kept open in early fall, are closed the greater part of the time night and day.

This is the situation that makes for a seasonal increase in the risk of carbon monoxide poisoning, acute and chronic, for persons of all ages, aside from the year-round liability of adults whose occupations have to do with furnaces, coal mining, gas manufacture or garage exhaust. At any time in the year an ordinary gas jet for illumination may be found to be leaking: in winter, with closed windows, it may easily become a menace to life.

In city houses there is a certain hazard in the incomplete combustion of coal in stoves, but the chief danger lies in the escape of illuminating gas. This, in the form of "water gas," contains about 30 per cent of carbon monoxide. When breathed even in small quantities in the presence of oxygen, carbon monoxide will combine with the hemoglobin of the blood corpuscles to form a relatively stable compound. This is due to the greater affinity of carbon monoxide for hemoglobin, which is considered to be from 220 [1] to 250 [2] times as great as oxygen.

[2] Henderson, Yandell: Carbon Monoxide Poisoning, J. A. M. A. **67**: 580 (Aug. 19) 1916.

Exposure to large amounts of the gas results in rapid displacement of oxyhemoglobin, which is easily dissociated, and a saturation of the blood with carbon monoxide. By the failure of oxygenation of the body cells there ensues a tissue asphyxia, especially of the brain, which results in unconsciousness and finally in death.

If a victim of gas poisoning is brought into the open air while yet alive, the carbon monoxide hemoglobin is only very slowly dissociated: for several hours blood cells of a characteristic cherry red may circulate uselessly with their load of carbon monoxide. Inhalations of oxygen with 5 per cent carbon dioxide will assist the dissociation.[3] Some have believed that besides the asphyxia there may be a direct toxic action of carbon monoxide on the body.[4] This view is disproved by the experimental work of Haldane.[5] It is probable that illuminating gas owes part of its toxicity to other constituents;[3] this added factor is a more powerful respiratory stimulus than pure carbon monoxide.

The acute cases of gas poisoning are dramatic and obvious. More difficult of detection is the gradual and insidious type of poisoning, which results from the continuous or repeated exposure to a small quantity of carbon monoxide. A certain amount of the hemoglobin is fixed by the gas inhaled and, before this is dissociated, a further exposure raises the level of carbon monoxide hemoglobin in the blood. According to Gettler,[6] adults may accumulate up to 5 per cent of carbon monoxide in the blood without symptoms. Glaister[7] remarks: "It must not be forgotten that carbon monoxide poisoning, owing to its cumulative action, may occur even in the open air." Henderson and Haggard[8] have summed up the cumulative effect of breathing small amounts of gas over a period of time:

> When the time is measured in hours and the concentration of carbon monoxide is expressed in parts per 10,000 of air, the physiologic effects may be defined by the equations:
>
> Time × concentration = 3, no perceptible effect.
> Time × concentration = 6, just perceptible effect.
> Time × concentration = 9, headache and nausea.
> Time × concentration = 15, dangerous.
>
> The meaning of this rule is that . . . breathing of air containing one part of carbon monoxide for four hours by a person sitting at rest and breathing quietly produces essentially the same effect as breathing air containing four parts for one hour.

It is important that this should be clearly understood because of an unfortunate paragraph in Peterson, Haines and Webster's Legal Medicine and Toxicology,[9] in which it is stated that "carbon monoxide is not a cumulative poison, but when inhaled in very small quantities it disappears from the blood. In cases of chronic gas poisoning the blood does not serve for diagnosis." The first sentence calls for revision. The second is no longer valid, since estimation of carbon monoxide by the method of Van Slyke[10] gives accurate values down to 1 per cent, while symptoms of chroni poisoning are probably not encountered until the con centration of carbon monoxide is above 5 per cent the blood.

In adults the symptoms of gradual or chronic ga poisoning are, first of all, *fatigue and muscular* weak ness; then headache, dulness, mental depression, poo memory, restricted fields of vision, ashy pallor, palp tation and irregularity of the heart; and, finally, nausea, vomiting, vertigo, slowing of the pulse, dyspnea, dilatation of the veins of the neck, polycythemia, and increasing torpor.[11]

It is interesting to note how many of these symptoms are subjective; that is, one must depend on the patient's story rather than on what is found on physical examination. The objective signs are suggestive only in the late phases when the amount of carbon monoxide in the blood is so great as to approach the stage of acute poisoning.

With children, the problem of gradual gas poisoning is more serious, and the younger the child the greater the danger and the more difficult it is to make a diagnosis. Older children, of school age, from whom a history of subjective symptoms might be obtained by careful questioning, are probably saved from the cumulative effect of escaping gas in an ill ventilated house by the very fact of their attendance at school and their hours of play in the streets. Younger children, and especially infants, have a peculiar susceptibility to the poisonous effects of carbon monoxide. This susceptibility varies directly with the respiratory exchange and the metabolic rate, and inversely as the weight of the body.[12] Boehm[13] says: "It is quite certain that children succumb rapidly to the action of the poison." According to Lancereaux,[14] "of those poisoned by carbon monoxide, those who have most need of oxygen, that is to say, the young, succumb most quickly or are most easily affected."

Subjective symptoms are out of the question in children under 4 years of age, and without a definite history of gas exposure the clinician has, as yet, no recognized symptom complex to lead him to a diagnosis in cases of gradual gas poisoning.

The following case seemed to be of sufficient interest to report in detail:

REPORT OF CASE

A. M., a boy, aged 7 weeks, was brought to the outpatient department of Bellevue Hospital, Oct. 22, 1925, with a complaint of vomiting.

The family history was negative. There had been four previous pregnancies, the children all living and well. This baby had been born in normal labor at term, and weighed 9 pounds (4 Kg.) at birth: it had been bottle fed from the first. There had always been a tendency to vomit, with failure to gain; the baby had been wakeful and cried bitterly. When he was about 6 weeks old, the mother noticed that the child cried very little and during the following week seemed dull, slept a great deal, took only a part of the feedings, and vomited after each bottle. Two days before admission, the baby seemed cold to the touch and all feedings were forcibly vomited. The bowels were constipated, but the stools were of the usual yellow when obtained by enema.

This history seemed to suggest pyloric stenosis.

When examined, the baby did not appear, at first glance, to be in a serious condition. There was no unconsciousness:

The limbs and head were moved about, and the pupils, in middilatation, reacted, though slowly, to light. At intervals the baby gave a short, rather feeble cry. There was obvious undernourishment, with a weight of only 6 pounds 3 ounces (2.7 Kg.); but the uniform pink flush of body and limbs gave a false impression of health. If anything, the hands and feet and lips were more brightly pink than the rest of the body.

On palpation, it was shocking to find the baby's flesh as cold as a corpse. External warmth was applied at once and the temperature taken. Not one of three clinical thermometers would register in the rectum as high as 94. In all, the mercury hung at least a quarter of an inch below that mark. A hot coffee enema was given, and the rest of the examination was carried out with the baby lying on warm water bags and blankets.

The skin was inelastic and showed dehydration. The respirations were irregular, slow and shallow. The breath was without odor. The pulse was not palpable at the wrist. The heart was slow and irregular, varying between 80 and 48 per minute. The spleen was not palpable. The reflexes were all very sluggish. There were no paralyses.

In cases of such extreme circulatory failure, one would expect to find a general pallor, with cyanosis of the hands and feet. The extraordinary bright pink flush led to the tentative diagnosis of carbon monoxide poisoning, and the mother was carefully questioned as to possible exposure. She denied any knowledge of escaping gas in the house: no gas heater had been in use; she was sure the family would have smelled gas if there had been a leak.

Meanwhile, Dr. Lester Rosenberg had done the rapid qualitative test for carbon monoxide. Three drops of blood from the baby's heel were allowed to drop into 5 cc. of water and shaken to a uniform pink solution. Three drops of control blood from his own finger were shaken with the same amount of water in a second test tube: to the contents of both tubes a drop of 5 per cent sodium hydroxide solution was added. The solution of blood from the baby remained a clear pink, while the control solution turned a dirty green. This showed the presence of carbon monoxide in the baby's blood of at least 10 per cent. Blood was then drawn for the quantitative test by the method of Van Slyke, as modified by Parker and O'Brien. Dr. A. O. Gettler reported a concentration of 18 per cent carbon monoxide.

The baby lived forty-four hours in the hospital, with a temperature always below 96 in spite of external heat. The pulse did not rise above 80 and was always irregular. The respirations became very slow and shallow down to 6 per minute.

Hypodermoclysis was given of 200 cc. of 5 per cent glucose, and repeated with 125 cc. of the same solution.

Oxygen was administered without apparent effect. Transfusion was attempted, but by the time a donor was obtained the baby was too far gone. During the first twelve hours about half of the milk mixture was taken and vomiting occurred only twice.

Examination of the blood revealed: hemoglobin, 80 per cent; red blood cells, 4,360,000; leukocytes, 18,000; polymorphonuclears, 88 per cent; lymphocytes, 10 per cent, and large mononuclears, 2 per cent.

The coagulation time was normal, and the bleeding time somewhat retarded.

The urine showed no acetone and was normal, except for a faint trace of albumin.

After death blood was again drawn for a quantitative test, and 8.5 per cent carbon monoxide was found.

A necropsy was done by Dr. B. M. Vance of the chief medical examiner's office, and an unobstructed pylorus was found. The only positive findings were fine reddish hemorrhagic spots throughout the lungs, and a congested condition of the spleen, liver and kidneys. Microscopic sections of the lung showed the small pathologic areas to be simply groups of alveoli filled with red blood cells; there was no surrounding inflammation. Sections of the brain, basal ganglions and medulla showed no pathologic change. Death was pronounced as due to carbon monoxide poisoning.

A visit of inspection to the house revealed a leak of illuminating gas from a central fixture in the front room of the flat. It was in this room that the baby's crib was placed at night. The apartment was of only three rooms, in which lived a family of seven, the mother and father and four children of 7, 6, 5, and 1½ years, respectively, besides the baby that had succumbed. There were only two outside windows, both in the front room: these were open "most of the time." The cook-stove, burning anthracite and in use only for preparing the meals, was in the middle room. Opening out of this was a dark room in which the baby had been kept in the day: a small window opening on the hall of the tenement had been kept open "part of the time."

The mother protested that the baby, for the past month, had been taken out nearly every day for two hours at least. The father, who was away all day, the older children, who were out of the apartment most of the time, and the 18 months old child, who played on the roof, all seemed well and gave no history of suggestive symptoms. The mother, who had been with the baby constantly, had suffered for the past five months from headache, always worse on waking in the morning. These headaches stopped after the gas had been shut off.

This is the sum of all the evidence obtainable, and it is only fair to say that the complete good faith of the mother is not to be questioned.

In the light of these facts is it possible to reconstruct the case with a fair degree of probability? It is not known how long the gas had been escaping into the apartment, but the amount at any one time must have been so small that no one noticed the odor. Accordingly, we must assume a gradual cumulative absorption of carbon monoxide, perhaps since birth. Before the concentration in the blood became at all high, we find the symptoms of vomiting, failure to gain, restlessness and constant crying. The last week of torpor, lost appetite, and forcible vomiting, with the final few days of lowered bodily temperature, slowed pulse and respiration, will represent the phase in which the carbon monoxide in the blood had accumulated to such a point as to impair the processes of oxidation in the body and to cripple the circulatory mechanism.

Lancereaux [14] quotes Cadet de Gassicourt as reporting a similar case, but with no reference to vomiting as a symptom. The infant, 29 days old, fell ill, refused to nurse, and slept constantly with eyes half closed. The pulse was feeble, respiration was slowed, and the temperature was normal or somewhat low, so that the baby was in almost a lifeless condition. All the symptoms were due to inhalation of small quantities of carbon monoxide from a badly burning stove. This patient recovered.

To illustrate symptoms in older children from repeated exposure to carbon monoxide, Koren [15] gives an account of three sisters, aged 4, 8 and 12 years, poisoned by carbon monoxide from a slow combustion stove. The air of the room was found to contain 0.4 per cent of carbon monoxide. The symptoms were slight jaundice with attacks of vomiting, general pallor of the skin, headache, breathlessness and dilatation of the veins of the neck. There were hemic murmurs of the heart, with enlargement of the spleen. The number of red blood cells and the hemoglobin percentages were much diminished. Albumin was present in the urine. The 8 year old girl died on the ninth day. At necropsy, marked cardiac dilatation was found, with advanced degeneration of the cardiac muscle. The other two children made a rapid and complete recovery.

---

[15] Koren, A.: Tre Tilfaelde af akut forløbende perniciøs Anaemi inden samme Husstand, Norsk. Mag. f. Lægevidensk. 6: 550, 1891.

Wilmer[11] reports a very interesting case of the effects of gradual poisoning by carbon monoxide on a family including several children, one as young as 4 years. Symptoms noted were listlessness, progressive pallor, loss of appetite, fatigue, night terrors, auditory disturbances and contraction of the visual fields.

It is reasonable to suppose that cases like these are not exceptional; that in every large city a certain number of gradual poisonings by carbon monoxide occur, but that very few are recognized as such. Since the danger is especially grave for infants, the mothers should be specifically warned in the use of gas appliances, and more than ordinary emphasis should be placed on the necessity of fresh air outings and ventilation in the home.

In the milder grades of gradual gas poisoning, the diagnosis will not be easy. When an infant is seen with torpor, subnormal temperature and a history of vomiting and failure to gain, it is only fair to question the mother as to the use of gas in the home and the amount of fresh air the baby has been getting. Certainly in such cases the simple and rapid qualitative test for carbon monoxide in the blood should be done before the usual diagnosis of malnutrition with gastroenteritis is allowed to stand.

The advanced cases are more easily recognized; in these the heart is slowed, the body temperature is very low, and the characteristic pink flush of the skin and mucous membranes serves as an index of the degree of saturation of the blood with carbon monoxide.

SUMMARY

1. There is a seasonal increase, in the winter, of the hazard of gas poisoning, acute and chronic.
2. There is a cumulative poisonous effect of repeated or continuous exposure to small amounts of carbon monoxide.
3. Young children and infants are peculiarly susceptible to gradual carbon monoxide poisoning.
4. In serious cases of gradual gas poisoning, there will probably be more than 10 per cent of carbon monoxide in the blood.
5. There is a simple and rapid qualitative test for carbon monoxide in the blood, which will show the presence of 10 per cent or more.
6. Clinicians should be on the alert to recognize cases of gradual poisoning by carbon monoxide, especially in infants.

55 East Seventy-Sixth Street.

Progression of Greek Education.—As regards the exercises which the Greeks after centuries of experience adopted in their system of physical training, we know most about those which were used at the great games. Probably the oldest of all is running, perhaps because the warrior required efficiency in this respect both for attack and for defense; the Greeks practiced endurance in a long race and making a short distance in the quickest possible time. Later came jumping, discus throwing, spear throwing and wrestling. These five exercises together made up the famous pentathlon, which was the most important event in the Olympic games. Those who could be victorious in all these five exercises must have attained very all round physical development. Running and jumping brought the legs into use, discus and spear throwing the arms, while wrestling gave strength to the torso. We learn from Aristotle that those who took part in the pentathlon were the most beautiful of human beings, and that their bodies were equally well developed as regards strength, ease and quickness.—Knudsen: A Textbook of Gymnastics, p. 2.

A SYSTEM FOR AN INTENSIVE POLLEN SURVEY

WITH A REPORT OF RESULTS IN CHICAGO *

KARL K. KOESSLER, M.D.
AND
O. C. DURHAM
CHICAGO

The necessity of reliable local botanic data in solving the hay-fever problem has been frequently emphasized, and a number of field surveys have been made in which the common weeds that produce wind-borne pollen were observed and listed. At least one observer (Scheppegrell) has reported careful studies of atmospheric pollen over long periods. While field observation gives exact information as to the seasonal and geographic factors, it does not yield very satisfactory quantitative data. Exposing oil-coated plates to catch the air-borne pollens and making differential counts of them at regular intervals is a method that gives very valuable quantitative results, but it should be supported

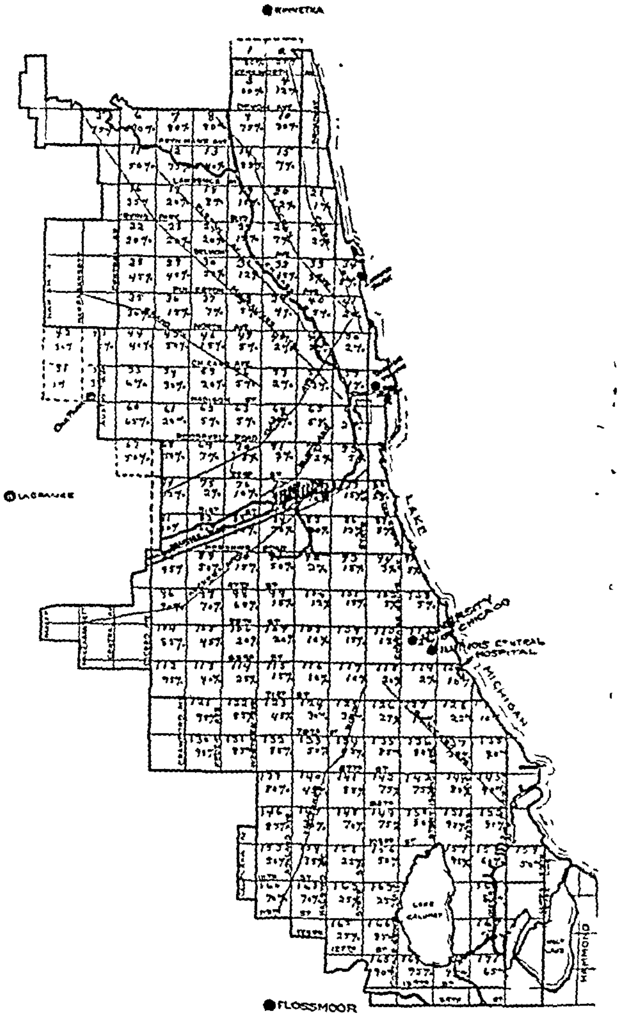

Fig 1.—Map used in field survey: The numbers on the squares correspond to those on cards in the index; plate stations are shown by the large dots. Each block is a mile square. Numbers correspond to those on cards in index where the pollen-producing plants are listed. Percentages indicate amount of area given to free vegetation.

---

* From the Otho S. A. Sprague Memorial Institute and the Department of Pathology, University of Chicago.

by careful field work. By using a combination of these two methods, we have been able to secure a large amount of satisfactory data on the distribution and abundance of the flora in Chicago; the time, duration and intensity of pollen production, and the relative importance of the offending plants.

METHODS

With the aid of a competent botanist in the field continuously from the first of June until the last of September, 1925, we were able to carry on a combined field and air survey of Chicago. The field work consisted in a city-wide examination of the hay-fever producing flora. For this purpose, the city was divided into 171 mile-square blocks (fig. 1), each of which was carefully inspected at least once during the season. A card index record (fig. 2) was made of each square, showing the percentage of its area given to free vegetation, the character of the area, and a list of all the important plants ranking in the order of their abundance in the square. Specimens of all plants studied were collected while in bloom and preserved as a permanent herbarium.

For the air study, stations were established in various parts of the city where oil-coated microscopic slides were exposed, from which, as far as weather conditions would permit, differential pollen counts were made daily. Corn oil or cottonseed oil was found to be better than glycerin for this purpose, because of the fact that they do not absorb moisture and thus distort the pollen grains. Stains were not found necessary in preparing the slides for counting. Distinctions between pollens of the various groups and species were based largely on the shape and surface markings. There is such variation in a single pure specimen that except where there is considerable normal difference between species, size was found not to be a safe point of distinction. Except in the case of corn, it was not found practical to distinguish between the various grasses. Short and giant ragweed pollens could not be differentiated, their average size (about 15 microns) and general appearance being very nearly the same. Hop and hemp could not be differentiated. The docks and plantains, though not related botanically, were also counted together.

FIELD STUDIES [1]

Chicago has no extreme differences of topography or soil; consequently, we find a striking similarity in the flora of all parts of the city. There is a little marsh land, near Lake Calumet, and almost no woodland. The suburban districts are either unbroken prairie or gardens. On account of numerous railways, widely scattered factory districts and the many detatched residential developments, there are large areas of neglected land comparatively near the center of the city. Only a few of our 171 squares are so closely built as to exclude vacant lots. Dense growths of ragweeds, sometimes 6 feet high, follow the banks of canals and rivers along most of their entire length. Within two and a half miles of the "Loop" can be found extensive weed patches. Even if weed cutting laws were enforced they would accomplish little, for most noxious weeds will make a second or even a third growth and will bloom almost in spite of anything. While grasses predominate in the undisturbed soil of the suburban districts, and the vacant lots closer in are more weedy, yet we found that the variety and amount of pollen were practically the same on a given day at the top of the Tribune Tower as they were near the ground in the Oak Park district. Thus, the plates confirmed the field observations as to evenness of distribution of species.

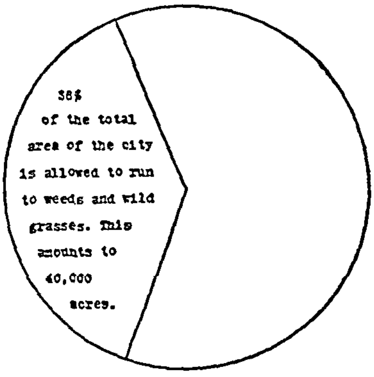

Fig. 3.—Weed area in Chicago: average of the waste area in the 171 squares into which the city was divided in making the survey.

The total of all neglected land in Chicago amounts to 38 per cent of the city's area (fig. 3). Thus, each year there are at least 40,000 acres within the city limits producing nature's own selection of weeds. An idea of what this means is gained by computing the amount of pollen an acre of ragweed will yield. An average city lot (about one-tenth acre) of ragweeds will produce a minimum of 100 ounces of pollen in a season. This is about 60 pounds per acre. Actual production is often many times this figure. This means that hundreds of tons of ragweed pollen alone are liberated each season in Chicago.

Table 1 is a list by groups of the plants studied. Trees were not included in the survey, as their pollinating season was past when the work was started. It is important to be familiar with these botanic groups and in the study of specificity of pollen reactions to remember a plant's family ties. All close relatives of offending species were closely watched. The botanic names are included in this list for reference, as the common name used for any plant in this article is at best a local one and likely to be only one of a dozen by which it is known throughout the country.

PRODUCTION FACTORS

To appreciate best the data embodied in the graphs and charts of totals and averages to be presented in the latter part of this paper, it should be noted that the three outstanding factors determining a plant's importance are length of season of bloom, abundance of plants and intensity of pollen production. As weather has less immediate effect on production of pollen than its distribution, its influence had best be considered in interpreting the totals.

---

[1] The field work and microscopic identification of plants was carried out under our direction by Mr. James H. Palmer and Mr. E. H. Runyon.

Tabe 1.—*Plants Studied*

Common Name	Botanic Name
Grasses	Gramineae
Timothy	Phleum pratense
Orchard grass	Dactylis glomerata
Corn	Zea mays
Bluegrass	Poa pratensis
Redtop	Agrostis palustris
Wild rye	Elymus spp.
Annual bluegrass	Poa annua
Wire-grass	Poa compressa
Quack grass	Agropyron repens
Ray grass	Lolium perenne
Fescue	Festuca spp.
Panic grass	Panicum spp.
Marsh grass	Spartina cynosuroides
Ragweeds	Ambrosiaceae
Short ragweed	Ambrosia elatior
Giant ragweed	Ambrosia trifida
Western ragweed	Ambrosia psilostachya
Burweed marsh elder	Iva xanthifolia
Cocklebur	Xanthium commune
Chenopods	Chenopodiaceae
Lamb's quarter	Chenopodium album
Oak-leaved goosefoot	Chenopodium glaucum
Maple-leaved goosefoot	Chenopodium hybridum
Russian Thistle	Salsola kali
Orache	Atriplex patula
Amaranths	Amaranthaceae
Pigweed	Amaranthus retroflexus
Western water hemp	Acnida tamariscina
Wormwoods	Artemisia
Mugwort	Artemisia caudata
Biennial sage	Artemisia biennis
Prairie sage	Artemisia ludoviciana
Composites	Compositae
Sunflower	Helianthus annuus
Tickseed sunflower	Bidens spp.
Goldenrod	Solidago spp.
Docks	Rumex
Yellow dock	Rumex crispus
Red sorrel	Rumex acetosella
Plantains	Plantago
Plantain	Plantago major
English plantain	Plantago lanceolata
Miscellaneous	
Hemp	Cannabis sativa
Japanese hop	Humulus japonica
Sweet clover	Melilotus alba
Tumbling mustard	Sisymbrium altissimum
Cat-tail	Typha spp.

The simplest of the foregoing factors is the time and length of the blooming season (table 2). Some species will bloom for an average of eight weeks, with the apex of pollen production near the middle of that time. The time of really effective production is as short as two days for some species and as long as a month for others. Annual bluegrass, sweet clover and lamb's quarter have unusually long seasons, while those of the wormwoods (mugwort, annual sage and biennial sage) are very short. Docks and plantains are the only weeds blooming during the grass season. The chenopods and amaranths bridge the gap between the spring and fall pollen seasons. While the dates given here will vary somewhat from year to year, the variation, particularly in late summer and fall, will not exceed two or three days. A study of the calendar alone might suggest that there are times when there are as many as twenty species of pollen in the air at once, but plate counts show that less than half that many are of consequence at any time.

* In the table, each sign, minus or plus, represents one week. The portion of the line denoted by ++++ represents the season of maximum observed pollination.

The relative abundance of plants in the field, as shown in table 3, was determined by the order of the appearance of the species in the card index. We find that the ragweeds, including marsh elder and cocklebur, equal in quantity all other free vegetation in the city. Grasses are about half as abundant. The next group in order is the amaranth, followed by the composites and chenopods. The rank of each species is as valuable as that of the groups. These figures are not subject to much variation on account of weather or season.

* The rôle played by sweet clover as a hay-fever plant is very problematic, but it seemed best to include it at this time in the table.

The important factor in intensity of production of pollen of each species is quite difficult to reduce to figures. Table 4 is the result of ten years of observation and experience in collecting pollen in quantities and is, of course, only approximate. This factor varies with the weather more than either of the other two. Giant ragweed is easily the heaviest pollen producer encountered in Chicago, though the highest plate count for any single species during the survey was for burweed marsh elder. Lamb's quarter yields heavily only under very favorable conditions, usually late in the fall. During the summer, it does not rank nearly as high as here given. Water hemp would enter more into the totals if it had a wider distribution. While it is the most common weed in one square (no. 92), it is not found at all in most parts of the city, being the extreme example in Chicago of a locally abundant plant. Mugwort could easily be a cause of trouble if it were more abundant.

TABLE 4.—*Relative Ability to Produce Pollen (Scale of 100)*

Quack grass	10
Sweet clover	3
Goldenrod	8

Orchard grass leads the grasses in pollen producing ability if not in acreage. The few examples given above illustrate the complexity of the pollen problem, when considered from any angle except that of the air analysis.

EVALUATION OF SPECIES

With the foregoing more or less artificial data in mind to help in interpreting our findings, it is profitable to study the actual performance of the same species and groups as shown by the air survey. The plate counts for all stations have been averaged for each day and condensed into one table (table 5). From this table several graphs have been drawn, one of the most interesting of which is the total graph (fig. 4). Two thirds of the pollen found on the slides was from the ragweeds, one fifth from the grasses; and of the remainder, the chenopods were the largest contributors.

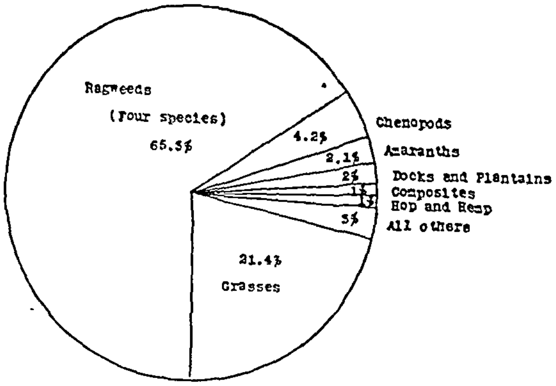

Fig. 4.—Total pollen found on plates calculated from the totals of all pollen plates exposed at the regular stations during the season June, July, August and September; special plates are not included.

The most important of the dozen species of grasses studied is bluegrass. Its wide distribution and intensive production of pollen easily put it in the lead. Redtop and orchard grass command about equal attention. The former sends up blooms to about the height of

those of bluegrass, but it is finer in appearance, while the latter is much coarser and larger. Bluegrass and orchard grass seasons are almost parallel, and they are probably responsible for 80 per cent of the pollen causing the apex of the grass curve (fig. 5). The smaller wave in July is largely due to redtop, but if timothy were more plentiful it would add materially to this wave Quack grass is in bloom at this time also. The weather interfered considerably with results during the latter part of the grass season. Corn pollen seldom reached the plates and never got as high as the Tribune Tower Annual bluegrass, often found in lawns, will bloom when only a few inches high and at any time during the growing season, but does not yield heavily enough to be of much importance Wild rye is a summer grass with a small yield of pollen. The small fall grass peak was due to panic grass.

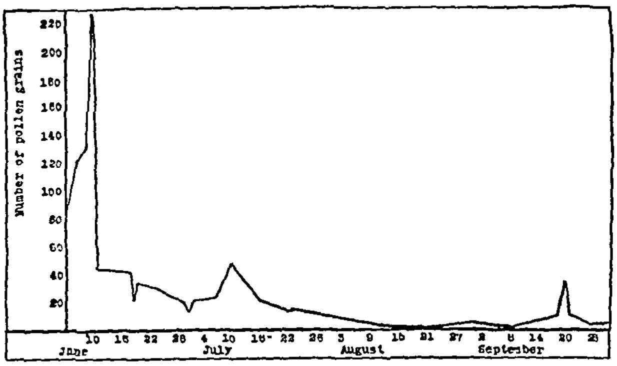

Fig 5—Grass pollen season from average plate counts

Of the five ragweeds found in Chicago, short ragweed and giant ragweed are of about equal importance. The plants of the latter species are not quite so abundant as the former, but are much more productive. These two weeds are largely responsible for the fall pollen season (fig. 6). Burweed marsh elder is similar to giant ragweed in size and shape, with leaves resembling sunflower or cocklebur. It derives its name from the latter resemblance. It has a wide distribution and a short season of intensive bloom, preceding that of the other ragweeds a few days Cocklebur is widely distributed and will thrive where no other weeds can, but it has a low pollen output

Table 6—*Specimen of Special Plate Count* *

August 21 Plate exposed at Sheridan Road and Diversey Boulevard for 24 hours South of Burweed Marsh Elder and Giant Ragweed, 20 300 feet south of Mugwort In line with the wind

	Pollens
Short and giant ragweed	273
Mugwort	293
Burweed marsh elder	487
Chenopods	9
Amaranths	6
Grasses	4
Goldenrod	1

* The plate clearly illustrates the proportion of pollens from the ragweeds and all other plants in the early fall Only one pollen of the goldenrod was found

Lamb's quarter furnishes almost all the pollen from the chenopod group, and pigweed is equally important in the amaranth group. Both should be regarded as of local importance Plantains and docks are of only local importance. They are common lawn and pasture weeds and should be remembered during the grass season. Japanese hop and hemp, though unlike in appearance, are closely related botanically. The former is a vine that is sometimes cultivated, but when it escapes into waste places it will almost cover all other vegetation. Hemp is as large as giant ragweed. Both hop and hemp produce much pollen but are not very abundant.

A number of special plates were exposed for the study of particular species. The results of one of these exposures is shown in table 6. It makes unanswerable argument as to productive ability. As the few mugwort patches are in the northern part of the city, only a very few grains of the pollen ever reached the regular plates, but this plate shows that it could easily cause trouble. It should be noted what burweed marsh elder can do. Sweet clover is probably the most conspicuous plant in the city and has been suspected of causing hay-fever. Considerable time was spent studying it. Strong winds will dislodge its pollen, and it is possible that it may occasionally annoy some one who is brought into close contact with it. Tumbling mustard is also a showy summer weed, but its pollen is blown with much difficulty. Sunflowers and other composites are abundant, but special plating failed to catch their pollens in any quantity. Their pollens may be valuable in treatment of pollen disease caused by their ragweed relatives, but with reasonable care they need never be a causative factor.

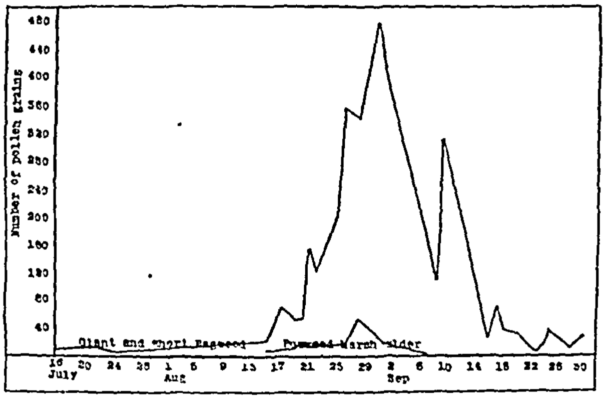

Fig 6—Ragweed pollen season from average plate counts.

POLLEN SEASONS AND WEATHER

The two pollen seasons as shown in figure 7 are not much more than a combination of the grass and ragweed curves (figs 5 and 6). Their relative volume is interesting, that of the spring season being about one fifth of that of the fall season. Wind and rain and the immediate presence of Lake Michigan make noticeable variations in this total curve. Almost every fluctuation is easily traced to one of these causes. During June, the prevailing winds were from the West, bringing grass pollen from the suburban districts and the country. But while the winds were favorable to distribution, at no time during the month were there more than four consecutive days without rain. It will be noted that the peak of the grass season was reached on the day after a strong southwest wind had filled the air with pollen A rainy period in the middle of the month accounts for the sudden drop in the plate counts. The government weather bureau reports the normal number of days of sunshine, clouds and rain for June. During July, August and September, the prevailing winds were mostly from the East and Northeast. However, these lake winds were never as strong as from other directions, and a fairly uniform amount of pollen was found on all slides. As there was no great difference between slides within a few rods of the lake and those miles away during a period of lake winds, it must be assumed that upper air currents carried the pollen out over the lake, and surface winds brought it back.

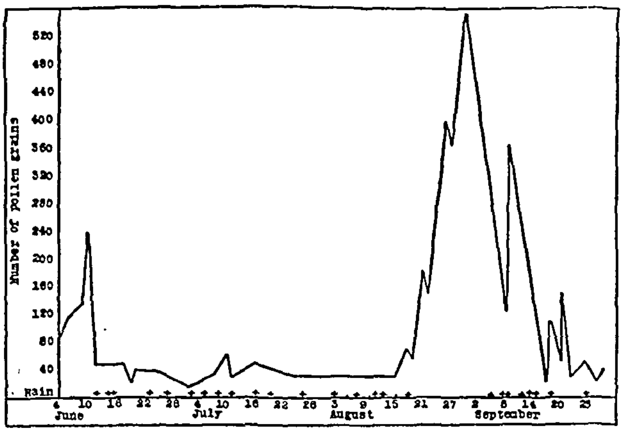

Fig. 7.—Results of total plate counts of pollen of all species.

The fall season began, August 15. With almost no rain from this time until the second week of September, the air became loaded. The two abrupt drops in the curve during early September were due to rains. The records for September 9 and 19 show what a strong Southwest wind can do in stirring up pollen. It is to be regretted that unfavorable weather conditions artificially terminated both pollen waves.

Clinical Notes, Suggestions, and New Instruments

EFFECTS OF INSULIN AND GLUCOSE ON ACID-BASE BALANCE IN SURGICAL DIABETIC PATIENTS *

R. B. GIBSON, PH.D., IOWA CITY

The importance of the preoperative preparation of diabetic patients by building up a glycogen reserve and by administering insulin or insulin and glucose has been repeatedly emphasized.[1] In this clinic it is routine to give our patients 40 Gm. of glucose by mouth or hypodermoclysis and from 5 to 20 units of insulin, according to the severity of the diabetes, from one to two hours before major operations. When insulin and glucose are administered to diabetic patients in this way, there is a distinct shifting of the acid-base balance of the blood plasma to a greater alkalinity, and this change is still evident in the critical postoperative period.

Some determinations of the plasma p_H (Cullen) and of the carbon dioxide (Van Slyke) in diabetic patients are given in the accompanying table. These were all insulin cases. Blood samples were taken before insulin and glucose were administered, just previous to operation, and again from one to two hours after the patients were returned to the ward. In the control tests, essentially the same relations obtained. Patients were operated on under ethylene-ether anesthesia. Postoperative urine specimens were free from acetone and diacetic acid. The action of insulin and glucose so administered is to induce a persisting and only partially compensated alkalosis (Van Slyke). While antiketogenic combustion or "mass action"[2] of the glucose may be considered to some extent responsible, it is probable that a combination of phosphoric acid into a carbohydrate complex[3] frees the strong bases of the tissue and blood phosphates. A new factor influencing acid-base balance is suggested. The insulin "shock" following massive doses of insulin and glucose described by Foshay[4] may well be an alkalosis syndrome.

The Acid-Base Balance After Insulin and Glucose Administration *

Case	Plasma		Blood Sugar	Comment
	p_H	Carbon Dioxide		
1. Fasting.........	....	....	...	No breakfast
Preoperative ...	7.50	73	198	Amputation, thigh
Postoperative...	7.46	69	118	
2. Fasting.........	7.38	50.4	68	No breakfast
Preoperative....	7.40	60.7	245	Cholecystectomy
Postoperative...	7.36	54	332	Glucose by rectal drip
3. Fasting.........	7.43	58	243	No breakfast
Preoperative....	7.51	64	311	
No operation....	7.49	60.7	165	Control test
Shock...........	7.43	57	44	Additional insulin; threshold symptoms
4. Fasting.........	7.45	59.5	83	No breakfast
Preoperative....	7.58	63.3	130	
No operation....	7.53	61.7	104	Control test
	7.50	59.5	128	Breakfast, usual insulin
Preoperative....	7.55	68	228	Amputation, below knee
Postoperative...	7.52	59.5	137	

* All the patients received insulin 20 and glucose 40 except patient 3, who was given insulin 25 and glucose 50.

Austin and Cullen,[5] reviewing some earlier observations, note that the concentration of alkali carbonate and especially the p_H, tend to become abnormally high in diabetic patients treated with an excess of insulin. That the effect is further intensified by insulin and glucose administration in controlled cases and persists even over a period of anesthesia and operative procedure is indicated from our figures. The change is independent of any hypoglycemic state.

GALLSTONES IN CHILDREN

J. D. CAREY, M.D., FORT COLLINS, COLO.

F. B., a girl, American, aged 9 years and 3 months, weighing 65 pounds (29 Kg.), who was referred by another physician for operation for appendicitis, always had been well except for the usual diseases of childhood, until two years previously. Since then, she had had attacks of abdominal pain of such character and severity that she was compelled to be absent from school on an average of four days each month. The pain was located in the right side, associated with vomiting, slight fever and a small degree of rigidity. Attacks would come on suddenly and confine her to bed for a period lasting from two to four days. There was no jaundice or clay colored stools; the bowels were regular, and no digestive disturbance occurred between attacks. The appendix was removed and showed signs of slight chronic inflammation, though not sufficient, in my opinion, to cause the amount of trouble that the girl was having. The pelvis was normal on examination; the gallbladder was greatly distended and an oval stone 1 inch (2.5 cm.) in diameter, was lodged in the common duct. The gallbladder was removed and the wound closed. The recovery was uninterrupted.

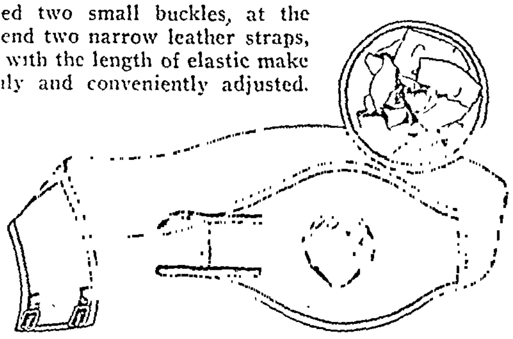
I find that cholelithiasis in childhood is a rare event, and that there have been very few cases reported. Paterson and Wyllie[1] of London reported, in 1925, a case similar to this in which the appendix was removed without relief, and at a later date the gallbladder was examined and five or six small stones were found. Still collected from the literature reports of twenty-four cases in children under the aged of 14; however, in ten of these the condition was of congenital origin, the calculi being discovered in infants who had died within the first few months of life. While this condition is very rare, I believe that every child, irrespective of age, who has an abdominal operation, is entitled to an examination of the gallbladder.

A NEW COLOSTOMY BELT

John W. Neely, M.D, Terrell, Texas

The great boon that colostomy has been to a certain type of colon surgery has, from the esthetic standpoint, always been more or less neutralized by the burden and detriment to the patient's peace of mind, because of the proper care that it necessitates on his part. Therefore, any appliance more convenient, cleanly and comfortable than those now in use is worthy of description.

A patient of mine who has a colostomy has recently designed such a belt. It consists of two parts; the first is the belt, which is made of two pieces of canvas joined by an elastic band. At one end of the belt are attached two small buckles, at the other end two narrow leather straps, which with the length of elastic make it easily and conveniently adjusted.



New colostomy belt.

In the larger piece of canvas there is inserted a metal ring about 4 inches (10 cm.) in diameter. This ring is intended to fit round the two ends of the intestine forming the colostomy, as shown in the illustration. The other part is the colostomy cap, which fits the ring.

To apply the belt, the cap is inserted into the ring and covered with from six to twelve strips of ordinary toilet paper, long enough to reach across the cap. The paper is then pushed into the recess of the cap with the fist and placed over the colostomy. When it is necessary to change, the patient simply grasps the paper by its ends and throws it into the toilet. Advantages of this belt are:

1. It is easy to change, as everything is caught in the toilet paper and thrown away. There is no cleaning, washing or disinfecting.
2. It is convenient, as only toilet paper is used, and nothing has to be carried around for emergency.
3. It is soundless, as the paper muffles sound. The loudest escaping gas may be instantly stopped by a slight pressure on the outside of the clothing.
4. It is odorless, as the paper and cloth check odor in ordinary conditions of the bowels; in extreme conditions, any reliable deodorant can be sprayed on the cap and paper before the belt is applied.
5. It is comfortable to wear; there are no metal parts or bag to cramp or interfere with the freedom of the body.
6. It is not bulky; it permits the clothing to lie naturally, and ordinarily is entirely unnoticeable.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1131)

Effervescent Powders: These are composed of the medicinal agent in admixture with an alkaline bicarbonate and an organic acid. They form a very convenient method of administering various salts in effervescing solution, the effervescence rendering them more agreeable to the palate, more acceptable to the stomach, and favoring their absorption. The effervescence is produced by the presence of nearly molecular proportions of sodium bicarbonate, 83.5 parts, and citric acid, 70 parts, or tartaric acid, 75 parts; or both acids, the citric acid procuring better granules, the tartaric acid being less expensive. When this mixture is thrown into water, the vegetable acid liberates carbon dioxide, which causes the effervescence; a slight excess of acid is generally permitted to give a pleasant acidulous taste. To this effervescing mixture the medicament is added in such proportion that the dose of the powder may be a teaspoonful (about 4 Gm.), a dessertspoonful (about 8 Gm.), or a tablespoonful (about 16 Gm.). The powders are mixed dry. If desired in granular form, they are then granulated by heating them between 93 and 104 C., until the mass coheres sufficiently to form small granular lumps after being rubbed through a coarse sieve. However, the ungranulated powder is just as efficient and useful in every way as the granular powder, and it can be dispensed extemporaneously by the pharmacist.

Effervescent Salts of N. F.

	Dose in 180 Cc. of Water
Effervescent artificial Carlsbad salt, N. F.	4 Gm.
Effervescent artificial Kissingen salt, N. F.	4 Gm.
Effervescent artificial Vichy salt, N. F.	4 Gm.

In addition to these, it has formulas for:

	Average Dose	Containing of Active Ingredient
Effervescent lithium citrate.......	8 Gm.	0.4 Gm.
Effervescent magnesium sulphate..	16 Gm.	8.0 Gm.
Compound effervescent potassium bromide......................	6 Gm.	0.50 potassium bromide 0.25 lithium carbonate 0.05 caffeine

These powders should be kept and dispensed in tightly stoppered bottles, as the moisture of the atmosphere causes a slow reaction to take place between the ingredients, with consequent impairment or even loss of effervescence. When wanted, the dose is put in half a tumblerful of water and taken during effervescence.

Almost any salt or mixture of salts that is nondeliquescent may be prescribed in effervescing form.

---

[1] Paterson, Donald; and Wyllie, W. G.: Abdominal Pain Due to Gallstones, in Child Aged Nine Years, Am. J. Dis. Child. 29: 516 (April) 1925.

* This is the sixteenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

The Pharmacopeia recognizes the effervescing sodium phosphate, the average dose of which is 4 Gm. It is deservedly one of the most popular laxative salines.

The National Formulary contains a number of useful formulas for effervescent salts that enable us to produce artificial mineral waters resembling the natural mineral waters in the essential ingredients.

The writing of extemporaneous prescriptions for effervescent salts is facilitated by remembering that it takes 18 parts of tartaric acid (or 17 parts of citric acid) to neutralize 20 parts of sodium bicarbonate. If, therefore, we desire to prescribe a mixture of sodium salicylate, 1 Gm., and potassium bromide, 2 Gm.,[39] in effervescing form for the relief of migraine, and assuming that a heaped teaspoonful of the finished product might weigh about 5 Gm., we would write:

℞ Sodium salicylate .... 20 Gm.
Potassium bromide .... 40 Gm.
Sodium bicarbonate .... 20 Gm.
Tartaric acid .... 18 Gm.
Dispense in bottle.
Sig. Heaped teaspoonful in tumberful of water every hour, as required, for attack of migraine.

Because it is more portable as well as more permanent and the dosage is more accurate, the dispensing of this prescription in two separate powders like the seidlitz powders, might be preferable. It would then be written:

℞ Sodium salicylate .... 10 Gm.
Potassium bromide .... 20 Gm.
Sodium bicarbonate .... 10 Gm.
Mix and divide into ten blue powder papers.
Tartaric acid .... 9 Gm.
Divide into ten white powder papers.

In the treatment of acute articular rheumatism, the most efficient remedy is sodium salicylate in 1 Gm. doses for a man (0.6 Gm. for a woman). This is usually guarded by sodium bicarbonate (at least 1 Gm.) against precipitation by the hydrochloric acid of the stomach, and by indirect alkali such as sodium citrate[40] (1 Gm.) because some of the phenomena of salicylism are believed to be due to acidosis. To secure the promptest possible systemic action with the least unpleasant effect on the stomach, this mixture is best administered in a tumblerful of effervescing water. Where "seltzer water" is not readily available, it is well to add to each dose the effervescing mixture of 1 Gm. of sodium bicarbonate and 0.9 Gm. of tartaric acid, and to prescribe the acid powder to be dispensed separately in a white powder paper. The remainder of the powder is dispensed in a blue powder paper; and one of each of the powders is mixed in a tumbler three-fourths full of water. The dose is taken every hour until one of three things happens: the pain is relieved, the ears sing, or the patient sweats excessively. Then the dose is given every two hours for several days, then every three hours, and finally every four hours, so as to continue the remedy for at least two weeks after all pain and fever have disappeared. During all this time it is essential that the patient be at absolute rest in bed, even to the extent of using bed pan and urinal. Otherwise, relapses are almost bound to occur.

Teas (species).—These are mixtures of very coarsely comminuted vegetable drugs intended for the domestic preparation of infusions or decoctions. They are a relic of bygone days, when the service of skilled pharmacists was not generally available. Nowadays they are practically never prescribed by physicians, though they are occasionally called for by the laity. To supply this demand, the National Formulary contains formulas for laxative species (St. Germain tea) and pectoral species (breast tea). A teaspoonful of either of these is added to a cup of boiling water, permitted to steep for about ten minutes, strained, and taken while still warm. People should, of course, never be trusted with such unreliable and irresponsible preparations of potent remedies.

TABLETS

Tablets are medicated powders formed into disks of convenient size, without the use of a cohesive. When a cohesive is used, the result is spoken of as a lozenge. Tablets that are slow in disintegration are essentially pills. Tablets are most commonly made by compression in a machine (compressed tablets). They may also be prepared by mixing the powder with a volatile liquid so as to form a mass, which is then molded into disk shape by means of a suitable apparatus, and exposed to the air dry. The result is a tablet triturate.

By whatever process these disks are made, they may be considered acceptable if they meet the following requirements: When placed in water they should disintegrate within a few minutes, and with the aid of not more than gentle agitation. When dry, they should be crushable into powder without difficulty by the pressure of a thumb. Still, they should possess sufficient firmness so as not to crumble and wear away at the edges when subjected to ordinary handling.

Compressed tablets usually differ from tablet triturates not only in containing pure medicaments without diluents, and in being made by compression machines, but also in shape, having oval instead of flat faces. Substances in the form of granules or small crystals can readily be compressed into tablets without preliminary manipulation. Fine powders must be formed into granules before they can be satisfactorily fed to the tablet-making machine. This accounts for the mottled appearance of many compressed tablets containing mixtures.

A matter of the greatest possible importance is the rate of disintegration of the tablet. Unless the tablet is to be used as a lozenge or intended to act as a pill, speedy disintegration must be secured. Improperly compressed tablets containing insoluble substances have been known to pass through the entire alimentary tract and to appear undissolved in the stool. Hence compressed tablets containing slowly soluble or insoluble bodies, such as quinine sulphate or charcoal, must be made so as to disintegrate rapidly, which can be done by the admixture of either starch, which swells in water and thus disintegrates the tablet, or of sodium bicarbonate and citric or tartaric acid, which by their effervescence produce disintegration. Such tablets must be kept carefully protected against moisture; otherwise, the "disintegrating" agent will become ineffective. Resinous substances should not be prescribed without liberal admixture of a soluble diluent, as otherwise they may not disintegrate. The addition of a slight trace of liquid petrolatum is also useful in preventing the drug from packing too firmly together.

The "tablet triturate" possesses certain advantages over compressed tablets; indeed, over other solid dosage forms. Well made tablet triturates disintegrate immediately on being placed in water; thus, they have the same degree of solubility as powders, over which they have the advantage of being swallowed more readily and conveniently. They are more soluble than capsules, pills and compressed tablets. They are prepared by triturating the medicament with sucrose, lactose or other inert soluble substances, and then moistening the powder with sufficient alcohol to make a paste. This is pressed into molds consisting of a plate perforated with holes of the desired size of the tablet. The tablets thus shaped are pressed out of the holes by means of another plate having pegs that accurately fit the perforations. When the alcohol evaporates, which requires only a few minutes, the tablets retain their shape and are ready for use.

---

[39] Sodium bromide is less desirable for this purpose, as it absorbs moisture from the air.

[40] Potassium citrate is deliquescent.

Tablet triturates are generally made to weigh about 0.05 Gm. each; hence they are suitable for the administration only of medicines the dose of which is small, such as calomel, morphine sulphate, aconitine, and arsenic trioxide. The "hypodermic" tablets so useful for the preparations of solutions for injection are prepared in this manner.

The tablet saturate might also be referred to here, though it is rarely used nowadays. It is a sugar tablet, originally made without medication (so-called blank tablet), which is medicated by the addition of a drop of alcoholic solution. The alcohol is then allowed to evaporate. Obviously, aqueous or weakly alcoholic fluids cannot be used for this purpose.

Substances that are unsuitable for prescribing in powder form are also not fit for tablet administration. Suitable for this purpose are those powders whose dose is small; at any rate, not much larger than 0.3 Gm., the usual size of compressed tablets. If the dose is much smaller, it is converted into a trituration by being mixed with sugar of milk, sugar or other diluent powder, and formed into a tablet triturate. For large doses, several tablets may be taken at one time. Tablets as large as 1 Gm. are made; but these are intended for solution before use.

Tablets have become, within the few years of their existence—they were introduced by Dr. Robert M. Fuller in 1878—one of the most popular of administration forms. This is because, by means of suitable machinery, they can be manufactured very cheaply on a large scale; and manufacturers have done their best to introduce them, most especially among physicians who dispense their own medicines. To retail pharmacists, on the other hand, tablets have not been very welcome, partly because they are somewhat more troublesome to prepare on a small scale than powders, capsules or pills, but chiefly because they require a special machine. This is rather unfortunate, because for certain purposes extemporaneously made tablets are unexcelled. It is also a rather erroneous attitude on the part of the druggist, because small, inexpensive tablet machines operated by hand are on the market, and the technic is certainly not beyond the powers of comprehension and skill of a well trained pharmacist. However, as the situation stands at present, physicians should not prescribe other than ready-made tablets, such as they know the pharmacist carries in stock, unless they are so fortunate as to have available the services of a pharmacist sufficiently interested and ambitious to equip himself to prepare tablets extemporaneously. Even then it will be more convenient and less expensive for the pharmacist to have all those tablets that are used very extensively manufactured by power driven machines.

Tablets are sometimes swallowed as a whole. Then they have no advantage over pills or capsules other than the manufacturer's convenience. They may be dissolved before use, as is done with hypodermic tablets and with those intended for topical employment, as, with the official poison tablets of corrosive mercuric chloride. These weigh 1 Gm., and contain 0.5 Gm. of corrosive mercuric chloride, with sodium chloride or ammonium chloride forming the remainder. They are colored blue, made of angular shape, preferably coffin-shaped, not discoid, and directed to have the words "poison" and the skull and cross bones design distinctly stamped on them. Another example of tablet for topical use is "Seiler's tablets," which, dissolved in a wineglassful of water, yield an alkaline lotion suitable for nose or throat.

A special use for tablets in which they are unexcelled is for "candy medication," an administration form especially suitable for children. The idea of presenting medicine in candy form is as old as are confections and lozenges. These have not become generally popular, because what is sometimes called palatable is not always really delicious. To be successful, candy medication[41] must meet the following requirements: It must be a perfectly delicious sweet, attractive in form, color and odor, and free from the suspicion of disagreeable or medicinal taste or odor. It must disintegrate rapidly in the mouth, for a sick child will usually not suck candy as a healthy youngster would. These requirements are met by sugar tablets, medicated with tasteless or nearly tasteless and yet active substances. Modern synthetic chemistry has enriched our resources in this respect to a surprising degree.

The new National Formulary will contain formulas for the following sweet tablets, which may be prescribed by merely giving the official name: tablets of mild mercurous chloride, each containing 0.006 Gm. of mild mercurous chloride; tablets of phenolphthalein, containing 0.06 Gm. of phenolphthalein; tablets of santonin, containing 0.03 Gm. of santonin, and compound tablets of santonin, containing 0.03 Gm. of santonin and 0.03 Gm. of mild mercurous chloride.

Quite a number of other substances can be given in the same form. Were a general formula for a base for sweet tablets desired, it might be found in the formula for vanilla cacao sugar.

Vanilla Cacao Sugar

Tincture of vanilla	5 Cc.
Cacao powder	10 Gm.
Dextrose*	10 Gm.
Sucrose, powdered	80 Gm.

Mix thoroughly by trituration in a mortar, and preserve in a well stoppered bottle.

* The dextrose seems to be of advantage in the shaping of the tablet by the machine, but is not absolutely necessary.

Mixing this sugar preparation with the proper amount of medicament in such proportion that it is contained in 0.3 Gm. yields a powder that is ready for compression in the tablet machine. This forms a fairly satisfactory vehicle for children's doses of saccharated ferrous carbonate, arsenic trioxide, phenetsal (salophen), atropine sulphate, methenamine (hexamethylenamine U. S. P. IX), calcium iodobehenate (sajodin), terpin hydrate, albumin tannate, and a number of others.

For substances that have a slight flavor of their own, such as thyroid, sulphur or podophyllum, cinnamon cacao sugar is better. The latter may be prepared by substituting 0.5 cc. of a 10 per cent spirit of cinnamon for the tincture of vanilla in the formula for cacao sugar. A number of almost insoluble substances of slight but lingering taste (quinine ethyl carbonate, acetphenetidin, digitalis, ipecac) can be made perfectly pleasant by impregnating them with gluside (saccharin) by trituration with a 2 per cent alcoholic solution of gluside containing also 2 per cent of tolu,[42] and permitting the alcohol subsequently to evaporate.[43]

---

[41] Fantus, Bernard: Candy Medication, J. A. M. A. **66**: 26 (Jan. 1) 1916; St. Louis, C. V. Mosby Company, 1915.

The prescribing of ready-made tablets is very simple. We write:

℞ 15 tablets of mild mercurous chloride (N. F.).. 0 006 Gm.
Label: One every hour until six, five, four are taken on three successive days.

When extemporaneous tablets are desired and a pharmacist is available who is equipped to make them, it is customary to designate the quantity of medicament wanted in the total number of tablets and the total quantity of diluent to be used to make up tablets of the desired weight (0.18 or 0.30 Gm.) and to order the pharmacist to divide this powder into the required number of tablets. Thus, should we desire to prescribe sweet tablets of arsenic trioxide and ferrous carbonate, we might write:

℞	Arsenic trioxide	0 03 Gm
	Saccharated ferrous carbonate..	2 00 Gm
	Cacao (10 per cent) sugar, vanilla flavored .	8 00 Gm

Divide into thirty tablets
Label: One three times a day after meals.

Besides the sweet tablets mentioned, the National Formulary will contain a formula for tablets of sodium bicarbonate (0.25 Gm. each, flavored with oil of peppermint), the "soda-mint" tablets, so popular with certain dyspeptic patients. There is also a formula for charcoal tablets, each of which contains 0.3 Gm. of animal charcoal, any required number of which one would rather swallow than to drink a suspension of the powder in water. The same might perhaps be said of the tablets of sulphur and potassium bitartrate, which contain only 0.2 Gm. of washed sulphur and 0.06 Gm. of potassium bitartrate, so that quite a number of them will have to be taken to constitute a medicinal dose.

Confections.—Confections, also known as electuaries, are soft, pasty solids composed of medicinal agents, sugar and flavoring matter intended to be eaten, or dissolved in the mouth, like candy. They were never very popular, and are now used even less frequently than formerly, having been displaced by their dosage form, the lozenges. Confections are dispensed in jars or in wide mouthed bottles. Small lumps of a size approximating some familiar object, or spoonfuls are directed to be taken at a time. Inexactness of dosage is one of their disadvantages, and they do not keep well.

Only two confections are official in the National Formulary: the confection of rose and the confection of senna. The former might be considered a basic confection to be suitably medicated. The latter, a laxative that might be given in 4 Gm. doses even to a child, is not much used or generally kept in drug stores, probably because a more pleasant confection can be prepared at home by mixing equal parts of senna leaves, figs, seedless raisins, and prunes and dates, freed from stones. These are chopped and mixed in a chopping bowl, and rolled into cylinders as thick as a thumb, to be cut into slices of a size appropriate to the size and age of the patient.

A domestic recourse, not sufficiently resorted to in pediatric practice, is to prescribe the medicine—which must be relatively inoffensive—in powder form, and to have it made into a confection at home by admixture of any desired marmalade or sweet preserve.

(To be continued)

[43] Detailed working formulas for these have been published in the Journal of the American Pharmaceutical Association (10: 533 [July] 1921).

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1925, p. 360).

The Cutter Laboratory, Berkeley, Calif.

Typhoid Paratyphoid Prophylactic.—Marketed in packages of three vials, one vial containing 500 million killed typhoid bacilli, 375 million killed paratyphoid A bacilli and 375 million killed paratyphoid B bacilli per cubic centimeter, and two vials each containing 1 billion killed typhoid bacilli, 750 million killed paratyphoid A bacilli and 750 million killed paratyphoid B bacilli per cubic centimeter; in packages of one 20 cc. vial containing 1 billion killed typhoid bacilli, 750 million killed paratyphoid A bacilli and 750 million killed paratyphoid B bacilli per cubic centimeter; and in packages of one syringe containing 1 billion killed typhoid bacilli, 750 million killed paratyphoid A bacilli and 750 million killed paratyphoid B bacilli per cubic centimeter.

COD LIVER OIL.—Oleum Morrhuae.—For description see the U S. Pharmacopeia and Useful Drugs.

Parke, Davis & Company's Standardized Cod Liver Oil.—It has a content of fat soluble vitamin-A which is not less than 440 units per gram, and an antirachitic potency of not less than 59 units per gram.

Dosage—Infants, from 1 to 2 cc. (15 to 30 minims); older children, from 2 to 4 cc. (30 to 60 minims); adults, 4 cc (1 fluidrachm) or more, three times a day.

Manufactured by Parke, Davis & Co, Detroit. No U. S. patent or trademark

Parke, Davis & Company's standardized cod liver oil complies with the standards of the U S Pharmacopeia. In addition, it is required to have a content of fat soluble vitamin A, determined by the method of the U S P, equivalent to 440 units (one unit being the amount required to correct both the induced xerophthalmia and retarded growth of young albino rats) and an antirachitic potency when determined by the method of McCollum, Simmonds, Shipley and Park (*J. Biol. Chem* **51:** 41 [March] 1922) of not less than 59 units (one unit being the amount of cod liver oil required daily to initiate recalcification in the leg bones of young albino rats).

PITUITARY SOLUTION, U. S. P. X OBSTETRICAL-WILSON.—An extract of the posterior lobe of the pituitary body of cattle, preserved by the addition of chlorbutanol, each cubic centimeter containing 0.005 Gm. It is standardized by the method of the U. S. Pharmacopeia to have the strength of Solution of Pituitary, U S P.

Actions, Uses and Dosage.—See Pituitary Gland, New and Nonofficial Remedies, 1925, p. 260.

Manufactured by The Wilson Laboratories, Chicago No U. S. patent or trademark

Ampoules Pituitary Solution, U S. P. X Obstetrical Wilson, 0 5 cc

Ampoules Pituitary Solution U S. P X Obstetrical Wilson, 1 cc.

SCARLET FEVER IMMUNITY TEST (See THE JOURNAL, Jan 16, 1926, p 199).

Lederle Antitoxin Laboratories, New York

Scarlet Fever Streptococcus Toxin for the Dick Test Lederle—Prepared by growing the scarlet fever streptococcus in broth, using culture Dick I or Dick II obtained from the Hygienic Laboratory or culture no 55 4 obtained from the New York City Department of Health Marketed in packages of one vial containing toxin, which has been diluted with physiological solution of sodium chloride and preserved with 0 25 per cent of phenol sufficient for ten tests; in packages of one vial containing 0.1 cc of a concentrated toxin solution containing 66 6 per cent glycerol, sufficient for 100 tests, and a vial of 10 cc of physiological solution of sodium chloride containing 0 25 per cent phenol for diluting the toxin, so that 0 1 cc of the dilution will give a typical Dick reaction

Scarlet Fever Streptococcus Toxin Lederle—Prepared by growing the scarlet fever streptococcus in broth, using culture Dick I or Dick II obtained from the Hygienic Laboratory or culture no 55 4 obtained from the New York City Department of Health Marketed in packages of four vials of toxin diluted with physiological solution of sodium chloride containing 0 25 per cent phenol and containing, respectively, 500, 1,000, 2,500 and 5,000 skin test doses; in packages of four 20 cc vials of toxin diluted with physiological solution of sodium chloride containing 0 25 per cent phenol and containing, respectively, 500, 1,000, 2,500 and 5,000 skin test doses per cubic centimeter, in packages of forty vials of toxin diluted with physiological solution of sodium chloride containing 0 25 per cent phenol, ten containing 500 skin test doses, ten containing 1,000 skin test doses, ten containing 2,500 skin test doses, and ten containing 5,000 skin test doses

DEXTROSE (See THE JOURNAL, Dec. 12, 1925, p. 1891). The following dosage form has been accepted:

Ampules Dextrose 50%, 50 cc—Each ampule contains 50 cc of a 50 per cent solution of dextrose, U. S P.

Prepared by Swan Myers Company, Indianapolis.

THE PATHOLOGY OF SCURVY

General knowledge of the pathology of scurvy dates back to Lind's classic Treatise on the Scurvy, published in 1772. Hess[1] has designated Barlow's publication in 1883, establishing the identity of the scurvy of adults and of infants, as the modern milestone in the study of the disorder, so that "Barlow's disease" is no longer looked on as a distinct entity. The theories of its etiology have been varied. For many years the potassium deficiency theory, suggested by Garrod, gained wide acceptance. That scurvy should be attributed to a lack of this element is, as Hess remarks, readily comprehensible in view of the abundance of potassium in the antiscorbutic foodstuffs, the fruits and the vegetables. The citric acid theory had "a short but popular career," as did the hypothesis including acidosis as the etiologic factor. Not a few persons have held to a theory of toxic injury, believing that poisons responsible for the appearance of scurvy are either consumed in the food or formed in the bowel by bacterial agencies. Toxins of alleged microbic origin have formed a favorite theme, almost since the birth of modern bacteriology, for exploitation in relation to the genesis of disorders of obscure origin; there has often been a sort of contest for favor in the eyes of students between the postulate of a specific detrimental bacterium and the mysterious pathogenic toxin. The hypothesis that scurvy is an expression of severe constipation had a short-lived existence, because the known facts will not square with it. Today there is all but universal acceptance of the interpretation of scurvy as an avitaminosis—an expression of the lack of the labile vitamin C in the diet. The vitamin hypothesis has been tested experimentally on various species, beginning with the investigations of Holst and Froelich in 1912. As a result, it has become possible to reproduce the symptoms, to test remedial agents, and to examine in detail the defects when they arise in the organism as well as the reparative changes induced by antiscorbutic treatment.

In the study of the histopathology of scurvy, lesions of the bones were early identified and established as characteristic. Hess has pointed out that attention was focused so exclusively on the bones that for many years, indeed until recently, the other organs of the body were neglected. This is true of the gross as well as of the microscopic anatomy. Consequently, more than usual interest centers in the detailed investigations of Wolbach and Howe[2] of Boston on the morphologic concomitants of the condition of complete scorbutus and the immediate responses in repair. In the introductory contribution to the newly launched *Archives of Pathology and Laboratory Medicine*, published by the American Medical Association, Wolbach and Howe characterize scurvy as inability of the supporting tissues to produce and maintain intercellular substances. Direct proof of this conclusion has been obtained in study of teeth in regard to dentin, in the study of growth and repair of bone in regard to bone matrix, and in the study of repair of soft tissue in regard to the collagen of connective tissues. Localized hemorrhages are a common and conspicuous symptom in scurvy. These studies suggest that the extravasations of blood may be due to a lack of cement substances in the blood vessels, in harmony with the researches of Aschoff and Koch[3] on human material. Wolbach and Howe assert that the proliferative power of epidermis, endothelium, fibroblasts and osteoblasts is not diminished in scorbutus. They believe that the failure of capillary formation can be explained reasonably, according to knowledge of other intercellular substances, as due to failure of endothelial cells to form cement substance. In the light of their histologic examinations, the Boston pathologists advance the theory that the failure of cells to produce intercellular substance in scorbutus is due to the absence of an agent common to all supporting tissues which is responsible for the setting or jelling of a liquid product.

Such considerations suggest a new approach to the study of the physiology of intercellular materials. It is noteworthy that the various avitaminoses are beginning to show their histologic pathogenesis. The more spectacular features of vitamin deficiency—the subtle modes of production, the astounding recoveries, and the minute amounts of actual dietary substance that determine nutritive success instead of disorder—are being supplemented by the laboriously secured substantial evidences of the underlying morphologic changes. Only recently, occasion arose to record[4] the fact, likewise contributed by Wolbach and Howe,[5] that in protracted deprivation of fat-soluble A vitamin, keratinization of epithelial tissues is the conspicuous pathologic defect. There is a widespread tendency for a transformation of secreting and ductal columnar epithelium, or of transitional epithelium, into the heavily hornified type normally serving for protective purposes. Long known to occur in the eye and parocular glands, the change is now recognized as a more general one in this type of avitaminosis. Following lack of vitamin B, the nervous tissues may become involved; with a shortage of vitamin A it is the epithelium, and in deprivation of vitamin C the connective tissues that are profoundly affected. Such knowledge, firmly established, represents a marked step in advance in the domain of pathogenesis.

PRECAUTION IN TONSILLECTOMY

The much discussed problems of tonsillectomy are difficult to approach from any angle without emerging into controversial opinion. The debate frequently is not a calm discussion based on ascertainable facts or indications, but an outburst of fixed convictions delivered with insistence on a preconceived theory. Let us insist at the outset that tonsillectomy has not only its positive indications but also certain presumptive advantages in the pursuit of health: a diseased tonsil is an admitted menace.[1]

Whatever the uncertainties regarding the needs of tonsillectomy may be, there is growing evidence that the operation should not be too lightly regarded. Not every person is included in statistically favorable records of operative benefit. The very circumstance that now and then some writer regards it as worth while to designate the removal of the tonsils emphatically as a major operation directs attention to the uncertainties cropping out in medical minds. In the case of the major risks, the surgeon inevitably dwells on preoperative needs and postoperative dangers; he attempts to foresee and forestall unfavorable consequences.

The growing prominence of tonsillectomy in everyday practice has accordingly attracted attention to possible unpleasant sequelae. To some of these Daland,[2] for example, has directed attention, reviewing the disagreeable complications represented by abscess formation. Myerson,[3] too, has stressed the importance of careful preoperative survey to rule out pulmonary disease and other menacing conditions in the pulmonary tract. A particularly important observation has lately been stressed by Zingher,[4] as the result of his experience in the New York City Department of Health. He has pointed out that diphtheria is likely to develop in a patient who has just been submitted to tonsillectomy and adenoidectomy, if the person is susceptible, as can be shown by a positive Schick test, and if he is a carrier of virulent diphtheria bacilli. While these three factors—absence of general immunity to diphtheria, presence of virulent diphtheria bacilli in the nose or throat, and an operation, such as tonsillectomy—may not come together frequently, Zingher believes that when they are present in the same person diphtheria is quite certain to follow and the disease is likely to prove unusually dangerous. The serious nature of the superimposed diphtheria arises, he adds, from the danger of an early and rapid absorption of a fatal dose of toxin from the extensive raw surface, and the difficulty of recognizing the disease in the sloughing postoperative membrane until much valuable time has been lost and the opportunity for effective administration of antitoxin has slipped by. Diphtheria may also readily develop as a result of a superimposed infection with diphtheria bacilli occurring in a susceptible person from one to two weeks after an operation on the tonsils and adenoids. At this time, the wound has not yet completely healed, and the resistance of the mucous membrane to infection is still below normal.

These considerations are borne out by the records of actual large clinical observation. In view of the findings reported, Zingher recommends that nose and throat cultures for diphtheria bacilli be taken as a routine before such operations as tonsillectomy and adenoidectomy. If the cultures are positive, a prophylactic dose of diphtheria antitoxin should be administered if necessary. In carriers who are to be treated by the removal of tonsils and adenoids, it is especially important to make certain that the patient either gives a negative Schick reaction, or, if a positive Schick reaction is obtained, that he receives a prophylactic dose of diphtheria antitoxin.

The foregoing observed features of tonsillectomy emphasize in a new way the local resistance of the intact normal mucous membranes against invasion through infectious micro-organisms. The regional protection of carriers against localized pathogenic forms and their toxic products represents a mode of highly effective defense that deserves to be better understood. It appears that successful invasion by one harmful infectious agent, such as the diphtheria organism, may break down the previously competent local protection against another harmful implanted form, such as the germ of scarlet fever. In other words, the scarlatinal streptococcus may be present in the throat passages but remain harmless for the time being, until the attack of diphtheria destroys the local resistance of the mucous membrane to infection with this pathogenic organism. Just as the local resistance of the normal mucous membrane may be destroyed by an inflammatory process such as a cold or an infection, it may be impaired by tonsillectomy. Trauma may destroy the nonspecific local protection of the patient.

THE SPLEEN IN MEASLES—AN OVERLOOKED SYMPTOM

In the course of the current popular pastime of subjecting medicine to criticism from every conceivable angle, it has sometimes been intimated that the twentieth century physician is endeavoring to become a biophysicist and a biochemist rather than a clinician. Generalization of any sort is a venturesome procedure, particularly when it fails to rise above the haphazard method of jumping at conclusions. When a student of the present generation is reminded of "the golden age of bedside diagnosis" in which the unaided organs of sight, sound and touch were trained to remarkable accomplishment, he sometimes wonders whether, after all, the armamentarium of instruments of precision and the cyclopedia of test reactions that he has acquired in the course of his modern training are to be a handicap rather than a help. He reads the admonition of the late Sir James Mackenzie,[1] who, while far from decrying the importance of the advances that have been made by so-called laboratory methods of clinical diagnosis, frankly rates their practical value to the general practitioner as small compared to the information to be gained by recognition of symptoms through avoidance of "the more intricate methods of examination."

Perhaps the student will begin to wonder whether he shall discard his thermometer, stethoscope and manometer. Let him take courage, incentive and inspiration from the fact that the devotees of the simpler methods have not exhausted the possibilities of discovery. One might suppose that none of the common manifestations of a universally familiar disease such as measles had escaped recognition. Verily, physicians unhampered by microscopes or test tubes have observed generation after generation of measles patients. Yet it remained for Koplik,[2] only thirty years ago, to emphasize the significance of the oral rash and mouth spots that commonly bear his name. And only now has it at last been made unmistakably clear through the records of Bleyer[3] of the St. Louis Children's Hospital that enlargement of the spleen should be included in the symptomatology of measles.

He remarks that it is, of course, a common thing in clinical work to encounter a spleen that can be felt below the costal margin; but the almost abrupt appearance of the spleen during the eruptive stage of measles, and the suddenness of its disappearance as the rash subsided, were quite unexpected and prompted an inquiry into the frequency of this phenomenon in this disease. The enlargement is evidently related to the virus of the disease. The change in the spleen is coincident with the eruptive stage of this disease, both as to appearance and as to disappearance, the greatest enlargement as to frequency and size being noted on the third and fourth days of the rash. Contrary to what might be expected, the severity of an attack in these patients does not seem to make the occurrence of enlargement of the spleen higher than is found to be the case in those that ran a milder course. And all of this is the simple finding regarding one of the largest organs in the body in the examination of a few hundred sick children, while half a hundred textbooks have denied, disregarded or debated the symptom.

Current Comment

COLLEGE PHYSICAL EXAMINATION THE START OF A LIFE HABIT

Health examinations on entrance into college or university are becoming the rule rather than the exception. In the majority of institutions, the examination is given after the student has matriculated. Sixty-eight of 152 institutions require the examination before the student is admitted. Of these, fifty-two require that the examination be performed by a college physician; and the remainder, that the student possess a certificate of health from his family physician.[1] The advantages of having the examination made by the college physician who will be in charge of the student's health for the next four years, and of having this examination prior to matriculation, are obvious. The danger is that the enormous amount of work that must be crowded into a few days will lead to undue haste. At the College of the City of New York, where an examination before admission has been required for fifteen years, the danger of haste has been obviated by having numerous examiners and recorders on the spot and by instructing in detail each participant, whether clerk, examiner or examinee, exactly what he is to do and when. In addition, instructions are furnished to meet the emergencies that will arise when some person fails to live up to the system. Perusal of these instructions gives the impression of a multitude of definite objectives, intricately synchronized, as highly developed as a battle offensive. The numerical results at the College of the City of New York are important. They show that students who could not hope to stand the gaff in college or who might be a menace to their associates were excluded from college or their admission was deferred until their physical condition had been sufficiently improved. These results also show the basis on which physical defects were followed up and corrected. But tabular results have no place here, and it may be that the most important objective of all is expressed in the words, "We regard this health examination program as a part of an earnest endeavor to give these boys a convincing experience with scientific medical examinations. We will measurably fail in our work if we do not produce in these young citizens in the making the custom of periodic health examination and the experienced selection of scientific health service after graduation."

VETERANS' BUREAU TEST OF CLINICAL THERMOMETERS

An article in this issue[1] presents to many physicians their first knowledge of how a clinical thermometer is manufactured. In part, this article attempts to show that the reputable manufacturer of a clinical thermometer is worthy of confidence and that it is unnecessary to hedge him in with legislation which will increase expense to the physician and the public. Recently, the Veterans' Bureau has had tested 508 thermometers taken at random from a purchased lot of 6,000. The published result[2] shows that "about 3 per cent would be unreliable and about 2 per cent would have unduly large errors." Although this is not a perfect score, it is a creditable one. In this instance, without compulsory legislation manufacturers have demonstrated the intention of turning out dependable instruments. On payment of a small fee, any one can have his thermometers checked by the Bureau of Standards.

KAOLIN IN INTESTINAL DISEASE

Chinese medicine is giving way to Western scientific medicine even in China. Nevertheless, through centuries of experience, Chinese physicians have discovered a number of remedies which Western physicians now use.[3] In Western countries, kaolin has been used in the manufacture of porcelain and toilet powder. Pharmacists have used it as a filtering material, as a base for poultices (cataplasma kaolini, N. F.), as an excipient in the making of pills, and as a dusting powder for wounds and ulcers. It has been recommended for gastric hyperacidity. For centuries, Chinese physicians have used kaolin in fevers and intestinal disorders, including cholera. In the latter part of the nineteenth century, it was being used by Julius Stumpf of Wurzburg, externally for septic wounds and ulcers, and internally in large doses for Asiatic cholera.[4] At the present time experiments[5] seem to confirm the scientific basis of its use. Work in vitro, on animals and on man has demonstrated that it is not an antiseptic agent but that in fluid mediums, if kept in motion, kaolin will carry down with it large numbers of bacteria. More than this, it combines with the toxins and toxic products of cholera, of the typhoid dysentery group of organisms, and, apparently, with putrefactive and proteolytic bacteria. In this way, from 30 to 60 Gm. administered daily will change the intestinal flora of an adult from a predominantly proteolytic to an aciduric type. Recent workers in the field have successfully employed kaolin in Asiatic cholera, bacillary dysentery, chronic ulcerative colitis and acute enteritis. A corollary of this important finding will be that certain groups of inexact thinkers will enlarge on the fact that superstitious and empiric practitioners used kaolin centuries before pharmacology and scientific medicine recognized its value. An accurate mind, however, will recall that the same school of medicine that discovered the use of kaolin also credited the ashes of an ancient comb as a remedy for hairball in the stomach.

AMERICAN IDEALISM IN PUBLIC HEALTH

Geographic distance furnishes sometimes a perspective that permits clear evaluation of accomplishments. A recent Brazilian author[1] has traced the development of modern preventive medicine, dividing it into three periods: the work of Chadwick and the English school; Pasteur and Koch's contributions; American idealism. While the two first steps were epoch making, the actual prevention and control of epidemic diseases depended on the organization of an efficient public health service. This is the task which, according to Clark, the United States has successfully performed for the last twenty years. It demanded a combination of such rare qualities as idealism, philanthropy, generosity, daring, perseverance, and devotion to duty. These the Brazilian scientist could find nowhere else in his historical survey, thus justifying America's leading rôle in modern social medicine. Americans were the first to understand the need of reforming medical education in order to cope with the many-sided problems of social medicine. Their altruism led them to establish public health schools, not only in their own country, but abroad—Brazil, China, England. "American prominence in health work is so obvious that even London, the capital of aristocracy, is reorganizing its university and equipping its public health school with American money." This international spirit in itself represents a contribution of the first rank to modern hygiene. As instances of the practical American spirit, Clark cites the creation of small scattered laboratories, pure food laws, industrial sanitation, hospital service, milk safety campaigns, canned goods, and even the Volstead law. Clark also renders a tribute to the banishment of the terminal disinfection bugbear by the health officer of Providence, R. I. His name, however, is given as Charles Chaplin. One may depend on foreigners for perspective and even appreciation, but when it comes to spelling names, the mind sometimes succumbs to Hollywood.

LACTIC ACID AND MUSCULAR FUNCTION

"The problem of the activity of muscle," Meyerhof has written, "has accompanied physiology, so to speak, from the cradle." It is nothing more than the question as to how chemical energy is transformed in the body into mechanical work. The older theories that the performance of a muscle during contraction is closely analogous to what happens in a heat engine have been abandoned. An acceptable hypothesis, as Howell has pointed out, should explain the mechanism by means of which the shortening of the muscle is produced, the

nature of the energy which is thus transformed into mechanical work, and the origin of this energy from the chemical reactions that take place in the stimulated muscle. Apparently this tissue is a chemodynamic machine in which chemical energy is converted to work without passing through the form of heat. The demonstration of the appearance of lactic acid during contraction in the lack of oxygen or in rigor, and its disappearance on oxidative recovery of the muscle, formed what has been termed the first bridge between *the biochemistry of muscle and its performance* of work. According to the Hill-Meyerhof theory of muscle action, carbohydrate is converted into lactic acid, which is subsequently in part destroyed by oxidation and in part transformed into glycogen retained in the contractile tissue. The genesis of the lactic acid thus becomes a very significant feature of the process. There have been various speculations as to the immediate precursor of the lactic acid in its production from sugar in muscle. Meyerhof,[1] whose work in this field has earned him a Nobel prize, has lately championed methyl glyoxal, $CH_3.CO.CHO$, a carbohydrate derivative readily transformed by tissues and tissue extracts into lactic acid, $CH_3.CHOH.COOH$, under suitable conditions. The successive steps from muscle glycogen to muscle lactic acid are likely soon to be demonstrated with some approach to accuracy in the attempted explanation of what happens during the act of contraction.

AMERICAN CONFERENCE ON HOSPITAL SERVICE

Dr. Sigmund S. Goldwater, New York, in the Chair

February 18

Individual Versus Group Responsibility for the Care of the Hospital Patient

Dr. S. S. Goldwater, New York: The American Conference on Hospital Service is a delegate body made up of representatives of some nineteen national organizations that have a common interest in hospital betterment. Hospital methods, standards and practice cannot be ignored in any survey of medical education. The standing of a hospital might to a certain extent be gaged by the number of consultations that took place between members of the various clinical branches of the service.

Dr. Henry A. Christian, Boston: This address was published in full in the Hospital Number of The Journal, April 3, 1926, page 993.

Dr. Hugh Auchincloss, New York: This address was published in full in the Hospital Number of The Journal, April 3, 1926, page 995.

The Adaptation of Medical Education to Changing Clinical Practice

Dr. Louis B. Wilson, Rochester, Minn.: The changes occurring in clinical practice do not affect materially the great body of medical practice. *Only good, general medical education* and good horse sense are necessary for the care of the bulk of patients. Attention is so apt to be turned to the special condition that we forget these things. In some things, medical practice is changing; first, I think, in the type of the patient. Most of the changes are coming in the field of occupational diseases. More than this is the change in additional methods of diagnosis. Third, there is a great change in the additional methods of treatment. What are the relationships of the hospital to these factors? The medical graduate is to receive his knowledge of occupational diseases in the hospital. The second new type of patient is the group of the supposedly well, the possible sick. The hospital has a very large responsibility in maintaining a diagnostic clinic for inspectorial service to the well who may possibly be sick. Mrs. Jones comes to us from a renter's farm in northern Iowa. She has heart disease. We undertake to tell her how she shall live. She is told by a man who has no conception of the conditions on that renter's farm. Should not the hospital, then, get in closer touch with the home conditions of the patient? The same is true of the mental hygiene of the patient. Are we giving enough attention to this in the hospitals?

Dr. Allen O. Whipple, New York: I shall deal with only one phase of this subject; namely, the organization of the university hospital outpatient clinic in its relation to clinical teaching. The university outpatient clinic should have the following features: It should occupy a central position in the hospital in close contact with the ward and laboratory units. The attending men on the ward services should work in the outpatient clinic, in the consultation and follow-up units. The men holding senior positions in the outpatient clinic should be given work in the ward services. The admitting unit to the entire hospital should be in the outpatient clinic and should include the emergency unit. The unit record system should be used in all clinical cases, outpatient and inpatient, and should be filed in a record room situated in the outpatient clinic in close contiguity with the admitting unit. The follow-up, social service and consultation units should be located in each major therapeutic clinic. It is of great advantage to have the medical and surgical clinics in close contiguity and operating at the same hours of the day. Consultation units should be composed of medical and surgical men to study groups of cases. These men should agree on the therapy in the individual case, and should see these patients as follow-up cases whether they are treated medically, surgically or by any other form of therapy. These units should have working in them the attending physicians from the inpatient service of the hospital, the outpatient physician and surgeon interested in the group of cases under study, interns and medical students. Patients referred to the consultation units may come from any part of the clinic, may be sent in by any physician, or may be sent from any part of the ward service either as inpatients or as follow-up cases after leaving the ward service.

DISCUSSION

Dr. Willard C. Rappleye, New Haven, Conn.: In the advancement of medical science we come to the division of labor into two large groups, general practice and the specialty. The majority of the teachers in the schools of medicine today are specialists. Interlocking and interconsultation have got to be worked out in any scheme in which we have a division of labor. In medical education we are attempting to teach altogether too much. The student goes out without having in mind the relative proportion of things. When and how and to whom patients should be referred is a matter of intricate judgment, but it is the thing that the general practitioner will have to be able to recognize. Dr. Christian asked yesterday how effective we have been in producing physicians to take care of the public health of the community. One of the important keys in public health is the practitioner of medicine. There will come a division of labor that will throw on him as important responsibilities as he has ever had, but some amount of differentiation. We have also the problem of bringing adequate medical service to the community and to the individual at a reasonable cost. We have not yet been able to educate the community to the value of the proper kind of medical services.

---

[1] Meyerhof, O.: Beobachtungen über die Methylglyoxalase, Biochem. Ztschr. **159**: 432 (June) 1925.

Dr. Charles P. Emerson, Indianapolis: That there is a very definite lack in the way we physicians present our subject to the public is beyond dispute. The men who have spoken have all come to the same conclusion, a personal responsibility—very little division of labor, but a personal responsibility of the one man who will call to his aid those who he feels can help him solve the problem in the individual case. The more we group our men, the worse results we get. The responsibility rests with one single man and never can rest with a group. When we are ready so to train our students that they will study their cases thoroughly and not pass the responsibility to a dozen laboratories to save time, we shall be pretty near the solution of this problem. The more the laboratory work is done, the more accurately it is done, the better it is done, and the more his responsibilty increases in using the results of that laboratory in order to interpret those reports in terms of the patient.

Dr. Christopher G. Parnall, New York: We live in an era of change, if not of chaos, both in teaching and in medical practice. The pendulum, of course, swings the full swing to the two extremes; ultimately we find the middle ground. We have seen the passing of the family physician and we have seen the advocacy of group practice to make up for the deficiency of the family physician. Now we are seeing the failures of group practice. The old family physician, after all, is a good deal of a myth. In practically every community there was a certain proportion of practitioners who were able men, not because of their extreme skill in diagnosis, because as a matter of fact, if we tell the truth, they were about as often wrong in their diagnosis as they were right. Their success can be attributed to their empiric therapy. But, after all, they were successful largely through the fact that they came into intimate contact with patients and were able to study their idiosyncrasies and to give them common sense advice. The present type of physician who is being developed in our medical schools under present plans of medical education is vastly superior in all respects to the old time family physician. He is better material in the first place; better educated, better trained, and in the community he will occupy just as important a place as his predecessor. Methods of teaching and practice have got to be judged from two points of view: first, the good of the patient; second, the good of the student or the physician himself. Any method that does not work out to the advantage of the patient is obviously not a good one from the standpoint of the physician. Nothing can take the place of personal contact and personal responsibility between the physician and the patient. The individual physician in hospital practice, particularly, should be held responsible for treatment and for results. When he is held responsible for results, he is going to call consultation when it is necessary, and he will avoid consultation when it is unnecessary; incidentally, he will become self-reliant; he will teach self-reliance to the students and younger physicians associated with him.

Dr. I. D. Metzger, Pittsburgh: In the effort to make use of all the specialties and all the accessory investigations that might be helpful to the patient, we have come to the other extreme in that practically every staff man wants to use every department of the hospital in the care of his patient. There must be absolutely set some definite responsibility on some definite person for the conduct of the case throughout. The good general practitioner is not one who can do everything in medicine, but he is the one who is keenest in determining the needs of each case and the one who has the most efficient specialists at his command. He assumes the responsibility of the case, but nevertheless has these reserves whom he may command. The trouble is that most of the general practitioners feel that the case is lost to them as soon as the specialist gets through. The matter of health examination was brought up this morning. That is the most serious of all problems that the general practitioner has to deal with, and it is that we need to think of in our development of medical education. The matter of history getting is important. Sense of responsibility is the keynote to the physician. In nearly all the teaching hospitals there are men who see that there is correlation in the work. The general hospital does not have that kind of a person, and we have found that the best man to do that for us is a laboratory man. That man ought to be a diagnostician who can go about the hospital in the capacity of consultant.

THE DALLAS SESSION

Demonstrations of Periodic Health Examinations

Practical demonstrations of periodic examinations of apparently healthy persons will be given in Hall F, Automobile-Manufacturers' Building, Fair Park, at 8:30 a. m. and 4:30 p. m., April 20. These examinations will be conducted by Drs. D. W. Carter, Jr., George L. Carlisle, Homer Donald, John R. Lehman, J. Shirley Sweeney and Henry M. Winans. They are open to all members of the American Medical Association.

CORRECTION

Teachers of Diseases of Children

The Association of American Teachers of Diseases of Children will meet in Dallas, Tuesday, April 20, instead of April 19 as noted in The Journal last week.

CALIFORNIA

Diphtheria Control in San Jose.—The health department of San Jose has conducted an educational campaign against diphtheria for the last four years, and at least 3,000 children have been given toxin-antitoxin. The annual report of the city health department for 1925 shows that only forty cases of diphtheria occurred in the city, which is a great decrease over any other year since 1921. The incidence of other communicable diseases in San Jose maintained about the same average as it did in other cities in the state.

New Welfare Clinic.—Twenty-seven physicians of Santa Monica and vicinity have agreed to give part time free of charge to the work of the recently established Santa Monica Welfare Clinic in order to provide medical service for residents who are unable to pay. The clinic, it is reported, is sponsored by the Santa Monica Welfare Council and by the Women's Welfare Club and by the local branch of the Los Angeles County Medical Society. Dr. Howard Wilson Levengood has been elected chairman of the staff, and Dr. Louis E. Mahoney, secretary.

COLORADO

Typhoid Due to Raw Milk.—There were forty cases of typhoid in Denver from February 26 to March 14, most of which the city health department traced to milk from one dairy. It was found that of the forty patients, twenty-five used milk from one dairy and thirteen from another dairy; then, that the second dairy sold raw milk to the first dairy and was therefore at least indirectly involved in thirty-eight of the forty cases; one patient was the son of the owner of this dairy (although probably not the source); his father bought milk from a ranch whose employee had typhoid some years ago, and the manager himself had it in January. It is significant that milk sold by this ranch to another dairy which pasteurized its milk caused no typhoid along its route. Vigorous action was taken to prevent additional cases; an order was issued requiring all milk sold in Denver to be pasteurized; March 11, twenty-three dairymen attempted to deliver raw milk, and were summoned to court and fined $10 and costs each. Denver already had an ordinance providing that a dairyman selling raw milk must produce it all on his own place. Thus the dairy which apparently was responsible for the outbreak of typhoid had sold raw milk obtained from the ranch, regardless of the ordinance.

These units should have working in them the attending physicians from the inpatient service of the hospital, the outpatient physician and surgeon interested in the group of cases under study, interns and medical students. Patients referred to the consultation units may come from any part of the clinic, may be sent in by any physician, or may be sent from any part of the ward service either as inpatients or as follow-up cases after leaving the ward service.

DISCUSSION

Dr. Willard C. Rappleye, New Haven, Conn.: In the advancement of medical science we come to the division of labor into two large groups, general practice and the specialty. The majority of the teachers in the schools of medicine today are specialists. Interlocking and interconsultation have got to be worked out in any scheme in which we have a division of labor. In medical education we are attempting to teach altogether too much. The student goes out without having in mind the relative proportion of things. When and how and to whom patients should be referred is a matter of intricate judgment, but it is the thing that the general practitioner will have to be able to recognize. Dr. Christian asked yesterday how effective we have been in producing physicians to take care of the public health of the community. One of the important keys in public health is the practitioner of medicine. There will come a division of labor that will throw on him as important responsibilities as he has ever had, but some amount of differentiation. We have also the problem of bringing adequate medical service to the community and to the individual at a reasonable cost. We have not yet been able to educate the community to the value of the proper kind of medical services.

---

[1] Meyerhof, O.: Beobachtungen über die Methylglyoxalase, Biochem. Ztschr. **159**: 432 (June) 1925.

Dr. Charles P. Emerson, Indianapolis: That there is a very definite lack in the way we physicians present our subject to the public is beyond dispute. The men who have spoken have all come to the same conclusion, a personal responsibility—very little division of labor, but a personal responsibility of the one man who will call to his aid those who he feels can help him solve the problem in the individual case. The more we group our men, the worse results we get. The responsibility rests with one single man and never can rest with a group. When we are ready so to train our students that they will study their cases thoroughly and not pass the responsibility to a dozen laboratories to save time, we shall be pretty near the solution of this problem. The more the laboratory work is done, the more accurately it is done, the better it is done, and the more his responsibilty increases in using the results of that laboratory in order to interpret those reports in terms of the patient.

Dr. Christopher G. Parnall, New York: We live in an era of change, if not of chaos, both in teaching and in medical practice. The pendulum, of course, swings the full swing to the two extremes; ultimately we find the middle ground. We have seen the passing of the family physician and we have seen the advocacy of group practice to make up for the deficiency of the family physician. Now we are seeing the failures of group practice. The old family physician, after all, is a good deal of a myth. In practically every community there was a certain proportion of practitioners who were able men, not because of their extreme skill in diagnosis, because as a matter of fact, if we tell the truth, they were about as often wrong in their diagnosis as they were right. Their success can be attributed to their empiric therapy. But, after all, they were successful largely through the fact that they came into intimate contact with patients and were able to study their idiosyncrasies and to give them common sense advice. The present type of physician who is being developed in our medical schools under present plans of medical education is vastly superior in all respects to the old time family physician. He is better material in the first place; better educated, better trained, and in the community he will occupy just as important a place as his predecessor. Methods of teaching and practice have got to be judged from two points of view: first, the good of the patient; second, the good of the student or the physician himself. Any method that does not work out to the advantage of the patient is obviously not a good one from the standpoint of the physician. Nothing can take the place of personal contact and personal responsibility between the physician and the patient. The individual physician in hospital practice, particularly, should be held responsible for treatment and for results. When he is held responsible for results, he is going to call consultation when it is necessary, and he will avoid consultation when it is unnecessary; incidentally, he will become self-reliant; he will teach self-reliance to the students and younger physicians associated with him.

Dr. I. D. Metzger, Pittsburgh: In the effort to make use of all the specialties and all the accessory investigations that might be helpful to the patient, we have come to the other extreme in that practically every staff man wants to use every department of the hospital in the care of his patient. There must be absolutely set some definite responsibility on some definite person for the conduct of the case throughout. The good general practitioner is not one who can do everything in medicine, but he is the one who is keenest in determining the needs of each case and the one who has the most efficient specialists at his command. He assumes the responsibility of the case, but nevertheless has these reserves whom he may command. The trouble is that most of the general practitioners feel that the case is lost to them as soon as the specialist gets through. The matter of health examination was brought up this morning. That is the most serious of all problems that the general practitioner has to deal with, and it is that we need to think of in our development of medical education. The matter of history getting is important. Sense of responsibility is the keynote to the physician. In nearly all the teaching hospitals there are men who see that there is correlation in the work. The general hospital does not have that kind of a person, and we have found that the best man to do that for us is a laboratory man. That man ought to be a diagnostician who can go about the hospital in the capacity of consultant.

THE DALLAS SESSION

Demonstrations of Periodic Health Examinations

Practical demonstrations of periodic examinations of apparently healthy persons will be given in Hall F, Automobile-Manufacturers' Building, Fair Park, at 8:30 a. m. and 4:30 p. m., April 20. These examinations will be conducted by Drs. D. W. Carter, Jr., George L. Carlisle, Homer Donald, John R. Lehman, J. Shirley Sweeney and Henry M. Winans. They are open to all members of the American Medical Association.

CORRECTION

Teachers of Diseases of Children

The Association of American Teachers of Diseases of Children will meet in Dallas, Tuesday, April 20, instead of April 19 as noted in The Journal last week.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Diphtheria Control in San Jose.—The health department of San Jose has conducted an educational campaign against diphtheria for the last four years, and at least 3,000 children have been given toxin-antitoxin. The annual report of the city health department for 1925 shows that only forty cases of diphtheria occurred in the city, which is a great decrease over any other year since 1921. The incidence of other communicable diseases in San Jose maintained about the same average as it did in other cities in the state.

New Welfare Clinic.—Twenty-seven physicians of Santa Monica and vicinity have agreed to give part time free of charge to the work of the recently established Santa Monica Welfare Clinic in order to provide medical service for residents who are unable to pay. The clinic, it is reported, is sponsored by the Santa Monica Welfare Council and by the Women's Welfare Club and by the local branch of the Los Angeles County Medical Society. Dr. Howard Wilson Levengood has been elected chairman of the staff, and Dr. Louis E. Mahoney, secretary.

COLORADO

Typhoid Due to Raw Milk.—There were forty cases of typhoid in Denver from February 26 to March 14, most of which the city health department traced to milk from one dairy. It was found that of the forty patients, twenty-five used milk from one dairy and thirteen from another dairy; then, that the second dairy sold raw milk to the first dairy and was therefore at least indirectly involved in thirty-eight of the forty cases; one patient was the son of the owner of this dairy (although probably not the source); his father bought milk from a ranch whose employee had typhoid some years ago, and the manager himself had it in January. It is significant that milk sold by this ranch to another dairy which pasteurized its milk caused no typhoid along its route. Vigorous action was taken to prevent additional cases; an order was issued requiring all milk sold in Denver to be pasteurized; March 11, twenty-three dairymen attempted to deliver raw milk, and were summoned to court and fined $10 and costs each. Denver already had an ordinance providing that a dairyman selling raw milk must produce it all on his own place. Thus the dairy which apparently was responsible for the outbreak of typhoid had sold raw milk obtained from the ranch, regardless of the ordinance.

DISTRICT OF COLUMBIA

Dr. Hrdlicka Wins British Medal.—The Royal Anthropological Institute of Great Britain announces that the Huxley Memorial Medal for 1927 will be conferred on Dr.

Ales Hrdlicka, Washington, D. C., who will go to London in November of that year to deliver the Huxley lecture and to receive the medal. This is said to be the second time in twenty-six years that an American has received this award. Prof. William Z. Ripley, Ph.D., of Harvard University, having won the Huxley Medal in 1908. Dr. Hrdlicka has for years been curator of physical anthropology at the U. S. National Museum and has conducted anthropologic expeditions since 1898 in this and other countries. He is editor of the *American Journal of Physical Anthropology,* and the author of numerous books on anthropology and related subjects. One of his late expeditions to study the origin of man ended in October, 1925, with his return to this country from India, Ceylon, Java, Australia and South Africa.

ILLINOIS

Superintendent Appointed.—Dr. Duncan D. Monroe, formerly of Dawson Springs, Ky., has been appointed superintendent of the new $150,000 Madison County Tuberculosis Sanatorium, which will be formally opened, May 7.

Joint Meeting of Radiologists.—The Chicago Roentgen Society and the Central Illinois Radiological Society will hold a joint meeting at Champaign, May 18, during the annual meeting of the Illinois State Medical Society; physicians are invited to attend. Programs can be obtained by writing to Dr. Harold Swanberg, 731 Hampshire Street, Quincy.

Medical Movies.—The Adams County Medical Society, Quincy, held "medical movie night," April 12, when the film by Dr. Lewis G. Cole, New York, on "Gastric Motor Phenomena" was shown, also the film "How the Fires of the Body Are Fed," and several reels of various eye, ear, nose and throat operations on cadavers, through the courtesy of Drs. Walter Stevenson and Ray Mercer; another feature of the program was the report of the health survey of Adams County read by Dr. J. W. H. Pollard, now health officer of Evanston.

Personal.—Dr. Howard L. Metcalf, Springfield, has been appointed medical director of the Springfield Life Insurance Company, and Dr. John C. Eigenmann, Mechanicsburg, assistant medical director.——Dr. Thomas Parran, Jr., U. S. Public Health Service, who has been on duty with the Illinois Department of Health in connection with rural health work, has been relieved; he will go as a representative of this country to the International Health Conference in Denmark in May. A farewell dinner was tendered Dr. and Mrs. Parran at Springfield, March 27.——A farewell dinner was recently tendered Dr. Clarence T. Roome, Evanston, who recently resigned as health officer after fifteen years' service.

Chicago

Medical Care at Eucharistic Congress.—More than 400 Chicago physicians, and thousands of nurses and orderlies, according to *Hospital Progress,* will be available during the International Eucharistic Congress, June 20-24, to care for the health of the great number of persons that is expected to be present. There will be a temporary hospital at St. Mary's on the Lake at Mundelein, Ill., eight first aid stations near Grant Park Stadium in Chicago, where the principal ceremonies will be held, and other stations at the Municipal Pier and at the Coliseum.

Personal.—Dr. Harold Douglas Singer has resigned as medical director of the Illinois Society of Mental Hygiene ——Dr. Emmet Keating spoke on "Medical Policies and How They Affect You" at a luncheon given by the Women's Bureau of the Illinois Manufacturers' Association at the Hotel La Salle, April 10.——Mrs. Theodore B Sachs, superintendent, Chicago Tuberculosis Institute, is a member of a committee that met in New York, April 16, to prepare for the meeting of the International Union Against Tuberculosis and the National Tuberculosis Association in Washington, D. C., in October. Further information about these meetings can be obtained from the Chicago Tuberculosis Institute, 360 North Michigan Avenue.

Dinner to Dr. Davison.—Friends of Dr. Charles Davison, emeritus professor of surgery, University of Illinois College of Medicine, gave a dinner in his honor at the Congress Hotel, April 16, at which a bust of the guest of honor made by Lorado Taft was presented to the University of Illinois. A certificate was presented to Dr. Davison, appointing him attending surgeon emeritus at the Cook County Hospital, on which staff he has served continuously for thirty-two years. Among the speakers at the dinner were David Kinley, L.L.D., president of the University of Illinois; Dr. David J. Davis, dean of the college of medicine; Dr. Edward L. Heintz, an alumnus of the university and chairman of the committee in charge of the dinner; Lorado Taft; Anton J. Cermak, president, board of county commissioners, and Hon. William L. Abbott, ex-president of the board of trustees of the university.

INDIANA

Extramural Postgraduate Courses.—At the invitation of various county medical societies, the Indiana University School of Medicine is conducting postgraduate courses in surgery at Terre Haute, Seymour, Columbus and Madison. The courses are of eighteen hours each and the subjects have been previously agreed on by the societies and the medical school. It is pointed out in the *Journal of the Indiana State Medical Association* that the function of the school is not limited to training new physicians, but includes helping keep physicians abreast of the progress in medicine. The school at Indianapolis includes the medical school, the James Whitcomb Riley Hospital for Children and the Robert W. Long Hospital, which are organized as integral units of the school, the training school for nurses and the medical social service department. The last three years of the course are given in the city and the first year at Bloomington.

Society News.—The Tippecanoe County Medical Society and the Lafayette Dental Society held a joint meeting, recently, at Lafayette; a clinic was held at St. Elizabeth's Hospital and a banquet at the Lafayette Club. William H. G. Logan, M.D., D.D.S., dean, Chicago College of Dental Surgery, and former president of the American Dental Association, gave an address.——Every practicing physician in Rush County is an active member of the county medical society for 1926.——Dr. Henry S. Plummer, Mayo Clinic, Rochester, Minn., conducted a clinic before the Tippecanoe County Medical Society, St. Elizabeth's Hospital, March 11, on "Disorders of the Glands of Internal Secretion," and also addressed the society at a banquet at the Lafayette Club on "Endocrinology."——Dr. Martha Tracy, dean, Women's Medical College of Pennsylvania, Philadelphia, addressed the Muncie Academy of Medicine, Muncie, recently, on "Food and Efficiency."

IOWA

Notice to Tourists.—Information has been received advising tourists crossing Iowa to take advantage of the hard surface roads in the northern part of the state. The local newspapers have advised tourists from east and north to travel to Omaha by way of Sioux City; the roads in southern Iowa have not yet been placed in all-year-round travel condition.

Revocation of License Upheld.—The Iowa Supreme Court, in a decision handed down, March 9, upheld the state board of medical examiners in revoking the license of Dr. Clarence H. Hanson of Wright County, Sept. 24, 1924. Dr. Hanson was charged, it is reported, with intoxication and with two convictions in federal court for violation of the Harrison Narcotic Act.

Supreme Court Sustains Board of Health on Vaccination.—The Supreme Court of Iowa has sustained the decision of the lower court in the case of Carlyle M. Baehne, who, through his father, sued the local board of health and the school district to compel them to permit the boy to attend school without being vaccinated. The trial, which was held in January, 1925, concerned the question of issuing an injunction against the school board and the school district to set aside their order prohibiting unvaccinated pupils from attending school. Among other things, the judge said that "if there is evidence to warrant the school board in determining that there was an epidemic of smallpox, the discretion of the board cannot be interfered with by the court." The case was appealed and the supreme court held that the temporary exclusion of an unvaccinated child from school while an epidemic prevails does not present a case so compelling that the district court must issue a writ of injunction against the school and health authorities on petition of the parents.

MARYLAND

Expedition to Study Hookworm.—Plans have been completed for a research expedition to Central America under the leadership of William W. Cort, Ph.D., professor of helminthology, Johns Hopkins School of Hygiene and Public Health, for the purpose of improving control measures used to combat the hookworm. The expedition is part of a program of cooperation between the department of medical zoology at Johns Hopkins and the International Health Board, which has been carried on by Dr. Cort in various countries since 1921. The commission to Central America will be divided into two groups, one going to Panama, the other to Nicaragua, one group sailing from New Orleans about the first week in June, and consisting of Donald L. Augustine, S.D., assistant professor of helminthology, department of comparative pathology, Harvard University, Boston, and William A. Riley, Ph.D., professor of animal biology and head of the department, University of Minnesota, Minneapolis. The other group, which will leave New York for Nicaragua the latter part of May, will consist of Norman R. Stoll, Sc.D., associate in helminthology at Johns Hopkins; Harold Brown, assistant in helminthology at Johns Hopkins, and Maurice C. Hall, Ph.D., chief, zoological division, Bureau of Animal Industry, U. S. Department of Agriculture. Dr. Cort will divide his time between the two groups to coordinate the work.

MASSACHUSETTS

No Award of Boylston Prize.—The Boylston Prize Committee of the Harvard University Medical School, Boston, has voted not to award the Boylston Prize, as none of the essays submitted are worthy of the prize. By notifying the secretary, Dr. Henry A. Christian, Peter Bent Brigham Hospital, Boston, of the legend on the essay and the address, essayists may have their papers returned on request.

Breast Feeding Demonstration. — The Massachusetts Department of Health requests the cooperation of the medical profession in the establishment of breast feeding demonstrations in four cities and towns, which have been selected because the public health nursing is well organized in those communities. The object is to show that it is possible and desirable to increase the percentage of breast fed babies; the plan is to secure the consent of each physician to have their patients visited by a public health nurse who will see every mother two weeks after the birth. A "form" as a reminder of breast feeding will then be sent to the mother monthly, and will include a return form; every mother who fails to return the form or signifies thereon any difficulties in feeding will be visited by the nurse, and every mother will also be visited when the baby is 6 months of age.

MINNESOTA

State Medical Meeting.—The annual meeting of the Minnesota State Medical Association will be held at St. Paul, May 17-19. There will be a symposium on infantile paralysis by Drs. Carl C. Chatterton, St. Paul; Melvin S. Henderson, Rochester, and Frank W. Whitmore, St. Paul, and a symposium on cardiovascular renal disease by Drs. Hilding Berglund, Minneapolis; Leonard G. Rowntree, Rochester; Charles P. Emerson, dean, University of Indiana Medical College, Indianapolis, and Verne C. Hunt, Rochester. There will be clinics on diseases of the thorax by Drs. Willis S. Lemon and Stuart W. Harrington, Rochester, and on gastric diseases by Dr. Arnold Schwyzer, St. Paul. A novel feature will be the entertainment Wednesday evening given by members of the profession and their families, followed by dancing. The Monday evening meeting will be the usual medical "economics meeting" and the speakers will be Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, "Fads and Quacks"; Dr. Charles P. Emerson, Indianapolis, "Degenerative Diseases and Periodic Health Examinations," and Mr. Herbert R. Galt, managing editor of the *Dispatch and Pioneer Press.* The banquet Tuesday evening will be for physicians only, and among the speakers will be the mayor of St. Paul, the governor and Dr. Charles H. Mayo.

NEBRASKA

Hospital News.—The late Miss Belle Dewey, Omaha, gave about $50,000 toward establishing a ward or a building in connection with the Nebraska Methodist Hospital for the free treatment of poor women suffering from cancer.——The late Martin and Mary Ellen Duey, Chester, bequeathed $9,500 to the permanent endowment fund of the Methodist Hospital.

Fifty Years in Practice.—Dr. John A. Waggener, Humboldt, celebrated the completion of his fiftieth year in the practice of medicine, recently, and was presented with a gold watch and chain by friends at a dinner, and the following evening was guest of honor at the annual dinner of the chamber of commerce. Dr. Waggener has three sons who are physicians.

Society News.—Dr. Herman L. Kretschmer, associate clinical professor of surgery, Rush Medical College, Chicago, addressed the Lancaster County Medical Society, Lincoln, March 20, on "Infections of the Urinary Tract."——Dr. Edward C. Davidson of the Henry Ford Hospital, Detroit, addressed the Omaha-Douglas County Medical Society recently on "The Management of Burns."

NEW HAMPSHIRE

Physicians for Rural Communities.—In view of the publicity given to the scarcity of physicians in rural communities, the secretary of the New Hampshire state board of health announced, March 16, that the following physicans had been admitted to practice under reciprocity arrangements with other states:

Dr. Earl J. Chase, a graduate of Tufts, will locate at Bristol.

Dr. May Jane Rochelle, a graduate of Women's Medical College of Pennsylvania, Philadelphia, will locate near Bethlehem.

Dr. Earl W. Gayer, a graduate of Indiana University Medical College, Indinapolis, has located at Dover.

Dr. Demetrius N. Matsis, a graduate of Tufts, has located at Nashua.

Dr. Barbara Beattie, a graduate of Cornell, has located in Littleton.

NEW YORK

Assembly Approves Medical Bill.—The assembly passed the Webb-Loomis bill, April 6, by a vote of 95 to 33. The senate has not yet acted on the bill; among other things, it provides for the annual registration of physicians and for the appointment of a grievance committee of ten members by the board of regents to pass on complaints against licensed members of the medical profession, and holds fraud or deceit in practice, the conviction of crime or misdemeanor, habitual drunkenness, use of narcotics and deceptive advertising as grounds for revoking a physician's license.

Eye Lectures to School Teachers.—Under the auspices of the National Committee for the Prevention of Blindness and the New York Department of Education, Dr. Emily A. Pratt has, for three months, been lecturing in each of the normal schools of the state on the most progressive methods of preserving the sight of children. The lectures, which will continue until May 1, will be supplemented by demonstrations in public schools, conferences with school superintendents, and talks to parent-teacher associations. New school teachers will thus be able to carry out the laws requiring periodic examinations of the eyesight of children; they will have an understanding of the principles of good illumination and of ocular hygiene in general.

New York City

Professor Watson Comes to Columbia.—According to the *British Medical Journal,* Dr. Benjamin Philip Watson, professor of midwifery and diseases of women, University of Edinburgh, Scotland, has accepted the corresponding chair at Columbia University, and the directorship of the Sloane Hospital for Women.

Dr. Kosseff Appointed Medical Director.—Dr. Abraham Kosseff has resigned as physician in chief at the Sing Sing Prison, Ossining, to become medical director of the Beth Moses Hospital, Brooklyn. Dr. Kosseff graduated from Long Island College Hospital Medical School in 1915, and for the last nine years has been engaged in penal medical work as assistant physician at Sing Sing, then chief physician at Clinton Prison Hospital, Dannemora, and then as physician in chief at Sing Sing. He assumed his new duties March 1.

Baltimore Medical Club.—The spring meeting and banquet of the Baltimore Medical Club of New York, which is composed of graduates of Baltimore medical colleges who are practicing in this vicinity, will be held, April 29, at the Hotel Commodore. Dr. Arthur M. Shipley, professor of surgery at the University of Maryland School of Medicine, who will be the guest of honor, will make the address, and other entertainment will be provided. Tickets may be obtained from Dr. Louis Winfield Kohn, 425 Park Avenue, New York; six dollars.

Hospital News.—A benefit performance will be given at the Century Theatre, April 19, for the Hospital for Ruptured and Crippled Children; the opera "Pinafore" will be presented.——The Hospital Information Bureau of the United Hospital Fund has prepared a directory of convalescent homes of New York City and vicinity, one copy of which will be sent free to all charitable agencies on request and extra copies at 25 cents each.—"The Song of Flame" at the Forty-Fourth Street Theater will be given as a benefit for the Lincoln Hospital and Home, April 27.

French Society Buys Site. — The French Benevolent Society announced, March 5, the purchase of a plot of ground on West Thirtieth Street as a site for a new twelve-story hospital building to replace the present French Hospital at 450 West Thirty-Fourth Street. The French Hospital, which was established in 1881, erected the present building, the capacity of which is 105 beds, in 1904. It cared for 2,670 patients in 1925, about 45 per cent of whom received free treatment. Its policy is said to be nonsectarian, and its help is extended to persons of every nationality. A campaign for $2,000,000 for the new building was opened, March 22.

Courses for Sanitarians.—Columbia University again will offer this summer new courses for the training of sanitarians in epidemiology, industrial hygiene and factory inspection, and will also continue to give the courses that have been offered during the last two years. The period of instruction has been shortened from six weeks to two or three weeks and at the same time the daily sessions lengthened to two or four hours each, in order to serve the convenience of health workers. Application for these and all other courses in public health and preventive medicine should be made to the director of the summer session before June 1. A complete copy of the announcement of courses for the summer session may be obtained from the secretary of the university. The summer session will be from July 6 to August 13.

Personal.—Sir Arthur Newsholme, formerly principal medical officer of the London Local Government Board, is reported to have arrived in this country, April 5, to lecture on public health at leading institutions during the spring and summer.——Dr. Arthur Schueller, Vienna, Austria, addressed the New York Neurological Society, April 6, at the New York Academy of Medicine.——Dr. Aaron S. Maclaire has been promoted to adjunct professor in neurosurgery at the New York Polyclinic Hospital and Post-Graduate Medical School. ——Dr. Alfred M. Hellman gave a dinner at the City Club, April 3, in honor of R. L. Kahn, Ph.D., of the Michigan State Health Department, Lansing, which was attended by about fifty physicians; Dr. Kahn had been invited to demonstrate the Kahn Precipitation Test before the New York State Medical Society, which was in session at the Waldorf-Astoria Hotel.——Dr. Patrick J. Murray, for eight years chief surgeon of the police department, has been retired, and Dr. Daniel J. Donovan has been appointed to that position. Dr. Donovan has been a police surgeon for twenty-two years. ——Dr. Julius Lewis Amster has been appointed attending surgeon to the Jewish Memorial Hospital.

NORTH CAROLINA

Tarboro Dairy.—The city of Tarboro has just ended its ninth year of owning and operating a municipal dairy. Tarboro, a city of about 5,000 persons, buys milk from farmers at 12 cents a quart, and after pasteurization, distributes it to consumers at 17 cents a quart. There has been a decrease in the amount of milk-borne disease since Tarboro has been operating the dairy.

Sanitary Survey of Impounding Basin.—The state board of health started a survery, April 1, of the proposed impounding basin of the Tallahassee Power Company, the so-called aluminum trust. Engineers of the board will cooperate with the health departments of Davidson and Rowan counties in collecting all data that might bear on the relation of the proposed dam to public health. Our correspondent writes that the dam will make the largest artificial lake in the world, having, when completed, a shore line of more than 325 miles.

Personal.—Dr. Daniel R. Bryson has been reelected president of the chamber of commerce of Bryson City.——Dr. John W. MacConnell, Davidson, has been detailed as commanding officer of General Hospital no. 95, U. S. Army Reserve, located at Columbia.——Davidson College has conferred the degree of D.Sc. on Dr. Andrew J. Crowell of Charlotte, a member of the state board of health, and president of the Tri-State Medical Association (the Carolinas and Virginia).——The chamber of commerce of Charlotte has awarded a prize of $100 to Dr. Harvey P. Barret of that city, as being one of three citizens whose services to the city were outstanding during 1925.

OHIO

License Stolen.—The Ohio State Medical Board reports that the license of Dr. Michael Mitchell was recently stolen from his automobile near Utica, N. Y. Dr. Mitchell graduated from Western Reserve University Medical School in June, 1924, and was licensed to practice medicine and surgery in Ohio, July 8, 1924.

Society News.—Dr. Eugene F. McCampbell, dean, and professor of preventive medicine, Ohio State University College of Medicine, Columbus, addressed the Richmond County Medical Society, recently, on "The Postponement of Death."——Judge E. L. Porterfield, federal prohibition administrator, twelfth district, addressed the Columbus Academy of Medicine, recently, on prohibition laws affecting physicians.——Dr. Thomas J. Kirwin, New York, addressed the Academy of Medicine of Toledo and Lucas County, March 5.——Dr. Edward J. McCormick, president of the Academy of Medicine of Toledo and Lucas County, addressed the Wood County Medical Society, February 18, on "Gallbladder Surgery."—Drs. Louis A. Levison, Rosco G. Leland and Charles R. King, all of Toledo, gave a symposium on periodic health examinations before the Hancock County Medical Society February 10, at Findlay.——Dr. Carl Spohr, Ohio State University College of Medicine, Columbus, addressed the Clark County Medical Society at Springfield recently on "Blood Chemistry as an Aid in Diagnosis."—Dr. Floyd C. Hendrickson addressed the Stark County Medical Society at Canton, March 16, on "Studies in Abdominal Incisions."

OREGON

State Medical Election.—At the fifty-second annual meeting of the Oregon State Medical Society, Portland, April 1-3, Dr. Willis B. Morse, Salem, was elected president; Dr. Hugh S. Mount, Oregon City, president-elect; Drs. Leo B. Bouvy, La Grande, John W. Sifton, Hood River, and Alfred B. Peacock, Marshfield, vice presidents; Dr. John Earle Else, treasurer, and Dr. Frederick D. Stricker, Portland, secretary.

Juvenile Hospital.—The new juvenile hospital, which is being erected on the property of the Louise Home, east of Portland, under the auspices of the Pacific Protective Society, will open, June 1, with accommodations for fifty patients. There will be thirty single rooms; the last legislature appropriated $17,500; Multnomah County is to contribute $25,000, and the state outside the county is expected to raise $35,000.

Bridge Pays for Nurses' Home.—The county commissioners of Multonomah County recently received a check for more than $170,000 as a refund for money advanced by the county for constructing the interstate bridge between Oregon and Washington. The county commissioners are using the money to build the nurses' home on Marquam hill in Portland. Each person who crosses this bridge to the north helps to pay for the nurses' home.

PENNSYLVANIA

Mellon Lecture.—Dr. George N. Stewart, professor of experimental medicine, Western Reserve University School of Medicine, Cleveland, will deliver the Mellon Lecture of the Biological Society at the Carnegie Institute, Pittsburgh, April 30, on "Studies on the Adrenal Glands."

Expansion of Medical School.—The building program of the University of Pennsylvania comprises five units, one of which is the medical school. There has been set aside on the campus for the medical school the triangle formed by Hamilton Walk, on which the laboratories are now and at the apex of which is the zoology laboratory; another side of the triangle runs along Cleveland Avenue, and the other is a line running along the Philadelphia General Hospital. It will be necessary, eventually, to remove from this plot Botanical Hall and the gardens. The plan is to continue building medical laboratories along Hamilton Walk. Construction on the laboratory of anatomy and biochemistry, for which the General Education Board and the Rockefeller Foundation have given $500,000 and the university an equal amount, will begin soon; from time to time, other medical buildings will be erected in the remaining space within the triangle.

Philadelphia

Dinner to Dr. Stewart.—A testimonial dinner in honor of Dr Francis E. Stewart was given, March 23, by the faculty of the Philadelphia College of Pharmacy and Science and other friends, in recognition of his long service in the advancement of ethics in connection with the manufacture and distribution of medicinal products. Professor Charles H. LaWall of the faculty was toastmaster.

Campaign for River Crest.—A city-wide organization of volunteer workers will start a campaign, April 20, for funds to erect a building for the care of eighty children predisposed to tuberculosis. River Crest Preventorium, which now cares for twenty-five children, will be expanded with the funds raised. There will be an extensive exhibit at the Sesqui-Centennial, this summer, showing the progress made in tuberculosis work; among other things, the work done at River Crest will be demonstrated; it is the only place of its kind in the state.

Research Fellowships Available.—The Henry Phipps Institute offers fellowships to qualified applicants who desire to work in experimental pathology and bacteriology with especial reference to tuberculosis. They are open to physicians and doctors of philosophy or science who have majored in some fundamental medical science. Fellowships are also offered in clinical research. Fellows will receive from $1,500 to $2,500 in accordance with their experience. Applications should be sent to Dr. Eugene L. Opie, director of laboratories, Henry Phipps Institute, Seventh and Lombard streets, Philadelphia, with a brief statement of the applicant's education and experience in methods of research, and letters of reference.

Society News.—Dr. John A. McGlinn addressed the Obstetrical Society of Philadelphia, April 1, at the College of Physicians, on "The Failure of Radium in Non-Neoplastic Bleeding: Histologic Study of Removed Uteri."——Dr. Henry Leffman lectured at the Philadelphia College of Pharmacy and Science, April 1, on "The Wonders of the Microscope"; this was one of the popular science series of lectures for the public.——Dr. William H. Park, New York, addressed the College of Physicians, April 7, on "The Drive to Eliminate Diphtheria: The Use of Scarlet Fever Vaccine and Antitoxin."——Dr. Thomas Darlington, formerly health commissioner of New York City, spoke at the fifth annual meeting of the Philadelphia Heart Association, April 14, on "Preventing Heart Trouble."

TENNESSEE

Personal.—Dr. Samuel S. Moody, formerly of Louisville, Ky., has been made health officer of Weakey County. ——Dr. Lemuel C. Cox has been appointed city health officer of Kingsport.——Dr. Cummings Harris, Memphis, for many years epidemiologist to the city board of health, has resigned, and Dr. Samuel L. Wadley has been appointed to that position.——Dr. William D. Haggard, Nashville, President of the American Medical Association, was guest of honor at a banquet of the Knox County Medical Society, Knoxville, March 30; Dr. Haggard gave an address on "Goiter Surgery."

Dr. Klotz Goes to Cornell.—Dr. Walter C. Klotz, medical director of the National Home for Disabled Volunteer Soldiers, Johnson City, has resigned, effective, May 10, to accept a position on the faculty of Cornell University Medical School, N. Y. Dr. David Townsend, associate medical director, will succeed Dr. Klotz, and Dr. Edward B. Frisbee, now chief of the tuberculosis unit of the Pacific branch of the National Soldiers' Home at Sautelle, Calif., will become associate medical director. The new medical director, Dr. Townsend, is a graduate of Harvard Medical School and has been on duty at the Johnson City sanatorium since October, 1920.

Health at Nashville.—Telegraphic reports to the U. S. Department of Commerce from sixty-nine cities with a total population of 29,000,000, for the week ending March 20, shows that the highest mortality rate (27.2) was for Nashville, and that the mortality for the group of cities as a whole was 18.4. The mortality rate for Nashville for the corresponding week last year was 11.5 and for the group of cities, 15. A similar report from the department of commerce for the week ending March 27 also indicates that the highest mortality rate (32.9) among this group of cities was in Nashville, while for the group as a whole it was 19.4; for the group for the corresponding week last year the mortality rate was 14.8, and for Nashville, 15.7.

TEXAS

State Board Appointments.—The governor has appointed Dr. Joseph R. Frobese, San Antonio, a member of the state board of health to succeed Dr. Murff F. Bledsoe, Port Arthur, resigned; Dr. Ralph Bailey, Gatesville, was appointed to the board to succeed the late Dr. Edward L. Rose, Palestine.

Department for Periodic Examinations.—Baylor University College of Medicine, Dallas, announces that it will establish a department of periodic health examinations in the outdoor dispensary of the university for the examinations of apparently well persons, and that only persons entitled to free service will be admitted for examination. Beginning with the 1926-1927 session, all students admitted to the medical school will be required to submit to a complete health examination when admitted and annually until graduation; they will be required also to be vaccinated against smallpox when admitted, and will be urged to submit to vaccination against typhoid fever. This work will be done under the direction of the department of bacteriology, hygiene and preventive medicine, and comprehensive records will be kept on forms similar to those recommended by the American Medical Association for health examinations. The department of bacteriology, hygiene and preventive medicine, in cooperation with the state health department, will offer a short, intensive course this summer, probably in June, in public health, for which no fees will be charged and no certificates granted. During the first two weeks in June, the college and hospital will again offer diagnostic clinics in medicine and surgery and the specialties, and all reputable physicians are eligible to attend. There will be no fees charged and no certificates granted.

WASHINGTON

Society News.—Dr. Einar Hoff, Seattle, addressed the Puget Sound Academy of Ophthalmology and Otolaryngology, recently, on "Hay-Fever Caused by Pollen."——Dr. Henry Odland addressed the Skagit County Medical Society, recently, on "Diseases of the Skin," and Dr. Raymond L. Jeffery, on "Fractures."

Personal.—Dr. Harry V. Wurdemann, Seattle, has been commissioned a colonel in the Medical Reserve Corps, U. S. Army.——Dr. Charles E. Taylor, Tacoma, has been appointed superintendent of the Western State Hospital at Fort Steilacoom, to succeed Dr. David Livingstone.——Dr. William R. Leverton has resigned from U. S. Veterans' Hospital no. 59, it is reported, to assume charge of the physiotherapy department of the Tacoma General Hospital. ——Dr. Mitchell Langworthy, Spokane, has been appointed surgeon in chief of the Shriners' Hospital for Crippled Children, to succeed Dr. Charles F. Eikenbary, who is now in charge of the Children's Orthopedic Hospital in Seattle.—— Dr. Paul I. Carter, Tacoma, has been appointed chief medical officer of U. S. Veterans' Hospital no. 59.

GENERAL

Travelers Must Be Vaccinated.—An order was issued, March 27, by the U. S. Public Health Service, it is reported, requiring that all persons leaving the Pacific Coast for Alaska and Hawaii must be vaccinated against smallpox.

Oriental Journal of Diseases of Infants.—The first number of the new quarterly *Oriental Journal of Diseases of Infants* has been received. This new periodical is published by the Branch Office of the Oriental Medical Association, care of the Children's Clinic, Kyoto Imperial University; and is under the able editorship of Dr. T. Suzuki, who is assisted by a committee of specialists. The important and well illustrated articles appear in English, German and Japanese.

The Rights of Children.—Herbert Hoover, president of the American Health Association, in a letter urging the annual observance of May Day as child health day, said that the elemental rights of each child are:

> To be born well.
> To have a healthy childhood, and
> To reach maturity in the happiness that comes in its fulness only to those whose physical heritage has been safeguarded.
> With bodily health almost surely goes the natural selection of health associations, moral and spiritual as well as physical.
> Also with such health, and just as naturally, goes an aptitude to receive the right instruction easily; to be kind; to regard the rights of others; that is, to make good citizens.

Society News.—The American Association of Hospital Social Workers will hold its annual meeting at Cleveland, May 25-June 2, with headquarters at the Hotel Winton; information can be obtained from the secretary, Miss Lena R. Waters, 30 East Ontario Street, Chicago.——Among the speakers at the annual Conference of State and Provincial Health Authorities of North America, Atlantic City, May 21-22, will be Dr. Walter M. Dickie, California State Board of Health, "The Plague Situation in California"; Dr. Benjamin F. Royer, National Committee for the Prevention of Blindness, "The Need of Epidemiologic Research in Trachoma," and Dr. Samuel J. Crumbine, American Child Health Association, "A Summary of a Milk Survey in Twelve States."

High Cost of Nursing.—Two plans will be submitted as solutions of the high cost of nursing at the biennial convention of the National Nursing Organizations, Atlantic City, May 17-22. "Grouping nursing," which has already been introduced in some hospitals, provides one nurse to care for several patients. Thus, the patients are enabled to have the services of graduate nurses continuously at a moderate fee, and if not critically ill, have adequate attention; if critically ill, additional care is given; for example, a nurse cares for two patients in adjoining rooms with an intracommunicating passage way, and another nurse is on duty at night; a nurse on duty in a given suite remains indefinitely. By this plan, a nurse may not earn as much daily as a nurse on special duty, but she has steady employment and more time for recreation. "Hourly nursing" is for the care of patients outside the hospital. The nurse is engaged by the hour rather than by the day, and goes from patient to patient as the physician does. This plan is in practice in a number of cities by individual nurses, and in connection with the work of public health nursing organizations. It is said to give the patient graduate nursing at expense within his means, and

unloading 300 or 400 yards from marshy land, which was the breeding ground for mosquitoes. The lights of the ship were brighter than those on shore, and he was satisfied that there was a greater danger on board of being bitten than there was in the town, where certain preventive precautions were taken. The man had to attend to two furnaces and was bound to have an unshaded electric light in order to do his work. The heat and light of the boiler house attracted mosquitoes, while he had a smaller chance of avoiding their attacks than he would have had if he had not been at work. The judge held that the mosquito bite was an accident within the meaning of the compensation act and gave his award in favor of the applicant for $1,770 with costs.

Intracardiac Injection of Epinephrine in Apparent Death of New-Born

Reanimation of the heart by intracardiac injection of epinephrine is being more and more frequently reported by reason of the simplicity of the technic. Especially in syncope resulting from chloroform, the method has proved good. It was logical, therefore, to employ it in other cases of arrested heart beat. Garipuy and Mériel of Toulouse report a favorable result from intracardiac injection of epinephrine in a case of asphyxia in the new-born. In their case of an infant born apparently dead, without heart beats or pulsation of the umbilical cord, aspiration of mucus and artificial respiration had proved ineffectual. After five minutes an intracardiac injection of 1 cc. of a 1:1,000 solution of epinephrine was administered in the fifth left intercostal space midway between the median and the mammillary lines. Almost immediately the infant heaved a sigh and the heart began to beat. Artificial respiration was continued, and at the end of fifteen minutes normal respiration was established. The authors pointed out that, in infants, intracardiac injection is exceedingly simple. The lungs of the infant that has not yet breathed lie flat against the vertebral column. There is therefore no danger of injuring them in making a puncture between the median and the mammillary lines. After the lapse of from ten to fifteen minutes, all hope of resuscitation will be gone Therefore, no time should be lost, and, when ordinary maneuvers have failed, intracardiac injection of epinephrine should be given without delay. It will have every chance of being effectual if it is done within five or six minutes after the arrest of the heart beat. After the injection, artificial respiration and rhythmic traction of the tongue should be kept up. The injection of epinephrine is not supposed to supplant, only to supplement, these methods.

Death of Professor Moussous

French medicine has lost one of its most eminent pediatricians in the person of Professor Moussous of the University of Bordeaux, who died recently. Professor Moussous was born in 1857. He began his medical studies in Bordeaux and completed his medical course in Paris, where he served as hospital intern from 1882 to 1886. He later became hospital physician, then agrégé professor, and, in 1898, head professor at the University of Bordeaux, where he devoted all his
rgy to pediatrics. He was eminent as a clinician and his
ations are also of great value. Among his writings
olume of clinical lectures on the diseases of children,
ph on congenital affections of the heart, numerous
c handbook of children's diseases by Grancher
several articles in the *Archives des maladies*
hich he was one of the oldest and most
In spite of his manifold duties, he
d time for participation in movements
fare and uplift of childhood.

provides physicians with nurses for patients who do not require full-time nursing. "Hourly nursing" has been tried in connection with public health nursing organizations in Philadelphia, Milwaukee, Boston, Indianapolis, Omaha and other cities.

Foreign Physicians at Tuberculosis Meetings.—The biennial meeting of the International Union Against Tuberculosis will be held in Washington, D. C., September 30-October 2, and will be followed by the annual meeting of the National Tuberculosis Association which will also be held in Washington, October 4-7. The following foreign physicians have signified their intention of attending one or both of these meetings:

Prof. Vittorio Ascoli, Rome, Italy.
Dr. G. B. Roatta, Florence, Italy.
Prof. Gaetano Ronzoni, Milan, Italy.
Dr. Leon Bernard, Paris, France.
Dr. Jacques Parisot, Nancy, France.
Dr. Edouard Rist, Paris, France.
Col. S. Lyle Cummins, Cardiff, Wales.
Sir Robert W. Philip, Edinburgh, Scotland.
Prof. E. W. Archibald, Montreal, Canada.
Dr. Jabez H. Elliott, Toronto, Canada.
Dr. Charles D. Parfitt, Gravenhurst, Ontario, Canada.
Prof. Arthur Rousseau, Quebec, Canada.
Dr. David A. Stewart, Ninette, Manitoba, Canada.
Sir Henry Gauvain, London, England.
Dr. A. F. Miller, Kentville, Nova Scotia.
Prof. Francis Harbitz, Oslo, Norway.
Prof. Dr. Lydia Rabinowitsch-Kempner, Berlin, Germany.
Dr. Ernst Loewenstein, Vienna, Austria.
Dr. Fred. Neufeld, Berlin, Germany.
Dr. Ferdinand Sauerbruch, München, Germany.
Prof. Hugo Selter, Königsberg, Germany.
Dr. Jaquerod, Leysin, Switzerland.
Mlle. Helene Mugnier, Lyons, France.
Dr. A. Rollier, Leysin, Switzerland.
Dr. A. Stanley Griffith, London, England.
Dr. F. N. Kay Menzies, London, England.
Sir George Newman, London, England.
Prof. Friedrich Müller, Munich, Germany.

Reorganization of Indian Medical Service.—The U S. Department of the Interior announces a reorganization of the Indian Medical Service. Public health service methods will be installed in the handling of all medical, dental, health, sanitation and hospital activities of the bureau, under physicians detailed by the U. S. Public Health Service. Dr. Marshall C. Guthrie, U. S. Public Health Service, has been appointed chief medical director of the reorganized Indian Medical Service. Dr. Guthrie has had a long experience in public health work. He was stationed in New Orleans in 1905 during the epidemic of yellow fever, and has held various responsible positions in the public health service. The new plan is to establish four districts, each having a medical director in charge. The first district, with headquarters at Cloquet, Minn., will include Michigan, Wisconsin, Minnesota, Iowa, North and South Dakota, in which there is an Indian population of 64,419, ten Indian schools, ten agency hospitals, four sanatoriums, twenty-six agencies and many mission schools. The second district, with headquarters at Pendleton, Ore., includes Montana, Idaho, Washington, Oregon, Utah, Wyoming and northern California, and has an Indian population of 51,492, four Indian schools, eight agency hospitals, two sanatoriums, twenty-one agencies and many mission schools. The third district, with headquarters at Phoenix, Ariz., includes New Mexico, Nevada, Colorado, Arizona and southern California, and has 68,542 Indians, eleven schools, fourteen agency hospitals, six sanatoriums, thirty-six agencies and many mission schools. The fourth district, with headquarters at Muskogee, Okla., will include Kansas, Nebraska, Mississippi, North Carolina and Oklahoma. It has an Indian population of 64,419, seven Indian schools, three agency hospitals, three sanatoriums, sixteen agencies and many mission schools.

CANADA

Society News.—Among the guests who will participate in the program at the annual meeting of the Ontario Medical Association in London, Ontario, will be Dr. George E. de Schweinitz, Philadelphia, a past president of the American Medical Association, and Dr. Foster Kennedy, New York, who will contribute to the symposium on headache; Dr. Thomas McCrae, Philadelphia, will discuss nontuberculous pulmonary affections, and Dr. Leonard G. Rowntree, Mayo Clinic, Rochester, Minn., "Problems Connected with the Liver."——The Academy of Medicine of Toronto gave a dinner, February 2, to Dr. Donald C. Balfour, Rochester, Minn., who addressed the academy on "Peptic Ulcer."

Personal.—The New Brunswick government has appointed Dr. Walter W. White, St. John, on the Council of the College of Physicians and Surgeons of New Brunswick.——Dr. Henry A. McFarlen has been appointed president of the public school board of Winnipeg.——Dr. Oskar Klotz, professor of pathology and bacteriology of the University of Toronto Faculty of Medicine, delivered the Gordon Bell Memorial Lecture, Winnipeg, Manitoba, April 9; Dr. Klotz sails, May 1, for Lagos, West Africa, where, at the request of the Rockefeller Foundation, he will investigate yellow fever for six months.——Dr. Charles S. Morton, Halifax, N. S., has been elected director of the Ontario Equitable Life and Accident Insurance Company.——Dr. Archibald W. Hunter has resigned as pathologist to the Vancouver General Hospital, Vancouver.

FOREIGN

Spain to Hospitalize Lepers.—The Spanish government began a systematic campaign, according to the New York *Times*, March 19, to place all lepers in hospitals for treatment. The government intends to open well equipped leper hospitals with especially trained staffs in Andalusia, Santiago and the Canary Islands. There is a large hospital now in Valencia given over to the care of lepers. There are only about a thousand known lepers in the country; many others, it is feared, have not been discovered.

Society News.—The National Association for the Prevention of Tuberculosis will hold its twelfth annual conference, July 1-3, at Glasgow, Scotland, which will be open to all persons interested in tuberculosis on the payment of a fee of one guinea. The subjects for discussion are "The Actual Place and Function of the Tuberculosis Dispensary in the Tuberculosis Scheme" and "Provision for the Care of Nonpulmonary Forms of Tuberculosis." There will be a reception at the Municipal Building, July 1, by the lord provost of Glasgow, who will formally open the conference in the morning.

Personal.—The Fossati prize of the Istituto lombardi di scienze et lettere has been awarded to Prof. G. Aiello, on the staff of the Milan clinic for occupational diseases, for his work on "The Vegetative System in Fatigue."——Dr. Schenk, Poliklinik, Marburg, is in charge of the Sportarzt-Lehrgang, a course of graduate training in the medical aspect of sports, which is to be held there May 25 to June 5 this year. Our German exchanges add that attendance at the course entitles to the specialist title of Sportarzt—sport doctor.——Bohm, Kraus, Pirquet and others have been appointed a committee to study and introduce the BCG vaccine—if approved—into Austria in prevention of tuberculosis. Experiments on animals are under way.——Drs. Vialard and Darleguy of the French navy were awarded the navy prize for their "Epidemiologic and Clinical Study of a Meningococcus Epidemic."——Dr. Goepfert, 58, rue du Faubourg St-Jean, Nancy, is in charge of the fund for a medal to be presented to Prof. P. Haushalter on his retirement.——The director of the Assistance publique at Paris has announced the receipt from G. Blumenthal, New York, of a check for $60,000 for a new pavilion for ear and throat diseases at the Enfants-Malades Hospital.——Drs. Bernard, Duren and Trolli are the representatives of Belgium in the committee on tropical diseases sent by the League of Nations to western Africa. The members are to assemble at Dakar and hold the final conference at Sierra-Leone.

CORRECTION

Leora a Masculine Name.—In a collection of items pertaining to women physicians taken from the *Quarterly Bulletin* of the Medical Women's National Association, the name of Dr. Leora G. Bowers, Dayton, Ohio, president-elect of the Ohio State Medical Association, was included by mistake among the women physicians (The Journal, April 3, p. 1081).

Government Services

General Ireland Reappointed Surgeon General

The President has reappointed Major-Gen. Merritte W. Ireland as surgeon general of the U. S. Army and the nomination was confirmed by the Senate, April 8. General Ireland entered the military service in 1891; he served in the Spanish-American War, in the Philippine Insurrection and was chief surgeon of the American Expeditionary Forces in France in the World War until October, 1918, when he was appointed surgeon general of the army. He was awarded the Distinguished Service Medal for his services in the World War.

Foreign Letters

LONDON

(From Our Regular Correspondent)

March 20, 1926.

Osteopathy on the Defensive

Mr. E. T. Pheils, who describes himself as "vice president, British Osteopathic Association, chairman, Legislative Committee" has made an attempt to reply to the criticisms of osteopathy by Dr. Graham Little and Lord Dawson. He says that much of their matter against osteopaths has been accumulated from the "die-hards" of the American Medical Association. The recent debate in the house of commons is, he says, practically the same as that which has taken place in various United States legislatures previous to legislative protection. Now this statement is quite inaccurate, for the criticisms of osteopathy in this country, excepting the quotation of the American Medical Association's classification of colleges, have been quite independent. If they happen to coincide with anything said in America, it is simply a corroboration. "Well selected commissions," we are told, "invariably have reported that the osteopathic colleges compare quite favorably with the orthodox medical colleges." Then an Edinburgh graduate, also "D.O." of Kirksville, Mo., who therefore knows something about osteopathic colleges, is quoted as saying: "It is of interest to compare the average number of school hours in the five leading medical colleges in America (Cornell, Harvard, Jefferson, Northwestern University and Washington University) with the average number of school hours in the five leading osteopathic colleges (Kirksville, Chicago, Des Moines, Los Angeles and Philadelphia). Taking the subjects of anatomy, physiology, chemistry, pathology, bacteriology, diagnosis, practice of medicine, surgery, physiotherapy and the leading clinical subjects, the average number of school hours in the five leading medical colleges of America is 4,542, and the average number of school hours in the five leading osteopathic colleges is 4,953." As if "hours" were everything and the nature of the instruction and the instructors were not the main point. Then we are told that the majority of the members of the "British Osteopathic Association" are British-born men and women who have been compelled to go to the United States to qualify as osteopaths. "Because of the difficulty of the minister of health in recognizing or exercising any control over foreign diplomas, the British Osteopathic Association is founding a college of osteopathy in London. The British Osteopathic Association, including several registered medical men and Sir Herbert Barker, is competent to regulate the standards of this institution." Incidentally, it may be pointed out that Sir Herbert Barker is simply a "bonesetter" who never had anything to do with osteopathy before the present agitation for government recognition began, and therefore is not a competent "regulator," supposing that any "regulation" is to be taken seriously.

Report on Cancer of the Breast

A further report on cancer of the breast is published by the ministry of health and is described in a prefatory note by Sir George Newman, chief medical officer of the ministry, as "a useful and permanent addition to our knowledge of an obscure subject." A previous report prepared, like the present one, under the direction of Dr. Janet E. Lane Claypon, dealt with the results obtained after operation, and it was decided to follow this up by an investigation into the antecedent histories of 500 women who either were or had been victims of the disease. The inquiry was carried out in London and Glasgow. The new volume shows that only 15 per cent of the patients in hospitals had offered themselves for treatment at a stage at which real hope of prolonged relief or a possible cure by surgical treatment could be considered likely. "It has long been known," the report points out, "that unmarried women suffer from cancer of the breast at a higher rate than married ones." It is now proved that among married women those who are less fertile are at a disadvantage. The common belief that lactation at repeated pregnancies is a cause is shown to be baseless. Finally, this inquiry has confirmed and placed on a basis of statistical measurement the connection between the occurrence of cancer of the breast and a previous injury.

New Regulations for Insuring Clean Milk

A set of important regulations for securing cleanliness in the handling of milk is contained in the milk and dairies order, 1926, which has been drafted by the minister of health and is due to come into operation, July 1. Provision is made for the registration of all dairies and dairymen, and the duty of inspecting cattle in dairies is laid on every county and borough council. The order insists that cowsheds shall be properly lighted and ventilated, that they shall be kept "sweet and clean," and that they shall be whitewashed in May and October every year. It forbids the depositing of milk in any room used as a kitchen, scullery, living room or sleeping room, or in any place where it is likely to become infected, and requires that every person dealing with milk shall keep his clothing and person in a cleanly condition. The dairyman is required to report to the health officer any person in his household or the household of his employees who is suffering from an infectious disease, and health officers are given authority, when the supply or part of the supply of the dairy is suspected of being infected, to prohibit the sale of such milk for limited periods. Cattle in dairies must be kept clean, and the udders must be cleansed regularly before milking is begun. Cans and receptacles other than bottles, delivered to a dairyman, must be thorougly cleansed by him before he returns them. The penalties for offenses, as fixed by the milk and dairies (consolidation) act of 1915, are fines not exceeding $25 for the first offense, and not exceeding $250 for subsequent offenses; and not exceeding $10 a day in the case of a continuing offense.

Inspection of Imports

Regulations which it is proposed shall come into force, Jan. 1, 1927, lay on sanitary authorities the duty of inspecting imported milk, and forbid any person to import milk unless he is registered by the sanitary authority into whose district the milk is imported. If milk fails to reach a certain standard of cleanliness, the importer may be removed from the register; but appeal from the decision of the sanitary authority is provided. These regulations do not apply to condensed or dried milk.

Collective Investigation of the Status Lymphaticus

The exact part, if any, which status lymphaticus plays in the causation of sudden death is the subject of investigation by the Medical Research Council and the Pathological Society of Great Britain and Ireland. They are collecting information on the weights and measurements of the thymus gland on a large scale. The objects of the investigation are: (1) to establish, by means of a large series of weights and measurements, the standards of weight for age, and the proportion to body weight of the normal thymus at all ages; (2) to investigate closely the precise cause of death in persons dying suddenly from unexplained and trivial causes, when the only apparent abnormality is the presence of a large thymus.

In order to promote these objects, a committee of experts has been formed. Part of the scheme evolved by this committee is the appointment of a number of investigators in large centers to collect detailed records. But, in addition, the committee earnestly invites all other pathologists and physicians who perform necropsies to cooperate. The cases in which information is especially desired are: (*a*) cases of sudden death in apparently healthy persons of any age, including deaths from accident; (*b*) all cases of death in persons of 15 years or over who have an apparently glandular thymus. For this purpose, record cards have been prepared and will be sent on application for them.

Heavy Mortality from Motor Vehicles

During the period 1904-1923, the cancer mortality rate in England and Wales increased approximately 50 per cent, and the mortality arising from accidents caused by mechanically propelled vehicles by more than 1,000 per cent. During the same period, the mortality rate from all causes diminished by over 11 per cent. These comparisons were drawn by Major P. G. Edge in a paper read before the Royal Statistical Society on "The Growth of Mortality Due to Motor Vehicles in England and Wales, 1904-1923." "Cancer mortality," he said, "is fairly continuously pressed on the attention of the nation, but another cause of increasing mortality passes, not indeed without comment, even indignant comment, but without continuous public attention. Yet the deaths arising from street accidents mount up year by year. Each year the traffic problem presents increasing difficulties to be overcome by local administrative authorities; the effects of the increasing congestion on our streets and roads is reflected in the official returns of deaths caused by motor and other road vehicles." In 1904, motor traffic caused 171 deaths; in 1923, it caused 2,414. In spite of the fact that the general mortality in London was more than 30 per cent lower in 1923 than in 1904, deaths caused by motor vehicles showed an increase approaching 3,000 per cent. But American experience is much worse than ours. Indeed, the increased mortality has not only been much more rapid in the United States, but has attained a level more than double that of England and Wales. Higher mortality is also shown by American cities when compared with English ones. To insure the safety of foot passengers, Major Edge recommends: (1) a change in the law to permit (or insist on) local authorities to establish examinations of all drivers regarding physical fitness, technical skill and driving capability, before the issue of a license to drive; (2) compulsory insurance of the vehicle against mechanical defect (and perhaps against third-party risks).

Arsenic on Apples

The contamination of American apples with arsenic has been reported in previous letters. In another case a London fruiterer was fined $50 with $15 costs for selling 2 pounds (0.9 Kg.) of imported apples which contained 1/32 grain of arsenic per pound. The proceedings were the result of a complaint that people were ill after eating some of the apples. The local health officer declared that the dry wiping of apples for the removal of arsenic was of no use. "I have tried many methods," he said, "and I am of opinion that washing the apple is better than peeling it. But I do think that once the arsenic is sprayed on you cannot remove the whole of it in any way."

Indian Government's Opium Policy

The government of India is taking steps to give effect to the large sacrifices of revenue entailed by the new policy of eventual extinction of exports of opium, except for strictly medical purposes. For a long time, policy has been directed to preventing the use of Indian opium in the illicit trade in drugs. In 1915 the system of selling direct to importing governments was established and has been increasingly followed. Since 1923, no exports have been allowed save on certificates of the governments of the importing countries. Last year even certificated exports to Persia and Macao were prohibited. The signatories of the second Geneva protocol are to take measures to prevent within five years such smuggling as would seriously hinder the suppression of the use of opium in the Far East. The government of India interpreted the spirit of this obligation in the widest sense, as applying not only to actual smuggling from India but also to possible subsequent movements of opium legally exported. Accordingly, last year the government declared its intention to prohibit or restrict export even where foreign governments furnished import certificates, if there was evidence that opium in such foreign countries was finding its way into illicit trade. The further big step now taken goes beyond any requirement of the second Geneva protocol. The government has come to the conclusion that to avoid placing invidious restrictions on particular countries, and to carry out the policy of prevention to the utmost limit, exports to all countries shall be annually reduced and ultimately extinguished within a definite period. The policy requires the endorsement of the Indian legislature, but in the light of discussions which have been held from time to time in both chambers there is no reason to anticipate that it will be withheld. India has thus taken the lead in initiating the measure for which the proctocols provide, and by going far beyond her obligations is showing a determination to do all in her power to secure the improvement in the world opium situation which was looked for as a result of the Geneva conference.

Precautions to Be Observed in the Administration of Morphine and Heroin

A committee on morphine and heroin addiction, appointed by the ministry of health in September, 1924, was asked to advise as to the circumstances in which the supply of morphine and heroin to persons suffering from addiction to those drugs may be regarded as medically advisable, and as to the precautions which it is desirable that physicians prescribing morphine or heroin should adopt for the avoidance of abuse, and to suggest any administrative measures that seem expedient for securing observances of such precautions. It consisted mainly of experts: Sir Humphry Rolleston (chairman), Sir William Willcox, Dr. J. W. Bone, Dr. R. W. Branthwaite, Dr. G. M. Cullen, Prof. W. E. Dixon and Dr. John Fawcett. The report, which has just appeared, is of considerable importance. It states that morphine or heroin may be administered to addicts (*a*) when patients are under treatment by the gradual withdrawal method with a view to cure; (*b*) when it has been demonstrated, after a prolonged attempt at cure, that the use of the drug cannot be safely discontinued entirely, on account of the severity of the withdrawal symptoms produced; (*c*) when it has been similarly demonstrated that the patient, while capable of leading a useful and relatively normal life when a certain minimum dose is regularly administered, becomes incapable of this when the drug is entirely discontinued. In these cases the primary object of the treatment is the cure of the addiction, if practicable. The best hope lies in treatment in a suitable institution or nursing home. If the patient is unable to adopt this course or refuses, the physician must attempt cure by steady, judicious reduction of the dose. The patient should be seen frequently, be under sufficient control, and be in the care of a capable and reliable nurse. The physician should endeavor to gain his patient's confidence, and to induce him to adhere strictly to the course of treatment prescribed, especially as regards the amount of the drug of addiction which is taken. This last condition is particularly difficult to secure, as such patients are unreliable and frequently endeavor to obtain supplementary supplies of the drug. If, however, the physician finds that he cannot maintain the necessary control of the patient, he must consider whether he can properly continue indefinitely to bear the sole responsibility for the treatment. When the physician finds that he has lost control, or when the course of the case forces him to doubt whether administration of the drug can, in the best interests of the patient, be completely discontinued, he must consider whether he ought to remain in charge of the case and accept the responsibility of supplying or ordering indefinitely the drug in the minimum doses which seem necessary. The responsibility of making such a decision is obviously onerous, and both on this ground and also for his own protection, in view of the possible inquiries by the home office which such continuous administration may occasion, the physician will be well advised to obtain a second opinion. Severity of withdrawal symptoms on complete discontinuance after prolonged attempted cure, and inability of the patient to lead, without a minimum dose, a relatively normal life may appear to justify continuous administration of the drug indefinitely. The main object then must be to keep the supply of the drug within the limits of what is strictly necessary. The physician must see the patient sufficiently often for such observation as is necessary to justify the treatment. The opinion expressed by witnesses was to the effect that such patients should ordinarily be seen not less frequently than once a week. The amount of the drug supplied or ordered on one occasion should not be more than is sufficient to last until the next time the patient is to be seen. A larger supply would be justified only in exceptional cases; for example, on a sea voyage, when the patient was going away in circumstances in which he would not be able to obtain medical advice. In all other cases he should be advised to place himself under the care of another physician, who should be informed as to the nature of the case and the treatment pursued. Where the patient is suffering from organic disease for the treatment of which the drugs are necessary, the matter may be considered under two aspects: (*a*) cases in which the administration of morphine or heroin may be necessary for an indefinite period and in which the probability of a cure of the disease is remote (e. g., inoperable cancer); (*b*) cases in which administration of the drugs is called for in order to deal with conditions which, though due to organic disease, may be expected to be of more or less temporary duration (renal or biliary colic, etc.). In class *a*, the possibility of establishing a craving cannot be allowed to influence the administration of such doses of the drugs as are considered necessary for the adequate treatment of the organic disease; it will be in those rare cases only in which there is some prospect of partial or complete recovery from the disease that any attention can properly be given, during the course of treatment, to such measures as are likely to mitigate or avert the risk of subsequent persistence of any craving which may have been produced. In respect of class *b*, these measures become of paramount importance. They consist mainly in substitution, when possible, of other drugs for morphine and heroin, in close supervision by the physician of the amounts used and of the frequency with which they are administered, and in withdrawal of the drug as soon as possible.

Claim for a Mosquito Bite Under Compensation Act

An unusual compensation action was heard at the Manchester county court. A widow applied under the workmen's compensation act with regard to the death of her husband, who had been employed as a donkeyman on board a ship. He was bitten by a mosquito when the vessel was at Ghent and died thirteen days later, when the vessel arrived in the Manchester ship canal, from septicemia and pyemia following cellulitis. The judge said that the ship was unloading 300 or 400 yards from marshy land, which was the breeding ground for mosquitoes. The lights of the ship were brighter than those on shore, and he was satisfied that there was a greater danger on board of being bitten than there was in the town, where certain preventive precautions were taken. The man had to attend to two furnaces and was bound to have an unshaded electric light in order to do his work. The heat and light of the boiler house attracted mosquitoes, while he had a smaller chance of avoiding their attacks than he would have had if he had not been at work. The judge held that the mosquito bite was an accident within the meaning of the compensation act and gave his award in favor of the applicant for $1,770 with costs.

Intracardiac Injection of Epinephrine in Apparent Death of New-Born

Reanimation of the heart by intracardiac injection of epinephrine is being more and more frequently reported by reason of the simplicity of the technic. Especially in syncope resulting from chloroform, the method has proved good. It was logical, therefore, to employ it in other cases of arrested heart beat. Garipuy and Mériel of Toulouse report a favorable result from intracardiac injection of epinephrine in a case of asphyxia in the new-born. In their case of an infant born apparently dead, without heart beats or pulsation of the umbilical cord, aspiration of mucus and artificial respiration had proved ineffectual. After five minutes an intracardiac injection of 1 cc. of a 1:1,000 solution of epinephrine was administered in the fifth left intercostal space midway between the median and the mammillary lines. Almost immediately the infant heaved a sigh and the heart began to beat. Artificial respiration was continued, and at the end of fifteen minutes normal respiration was established. The authors pointed out that, in infants, intracardiac injection is exceedingly simple. The lungs of the infant that has not yet breathed lie flat against the vertebral column. There is therefore no danger of injuring them in making a puncture between the median and the mammillary lines. After the lapse of from ten to fifteen minutes, all hope of resuscitation will be gone Therefore, no time should be lost, and, when ordinary maneuvers have failed, intracardiac injection of epinephrine should be given without delay. It will have every chance of being effectual if it is done within five or six minutes after the arrest of the heart beat. After the injection, artificial respiration and rhythmic traction of the tongue should be kept up. The injection of epinephrine is not supposed to supplant, only to supplement, these methods.

Death of Professor Moussous

French medicine has lost one of its most eminent pediatricians in the person of Professor Moussous of the University of Bordeaux, who died recently. Professor Moussous was born in 1857. He began his medical studies in Bordeaux and completed his medical course in Paris, where he served as hospital intern from 1882 to 1886. He later became hospital physician, then agrégé professor, and, in 1898, head professor at the University of Bordeaux, where he devoted all his energy to pediatrics. He was eminent as a clinician and his publications are also of great value. Among his writings are a volume of clinical lectures on the diseases of children, a monograph on congenital affections of the heart, numerous articles in the handbook of children's diseases by Grancher and Comby, and several articles in the *Archives des maladies des enfants*, to which he was one of the oldest and most faithful contributors. In spite of his manifold duties, he always managed to find time for participation in movements looking toward the welfare and uplift of childhood.

Spirochetes in Relation to Pulmonary Gangrene

Bezançon and Etchegoin recently communicated to the Academy of Medicine the results of their microbiologic researches on pulmonary gangrene. They point out the rôle of spirochetes as well as that of nonsporulating anaerobes of the Veillon type, which Rist and Guillemot have shown to be of considerable importance. The existence of the spirochetes can be shown solely by the use of the following method: A specimen of sputum is shaken vigorously in a little physiologic sodium chloride solution and then placed in a water bath at a temperature of 29 C. for a quarter of an hour. The spirochetes are found on the surface of the liquid. Under these conditions, 285 tests were negative in various affections of the respiratory tract, but in seven cases out of eleven of pulmonary gangrene the authors found a peculiar spirochete which was quite different from the ordinary bacterial invaders of the mouth and which showed all the characteristics of the bronchial spirochete of Castellani. It was not *Spirochaeta vincenti,* and an attempt should not be made to attribute to fusospirillar symbiosis a rôle that has not been demonstrated. Various authors by their study of histobacteriologic preparations had shown that the central portion of the gangrenous foci contain Veillon anaerobes, *Bacillus fusiformis,* and certain rare spirochetes much altered, whereas the edges of the lesion revealed only an abundance of well preserved spirochetes. If one considers in this connection the extreme fragility of the spirochete, which is broken up in less than forty-five minutes in the sputum, one is led to believe that it plays a primary part in pulmonary gangrene when it is found to be present, and possibly also in the cases in which it has not been discovered in the sputum. It is the lung prepared by a spirochetal infection that is most likely to be attacked by anaerobes, the causative agents in putrid fermentation.

ITALY

The Italian Sanitary Mission in Yemen, Arabia

The governor of the Italian colony of Eritrea on the Red Sea, acting in accord with the central government at Rome, has complied with the request of the sultan of Yemen, in southwestern Arabia, to send him physicians, nurses and sanitary supplies. A mission has been dispatched to Sana, the capital of Yemen, where a hospital has been opened and is now in full operation. In spite of meager equipment and unfavorable surroundings, Drs. Mastrantonio and Pavone have performed numerous surgical operations. The purpose is to aid in the propagation of public health ideas and in the prophylaxis of infectious diseases.

Death of Prof. Camillo Golgi

Senator Camillo Golgi, the professor of general pathology, to whom we are indebted for the histology of the nervous system, has died at the age of 86. He discovered in 1874 his method of chrome-silver impregnation. Applying the method to the study of the brain and the spinal cord, Golgi was able to follow the ramifications of the processes of the nerve cells, to note the course of the individual fibers, to study the processes of the cells of the neuroglia, and to differentiate the two types of nerve cells (I and II) which are named after him Golgi's cells. He was one of the first to formulate the neuron theory. Also his studies on malaria led to many fundamental discoveries, such as the asexual cycle of the malarial parasite; the connection between sporulation of the parasite and the febrile attack, and the description, in addition to the evolutional forms, of the degenerative forms of the parasites. Golgi received, while still a young man, calls to other, larger institutions; but, having become well known for his researches at the University of Pavia, he never wanted to leave. He was a member of the Accademia dei lincei and of many other important Italian and foreign scientific academies. He had recently been the recipient of a Nobel prize.

The Academy of Italy

By a recent decree, the Accademia d'Italia has been created. The headquarters of the new society will be in Rome in a palace to be donated by the government. The object of the society is to promote and coordinate Italian intellectual movements in science, literature and art, preserving their pure national character and facilitating their expansion in foreign lands. The membership will be limited to sixty appointed by royal decree and subject to the approval of the society. The king will appoint for the present only thirty charter members. The society will have no corresponding members, either Italian or foreign.

An Italian Precursor of Pasteur

At a conference held, February 2, at the Scuola di sanita militare, Senator Alessandro Lustig, professor of general pathology, Florence, depicted a great Italian scientist of the last century who has of late years been almost forgotten. The great scholar was Agostino Bassi, who, born near Lodi in 1773, was graduated in medicine by the University of Pavia. He is entitled to be called a precursor of Louis Pasteur. Studying a serious disease of the silkworm (*calcino,* so called), Bassi established the contagious nature of the malady and demonstrated that it is transmitted from diseased to healthy worms through inoculation with organic material; through contact with animals that have died from the disease, or through contaminated air. For all his assertions, Bassi furnished proof by means of entirely new and ingenious experiments. Also domestic animals, human hands, foods and insects (flies and fleas) were designated by Bassi as possible vehicles of the disease. Bassi declared that *calcino* was "caused and transmitted by a being endowed with organization and life." He established that the morbigenous agent grows only on silkworms. Bassi was the first to establish that prophylaxis of infectious diseases may be accomplished by means of disinfection, and as disinfectants he recommended the same agents that are used today (dry and moist heat, mineral acids, lime, soda and potassium). His work on *calcino,* the fruit of thirty years of study, was published, 1835-1839. Other important researches of Bassi were on the etiology and prophylaxis of pellagra, published in 1846. He attributed the disease from the start to the use of spoiled or fermented maize, and advanced the opinion that fermentation of the grain is due to organisms of a vegetable nature, as was later demonstrated by Pasteur. He recommended, therefore, inoculation with dried extracts of maize, in the prophylaxis of pellagra. In 1852, Bassi asserted that "all contagious diseases are produced by parasitic microorganisms, vegetable or animal." It is curious that it was in connection with the study of another infectious disease of the silkworm (*pebrina*) that Pasteur began, in 1863, his discoveries in relation to infections. In honor of Agostino Bassi, a national committee has recently been appointed which will republish the works of the scientist of Lodi.

Organization of the Aviation Sanitary Service

By a recent government decree, the details of the aviation sanitary service have been established. In the department of aeronautics (recently constituted), there will be a central bureau of sanitation, which will have under its control a central committee for the study of aviation with respect to sanitation, the medicolegal institutes, the regional sanitary bureaus, the infirmaries and the first-aid stations in the aeronautic camps, schools and societies.

Sterilization of the Unfit

The Société d'anthropologie of Brussels has taken up the question of sterilization of abnormal subjects, from the anthropologic point of view. There is at present evidence of an augmentation in the number and of a retrogradation in the character of the sexual misdemeanors committed. Vervaeck discussed all phases of the question and referred to the action that had been taken in foreign countries. In Scandinavia, laws have been passed prohibiting marriage in the presence of certain mental affections, such as constitutional epilepsy, leprosy and infectious venereal diseases. In such cases the physician is required to notify the authorities. However, serious difficulties lie in the way of prophylactic sterilization. The diagnosis of hereditary diseases and the prognosis of hereditary defects is difficult. Again, from the moral aspect, such a measure is repugnant to our feelings and sterilization would not be acceptable at all except with the consent of the subject or of his family. The author concludes that the crusade against degeneracy must never be cruel or unjust, or impose mutilations that may entail disagreeable consequences from the physical or mental standpoint; for the experiences collected thus far are by no means conclusive. To treat abnormal subjects, it is much better to combat degeneracy at its origin: alcoholism, syphilis, etc. Furthermore, the sterilization of abnormal subjects does not avert their social danger, and it will always be difficult to adopt a measure which presents so many obstacles of all kinds and which is so directly in conflict with our usual public policy and customs.

Cancer in Relation to Industrial Accidents

Before the Société belge de médecine et de chirurgie des accidents du travail, Dr. Brohée discussed recently the problem of the traumatic etiology of cancer, and, more particularly, of cancer of the stomach. Trauma does not provoke cancer directly. It is not the sole cause, but it is one of the causes. From the medicolegal point of view, certain cancers may be recognized as the result of industrial accidents. Legal responsibility must take account of these criteria: Traumatism may be considered the principal cause if the cancer develops not less than one month nor more than three years after the accident in question, or in case of an aggravation resulting in death in a shorter time than would otherwise have occurred. Traumatism may be considered as a partial cause if the cancer is slightly aggravated. Traumatism must be considered as of no influence if it merely leads to the discovery of a preexisting cancer without affecting its evolution. While a gastric cancer cannot be caused directly by traumatism, an ulcer that develops as the result of a traumatic lesion of the gastric mucosa may be considered as a traumatic ulcer. A cancer developing on the site of an injury might, through an inaccurate use of language, be termed a traumatic cancer of the stomach. In such a case it will always be difficult to furnish definite proof of what is the true condition, for the past history is not sufficient.

Intravenous Injections of Quinine

Addressing successively the Cercle médical of Léopoldville and the Société belge de médecine tropicale, Drs. Seidelin and Fidao entered a plea in favor of intravenous injections of quinine. Seidelin advocates concentrated solutions, and it is his experience that accidents are insignificant. He does not confine the method to emergency cases, for he holds that intravenous injections sometimes produce a more energetic action than buccal administration. The latter method will, however, remain the method of choice in daily practice. Fidao has found that doses of 0.5 Gm., if given intravenously, will have as much effect as doses of from 1.5 to 2 Gm. by mouth, for he does not believe in the more rapid elimination of the drug when given intravenously. He has examined urines voided every two hours after the intravenous injection of 0 5 Gm. of quinine in sixteen patients. When the patient has urinated a short time before the injection, one finds quinine in the urine during the first quarter of an hour. The maximal elimination takes place from the second to the fourth hour, but even fourteen hours later the reaction is still appreciable. Fidao affirms that, in grave cases, intravenous injection is the preferable method. In cases of moderate severity its efficacy is equal to that of buccal administration, but its use is restrained by the fear of local accidents. In chronic malaria, when, in spite of continued administration of quinine by mouth, the patient retains parasites and shows a bad general condition, four or five intravenous injections (say, 2 Gm. of quinine in four hours) will free the patient from parasites and will improve his general condition. In chronic cases, however, the objection to local reactions has more weight because they are more frequent than in acute cases, and then, again, the patients concerned are working regularly every day and are thus more discommoded by them.

Acidosis in Relation to Polycythemia

To the clinical society of the hospitals of Brussels, Dr. Schuermans presented recently a communication which appears to throw new light on the etiology of polycythemia, and especially of true erythremia or Vaquez' disease and of emphysematous and cardiac polycythemia.

The daily injection of heavy doses of sodium bicarbonate caused an almost 50 per cent decrease in the number of red corpuscles. The leukocyte count is not affected. The percentage of hemoglobin remains very high. However, the subjective symptoms improve. With the cessation of the ingestion of bicarbonate, the erythremia returns to its former status. The author endeavors to explain the therapeutic result by considering polycythemia as dependent on acidosis of the blood plasma. Sodium bicarbonate, by neutralizing the plasma, may cause the disappearance of the polycythemia.

New Findings in Epilepsy

Addressing the Société belge de biologie, Dr. Dautrebande presented the results of his researches on the acid-base equilibrium of the blood in epilepsy. He believes that there exists in epilepsy an abnormal product of metabolism of alkaline reaction which combines with difficulty in vivo with carbon dioxide.

Death of Professor Morelle

The death of Dr. Morelle, professor of dermatology at the University of Louvain, has been announced. Professor Morelle was called in 1919 to the medical faculty of the university to assume the chair of dermatology. Among his best known works are his treatises on face grafts, treatment of lupus and skin cancers.

Law Pertaining to Sugar and Saccharin

Belgium has a law for the protection of the sugar industry. The law forbids the importation, the manufacture, the transportation, the keeping on hand and the sale of saccharin and like products. Owing to that fact, no dentifrices that contain saccharin even in minute quantities may be imported into Belgium. Technicians find in saccharin a valuable antiseptic in mouth hygiene. Several attempts have been made to induce the government so to change the interpretation of the law that tooth pastes, creams and lotions may be regarded as medical products, which would thus no longer come under the application of the law. Heretofore, dentifrices have been classed under the same head as perfumery.

Roentgenography of the Biliary Tract

The presentation of a number of cases of roentgenography of the gallbladder before the Société belge de radiologie has reawakened interest in questions of interpretation and of technic. In general, the authors would not accept the finding, which appeared to them too radical, that every gallbladder that does not become visible in the roentgenogram is in a pathologic condition. Tetrabromphenolphthalein appears more dangerous than tetraiodophenolphthalein, and intravenous injection (of the sodium salts) should usually be replaced by the ingestion of keratinized capsules.

GENEVA

(From Our Regular Correspondent)

March 25, 1926.

Two Cases of Insuloma

To date there have been reported thirteen cases of insuloma, or langerhansian adenoma. Dr. H. Schneider, working in the pathologic institute of the University of Lausanne, has recently published a thesis on two more cases, making fifteen in all. One of these was observed at Lausanne; the other is from the institute of pathology of the University of Geneva. These adenomas develop indifferently in the head, body or tail of the pancreas. Their diameter varies from a few millimeters to a few centimeters. One of the adenomas studied by Dr. Schneider is the largest recorded, and measured 5.5 by 4 cm. Of the fifteen recorded cases, all but two were found at necropsy of elderly subjects whose death was due, with one exception, to arteriosclerosis. One of Dr. Schneider's cases is the oldest so far reported, the subject being a man, aged 84. In this case a congenital origin of the tumor was suspected. Besides the pancreatic growth, there were adenomatous nuclei in the prostate and numerous cysts in the kidneys. Although the neoplastic nature of the latter is still a question, it is admitted that renal and hepatic cysts often encountered in the same subject develop from an embryonal disturbance. This subject, furthermore, presented a dermatomyoma of the right big toe.

To explain the genesis of pancreatic growths is difficult. The frequency of insular lesions in diabetes mellitus is nevertheless unquestioned. Schneider points out that it may be well to study the relations between insulomas and disturbances of sugar metabolism. In the fifteen cases so far recorded, two of the patients were diabetic. Schneider does not believe that these growths cause diabetes. It is to be hoped that in future instances of insuloma, detailed examination of the entire pancreas—especially by Heiberg's methods—will be undertaken to throw more light on this problem.

Two Cases of Cystic Disease of the Intestine

Dr. Albert Reverdin of Geneva has recently reported two cases of cystic disease of the intestine, a rare affection whose exact etiology is still unknown. The first case was diagnosed at laparotomy, and the specimens were examined immediately after removal. Microscopically, the cysts were of spherical lamellae bounded by fibro-adipose tissue and occasionally lined with a layer of flattened cells. The endothelium of the submucous lymphatic vessels, in which the gas was contained, showed inflammatory reaction. No bacteria were detected in the sections. By roentgen-ray examination, Reverdin diagnosed preoperatively the second case as cystic intestinal pneumatosis. The film revealed a clear area streaked by dark arches which did not resemble valves. The image was located on the right between the diaphragm and the liver, and on the left between the diaphragm and the gastric dome. Reverdin points out that some gastro-intestinal affection has coexisted in 75 per cent of the reported cases. The contents of the cysts are composed of gas containing 10 per cent of carbon dioxide and 90 per cent of nitrogen. Bacterial origin has as yet not been shown to exist.

Operative Mortality in Simple Hyperthyroidism

The operative mortality in simple goiter is now very low. De Quervain of Berne, in his recent statistics of 2,220 cases of simple goiter, found a mortality of 0.86 per cent. Of 1,682 patients under 40 years, de Quervain's mortality was 0.06 per cent, while of 316 operations on patients in the fifth decade there were three deaths, or about 1 per cent. In the sixth decade 145 patients gave a mortality (six cases) of 4.1 per cent, while in the seventh decade there were forty-six operations with seven deaths (nearly 20 per cent). In the eighth and ninth decades there were eight cases with two deaths, or 25 per cent. These figures show that the danger appears at the time of life when the cardiovascular and renal systems commence to show the changes of advancing life. It is then that operative shock and pulmonary postoperative complications—bronchitis and pneumonia—are fatal.

Subcutaneous Tumors from Injection of Drugs

Dr. J. L. Nicod of Lausanne has recorded two new cases of subcutaneous tumors, the result of subcutaneous injection of drugs. In one of these cases the nodules, which were multiple and of various sizes, were the result of injections of camphorated oil and quinine given eleven years previously. The second patient was a woman, aged 24, who eight months previously had been given injections of quinine in the buttocks. In both cases the process was a granuloma developing in the areas of the injections of quinine and camphorated oil given many years previously. The watery solution or oil injected at once produced a cyst which did not become absorbed and, acting like a foreign body, set up an inflammatory reaction around it. In view of the extensive use of camphorated oil injections, these morbid processes are rare. The cases so far reported have occurred in weak patients with some serious infective process and whose power of subcutaneous absorption has been injured, perhaps by lesions of the terminal vascular branches. In such patients, Nicod advises the venous route.

New Gastrostomy Technic

In the operation of gastrostomy, Dr. Cornioley of Geneva makes a rectangular cutaneous epigastric flap with the pedicle above. The long axis of the flap runs from right superior to left inferior and measures from 6 to 8 cm., the breadth at the pedicle being 4 cm. and at the free border, 5 cm. The epidermis is next removed with a sharp curet over an area of 15 cm., completely exposing the dermis. The flap is then rolled up into a tube, and the edges are sutured together. The abdominal cavity is opened through the left rectus muscle. A cone of the gastric wall is drawn out through the opening in the muscle and sutured to the parietal peritoneum. The apex of the gastric cone is then cut off to make a circular opening in the stomach. With four V-shaped silk sutures, the gastric cone is drawn into the lower portion of the cutaneous tube, sutured in place, and approximation is completed by a circular suture uniting the cutaneous tube and stomach. A few catgut sutures close the opening in the rectus muscle, and the entire field of operation is then covered over by autoplasty with two cutaneous flaps. The sound is left in situ for a fortnight, after which it is introduced only for feeding.

BERLIN

(From Our Regular Correspondent)

March 6, 1926.

The Hygienic Aspects of Sleep

In an article in the *Deutsche medizinische Wochenschrift*, Prof. I. H. Schultz, psychotherapeutist of Berlin, discusses psychotherapy in insomnia. The physician must get the hypochondriac patient to realize that he does not spend "absolutely sleepless nights." Then, again, the patient must be taught that it is possible to learn to sleep. He must be impressed with the idea that the length of hours is not so important as the quality of the sleep; furthermore, he should know that loss of sleep can be compensated for by increased food intake and other measures. The patient must be urged to spend the evening in such a manner that he will be in a calm state of mind on retiring. One should accustom oneself to noises so as to be able to fall asleep, and to continue to sleep, in spite of them. According to Schultz, hypnotism should be resorted to only in very severe cases of insomnia, but then the results are good.

Dress as an Expression of Sexual Feeling

In a lecture with lantern slides, recently delivered by Dr. Magnus-Hirschfeld, the well known investigator on sexual subjects, in the Institut für Sexualwissenschaften, he took as his theme the old controversial question, "Why Do We Wear Clothes?" He discussed the various theories that have been presented—"for protection," "to cover our nakedness," "as adornments to our person," "for purposes of allurement"—and then gave his conviction that the habit of dress sprang from an instinctive desire to express sexual aptitudes. Possibly we wear clothes at all because we need protection, while the kind of clothes we wear is decided by our instinctive impulses; especially, the desire for erotic allurement. In other words, *"Wir ziehen uns an, um andere anzuziehen,"* which may be freely rendered: We dress according to fashion, to fashion others' desires. Hirschfeld remarked that persons who had an antipathy for fancy costumes were suffering from blocked expression of instinctive impulses. Others, however, find satisfaction in hiding their ages at masquerade balls, or their stations at dances in the servants' quarters, or in forgetting for the moment that they belong to a certain historical period by donning the costume of a previous age. Those who are not satisfied unless they can wear the clothes of the opposite sex, often, while not homosexual, find in this disguise satisfaction of their instinctive impulses. Hirschfeld thinks that the present coiffure of women is controlled by such factors or impulses. The masculinization process, which is going on in women, had as its first expression bobbed hair. A photograph dating back twenty years and representing a female figure with bobbed hair, standing collar and black divided skirt at that time looked ridiculous, but now we inspect it quite unmoved. However, we must not forget that styles have only a relative significance. In this connection, the speaker conjured up the picture of a German bridal couple around 1500. The young man has long, flowing hair, an overgarment cut low in the neck, and coquettish puffed sleeves, while the bride has short locks and wears a simple, tight-fitting dress. So marked are the changing conceptions as to what constitutes "masculine" and "feminine" in dress. Nevertheless, Dr. Hirschfeld prophesied that the "boyish bob" was likely to persist for some time. It is in keeping with the demands of the time, which have likewise caused the Chinese to sacrifice their queues, and men, for the most part, their full beards.

Extreme types of transvestites endeavor to transform their bodies to make them resemble more the opposite sex: "Hapless creatures whose souls have been condemned by fate to spend their earthly days in cells their tastes berate." The presentation before the assemblage of a genuine transvestite was the climax of the lecture; a man who insists on comporting himself like a woman, calls himself "Dora," and even in his gait and his speech betrays almost superfeminine coquetry. The psyche of these mysterious persons is exceedingly puzzling. For instance, the mere recollection of the period in "Dora's" life in which the male characters were dominant brings a blush to "her" face.

Marriages

Erasmus H. Evans Taylor, Morganton, N. C., to Miss Julia Barber of New York, March 23.

Abraham Antweil, Fort Worth, Texas, to Miss Frieda Belle Maier of Lockhart, February 7.

William B. Clendenning to Miss Anna Marie Schellhase, both of Waynesburg, Pa., March 31.

Deaths

Edward Aloysius Weiss ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1900; assistant professor of gynecology at his alma mater; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the Associated Anesthetists of the United States and Canada; on the staffs of the Roselia Maternity, Magee, Presbyterian and Mercy hospitals and chief of staff of St. Paul's Roman Catholic Orphan Asylum; served during the World War, aged 48; died, March 24, at Honolulu, Hawaii, following an infection of the hand, contracted while performing an operation.

John Michael Stadter, Wilmington, Del.; Atlantic Medical College, Baltimore, 1908; member of the Medical Society of Delaware; on the staffs of the Physicians' and Surgeons' and the Delaware hospitals, and formerly on the staff of the Wycoff Heights Hospital, Brooklyn, aged 42; died recently, of influenza

Arthur Sherwood Corwin ⊕ Rye, N. Y.; Medical Department of the University of the City of New York, 1898; past president of the Westmoreland County Medical Society; on the staffs of the Grasslands Hospital, Valhalla, and the United Hospital, Portchester; aged 54; died, March 24, of pneumonia.

George Lewis Collins, Providence, R. I.; Medical School of Harvard University, Boston, 1879; member of the Rhode Island Medical Society; formerly on the staffs of the Rhode Island, Providence Lying-In and St. Joseph's hospitals; aged 74; died, April 1, of angina pectoris.

Charles Franklin Loeding, Portland, Ore.; University of Oregon Medical School, Portland, 1912; member of the Oregon State Medical Society; aged 43; died, March 21, at the Portland Sanitarium, of injuries received when a tractor toppled over on him.

Joseph C. Lincoln, Bowling Green, Ohio; Rush Medical College, Chicago, 1871; Civil War veteran; formerly probate judge; at one time a druggist, member of the board of education, and councilman; aged 81; died, March 24, of injuries received in a fall.

Theodore Louis Pulvermacher, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1915; served during the World War; aged 46; died, March 22, of pleurisy following an infection acquired while operating.

Henry Martyn Hall, Jr., Pittsburgh; Medical Department of the University of Illinois, Chicago, 1897; member of the Medical Society of the State of Pennsylvania; aged 44; died, January 11, of acute dilatation of the heart and chronic myocarditis.

Albert E. Griffin, Columbus, Ohio; Columbus Medical College, 1884; formerly president of the city council, and member of the board of education; for five years on the staff of the Franklin County Infirmary; aged 72; died, March 28, of heart disease.

John C. White, Seatonville, Ill.; M.R.C.S. and L.R.C.P., England, 1867, L.R.C.P., Edinburgh, and L.S.A., London, 1868; for many years postmaster of Seatonville; aged 79; died, March 22, at Decatur, of pneumonia following erysipelas.

Joseph Allen Mansfield Clark ⊕ Savona, Ohio; Michigan College of Medicine and Surgery, Detroit, 1898; past president of the Darke County Medical Society; aged 51; died, March 26, of tuberculosis of the spine.

John Henry Fochtman ⊕ Cozad, Neb.; College of Physicians and Surgeons, Baltimore, 1883; past president and secretary of the Dawson County Medical Society; aged 63; died, March 13, of heart disease.

Harry Fred Bushey, Camden, N. J.; Baltimore University School of Medicine, 1904; formerly county coroner and member of the board of health; aged 47; died, March 26, following a long illness.

Herschel Eugene Currey, Baker, Ore.; Kentucky School of Medicine, Louisville, 1893; California Eclectic Medical College, Los Angeles, 1897; aged 65; was accidentally shot and killed, March 21.

Herbert Spencer Gillette ⊕ Savona, N. Y.; Long Island College Hospital, Brooklyn, 1887; past president of the Steuben County Medical Society; aged 63; died, March 23, of heart disease.

Francis Irwin Burnell, South Norwalk, Conn.; Long Island College Hospital, Brooklyn, 1894; member of the Connecticut State Medical Society; formerly mayor of Norwalk; aged 64; died, March 18.

William Calvin Jarnagin, Atlanta, Ga.; University of Virginia Department of Medicine, Charlottesville, 1872; for five years president of the city board of health; aged 75; died, March 30.

Miloslav Francisci, Cleveland (licensed, Ohio, 1896); member of the Ohio State Medical Association; aged 71; died, January 19, of chronic endocarditis, diabetes mellitus and nephritis.

John H. Rohr, North Milwaukee, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1897; member of the State Medical Society of Wisconsin; aged 56; died, March 9.

Ralph Steans ⊕ Lewisburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1891; aged 62; died, March 20, at the Williamsport (Pa.) Hospital, of heart disease.

Frank Robert Humphreys, Bradford, Pa.; College of Physicians and Surgeons, Baltimore, 1895; served during the World War; aged 54; died, February 27, following a long illness.

John Joseph Burke ⊕ Schenectady, N. Y.; University of Vermont College of Medicine, Burlington, 1907; served during the World War; aged 49; died, March 11, of pernicious anemia.

Minor Morris ⊕ Alliance, Neb.; Medical College of Ohio, Cincinnati, 1890; served during the World War; aged 62; died, March 22, at St. Joseph's Hospital, of arteriosclerosis.

John McWilliam, London, Ont., Canada; Trinity Medical College, Toronto, 1880; L.R.C.S. and L.R.C.P., Edinburgh, Scotland, 1880; aged 72; died, February 10, of heart disease.

James Harwood Closson, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1886; formerly on the staff of St. Luke's Hospital; aged 63; died, March 26.

Ebenezer Lee Palmer, Noble, Ill.; Eclectic Medical Institute, Cincinnati, 1877; also a druggist; aged 71; died, March 23, at the Olney (Ill.) Sanitarium, of diabetes.

C. E. Vandiver, Ogallala, Neb.; Ensworth Medical College, St. Joseph, Mo., 1887; member of the Nebraska State Medical Association; aged 64; died, March 26, of heart disease.

James Starrett Dougal, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1893; aged 55; died, March 21, at the Jewish Hospital, of pneumonia.

Frank Herbert Tilton, Boston; University of Vermont College of Medicine, Burlington, 1879; member of the Massachusetts Medical Society; aged 69; died, March 24.

Cornelius M. England, Carthage, Mo.; Eclectic Medical Institute, Cincinnati, 1875; also a minister; Spanish-American War veteran; aged 84; died, March 23, of senility.

George Augustus Stickney ⊕ Beverly, Mass.; Medical School of Harvard University, Boston, 1882; on the staff of the Beverly Hospital; aged 68; died, March 22.

Jesse York Fitzgerald, Indian Trail, N. C.; Jefferson Medical College of Philadelphia, 1889; aged 58; died, March 12, of pneumonia.

Samuel H. Martin, Frankfort, Ky.; Medico-Chirurgical College of Philadelphia, 1905; aged 45; died, March 23, of heart disease.

Preston A. Peak, Greenville, Texas; Missouri Medical College, St. Louis, 1887; aged 63; died, March 10, following a long illness.

William John Boynton, Sutton West, Ont., Canada; Trinity Medical College, Toronto, 1900; aged 52; died, February 6, at Chatham.

William H. Kiester, Dayton, Ohio; Medical College of Ohio, Cincinnati, 1889; aged 69; died, March 16, of cerebral hemorrhage.

Charles F. Fickling ⊕ Butler, Ga.; Southern Medical College, Atlanta, 1893; aged 55; died, March 16, of cerebral hemorrhage.

John Henry Hannahan, Needham, Ind.; Kentucky School of Medicine, Louisville, 1893; aged 62; died, March 22, of pneumonia.

Charles Allen Martin, Manhattan, Kan.; Detroit Homeopathic College, 1902; aged 51; died, March 18, of bronchopneumonia.

Zacharach Bailey Ogden, Pittsburgh; University of Pittsburgh School of Medicine, Pittsburgh, 1896; aged 56; died, March 8.

James P. Davis, Gary, Texas (licensed, Texas, under the Act of 1907); aged 71; died, March 16, at Nacogdoches, of pneumonia.

George Snow Isham ⊕ Chicago; Chicago Medical College, 1884; aged 66; died, March 26, at Pinehurst, N. C., of pneumonia.

Burton Van Zandt ⊕ Schenectady, N. Y.; Albany Medical College, New York, 1896; aged 55; died, March 20, of myocarditis.

James W. Hardy, Winterville, Miss.; University of Tennessee College of Medicine, Memphis, 1886; aged 74; died, March 20.

Charles Rudolph Paradis, Regina, Sask., Canada; Laval University Faculty of Medicine, Quebec, Que., 1910; died, January 6.

Richard Heårn, Toronto, Ont., Canada; Victoria University Medical Department, Toronto, 1883; aged 63; died, February 27.

John William Moore, Brooklyn; Long Island College Hospital, Brooklyn, 1892; aged 61; died, March 15, at Jamaica, N. Y.

William Edwin Burton, Baltimore; Baltimore Medical College, 1897; aged 63; died, March 28, following a long illness.

Lemuel Edwin Guion, Waxhaw, N. C.; North Carolina Medical College, Charlotte, 1907; aged 43; died, February 27.

James G. Pope, Coleman, Texas; Vanderbilt University Medical Department, Nashville, 1898; aged 56; died in March.

John Henry Stork, Huntingburg, Ind.; Kentucky School of Medicine, Louisville, 1888; aged 67; died suddenly, March 12.

Lewis Hamilton Evans, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1868; died, February 1.

Edwin M. Hunt, Cincinnati; Pulte Medical College, Cincinnati, 1876; aged 72; died, March 12, of heart disease.

Paul Riche ⊕ New York; Long Island College Hospital, Brooklyn, 1907; aged 49; died, March 23, of myocarditis.

Albert C. Vose, Marion, Mass.; Pulte Medical College, Cincinnati, 1893; aged 72; died, March 24, of diabetes.

Nelson Frank Wetmore, Tacoma Park, Md.; Eclectic Medical Institute, Cincinnati, 1876; aged 73; died, March 15.

Louis T. Boatwright, Dowling Park, Fla.; Southern Medical College, Atlanta, 1880; aged 70; died, March 19.

John Tait, Washington, D. C.; Metropolitan Medical College, New York, 1854; aged 98; died, February 24.

George Earl McCorkle, Keysville, Va.; Rush Medical College, Chicago, 1888; aged 67; died, February 21.

Allan Noxon, Toronto, Ont., Canada; Hahnemann Medical College of Philadelphia, 1869; died, January 24.

E. D. Grigg, Verona, Mo. (licensed, Missouri, 1884); Confederate veteran; aged 88; died, March 14.

John H. Groff, Indianapolis; Medical College of Indiana, Indianapolis. 1892; aged 71; died, March 7.

Thomas J. Rich, Anna, Ill.; Miami Medical College, Cincinnati, 1872; aged 80; died, March 17.

Charles H. Mead, Battle Creek, Mich. (licensed, Michigan, 1900); aged 77; died, March 23.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

IDOZAN NOT ACCEPTABLE FOR NEW AND NONOFFICIAL REMEDIES

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

Idozan is an iron preparation manufactured in Denmark. According to the information furnished the Council by the distributor, Duomares Corporation, New York, the active medicinal ingredient of Idozan is "colloidal iron." According to the label, Idozan is composed of:

> "Iron 5 per cent; pure alcohol 6 per cent; sugar 10 per cent; flavoring 1 per cent; water 78 per cent."

Although this quantitative statement of composition would seem to require that the iron must be present in the metallic state, the advertising offers the information that in Idozan "the iron is in the form of the colloidal iron hydroxide as well as some crystalloidal iron salts."

Idozan, it is explained in the advertising, was produced to make possible the administration of large doses of iron recommended by some clinicians. It is stated: "In order to meet the requirements of modern therapeutics in this respect, experiments were carried out by eminent Danish investigators . . ." and that "by a special method of manufacture a solution was produced . . . ," namely, Idozan.

While these statements suggest that Idozan presents something new, the statement that it contains "colloidal iron hydroxide, as well as some crystalloidal iron salts" and the general behavior of the preparation would seem to indicate that it is essentially similar to the colloidal ferric hydroxide preparation which was in vogue as "dialyzed iron" in this country many years ago and which is described in the fifth (1910) edition of the German Pharmacopeia as Liquor Ferri oxychlorati dialysati.

The Council finds Idozan unacceptable for New and Nonofficial Remedies because the statement of its composition is indefinite and incorrect and because it is an unoriginal preparation marketed under a noninforming name.

BENZYL BENZOATE FOR THERAPEUTIC USE-VAN DYK AND CO., TWENTY PER CENT. AROMATIZED SUSPENSION MADE FROM BENZYL BENZOATE (VAN DYK AND CO.) (UNITED SYNTHETIC CHEMICAL CORP.), AND BENZYL ALCOHOL-VAN DYK & CO. OMITTED FROM N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

The Synthetic Drug Corporation (formerly the United Synthetic Chemical Corp.), New York, markets a brand of benzyl benzoate-"Benzyl Benzoate for Therapeutic Use (Van Dyk & Co.)" and a preparation of it—"Twenty Per Cent. Aromatized Suspension made from Benzyl Benzoate (Van Dyk & Co.)." The advertising for these preparations is based on the enthusiastic reports which were published when benzyl esters were first used experimentally in medicine and recommends the use of the firm's preparations in "Biliary Colic," "Ureteral or Renal Colic," "Hypertension," "(Asthma)," 'Mucous Colitis—Biliary Colic in these conditions it has been found to be equally as efficacious as opium," "Renal Colic; Enuresis when due to hyperirritable bladder and sphincter," "Asthma (True Bronchial Spasm) all data concerning the Benzyl therapy of asthma seems to show that Benzyl Benzoate is an invaluable drug in the treatment of asthma," "Arteriosclerosis."

In 1924 the Council reported (The Journal, Dec. 6, 1924, p. 1864) that extensive clinical use of benzyl esters does not seem to confirm the enthusiastic estimate of their early advocates and that the indications are that they will prove only of limited usefulness. An inquiry addressed to a number of clinicians disclosed an almost unanimous opinion against the value of these esters so far as most of the recommended uses were concerned. The benzyl esters apparently give relief in a certain proportion of cases of dysmenorrhea; a small percentage of angina and of intestinal colic appear to be benefited by their use. They have been found without effect in hypertension and they are probably without effect in asthma, or renal or biliary colic.

In consideration of the revised estimate of the therapeutic usefulness of benzyl esters, the Council urged the Synthetic Drug Corporation to undertake a revision of its advertising. This revision was not made. The Council therefore directed the omission of "Benzyl Benzoate for Therapeutic Use (Van Dyk & Co.)" and "Twenty Per Cent. Aromatized Suspension made from Benzyl Benzoate (Van Dyk & Co.) (United Synthetic Chemical Corp.)" from New and Nonofficial Remedies.

Benzyl Alcohol (Van Dyk & Co.) was accepted in 1919 as a brand of benzyl alcohol, N. N. R. Recently the distributors —Synthetic Drug Corporation—have adopted the name "Benzylol" for it and claim this name as a "word mark."

According to the label "Benzylol (Van Dyk & Co.)" was "accepted by the Council Pharm. and Chem. for N. N. R., 1919."

This is misleading. Neither Van Dyk & Co. nor the Synthetic Drug Corporation are the discoverers of benzyl alcohol and therefore the Council cannot recognize an exclusive name applied to the product by these firms.

The Council omitted Benzyl Alcohol (Van Dyk & Co.) from New and Nonofficial Remedies because it is no longer marketed under this name. It held "Benzylol" unacceptable because it is not in the interest of rational therapy that the well known substance benzyl alcohol be marketed under proprietary names.

BISMUTHAL OMITTED FROM N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

Bismuthal is a mixture containing an insoluble bismuth citrate and pepsin as its active ingredients, with hydrochloric acid and lactic acid to protect the pepsin, and flavoring ingredients. It was formerly marketed by the National Pharmacy Company, Oakland, Calif., and is now owned by Langley & Michaels Company, San Francisco.

Bismuthal was accepted in 1909. At that time an extended clinical practice of prescribing mixtures containing a bismuth preparation and pepsin appeared to the Council to justify its acceptance.

During recent years the prescribing of pepsin in combination with other therapeutic agents has been generally abandoned by physicians. This change is forcibly brought out in the report of W. A. Bastedo on "The Use and Utility of Digestive Enzymes in Therapeutics" (The Journal, Sept. 5, 1925, p. 743).

The Council directed the omission of Bismuthal from New and Nonofficial Remedies on the ground that the routine combination of a bismuth compound and pepsin in the form of a stock preparation is unscientific and not in the interest of rational therapy.

Tularemia with Conjunctivitis.—H. L. Freese, G. C. Lake and Edward Francis report four cases of tularemia with conjunctivitis, three with fatal termination, occurring in a family of eight persons in Lee County, Va., in 1925. Rabbits were often eaten by all members of the family except the mother, and that they were dressed by the mother or her husband. Apparently authentic information was obtained that a typical epidemic among rabbits had occurred in the locality in May, 1925. Although the bacillus of tularemia is readily killed in ten minutes at from 56 to 58 C., cooking experiments performed by the authors demonstrated the fact that an infected rabbit which has been insufficiently cooked would be dangerous as food.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ANAPHYLACTIC REACTIONS FOLLOWING TOXIN-ANTITOXIN INJECTIONS

To the Editor:—Have you any information on anaphylactic reactions following the administration of serums to children previously immunized against diphtheria with toxin-antitoxin? The planning of an immunization campaign in Ironwood has been interrupted by unfavorable reports coming from Minneapolis (Dr. Stewart's article, THE JOURNAL, January 9) and from Grand Rapids, Mich. Will you kindly give me your opinion and what information you have on the subject?

LOUIS DORPAT, M.D., Ironwood, Mich.

ANSWER.—S. B. Hooker (Human Hypersensitiveness Induced by Very Small Amounts of Horse Serum, *J. Immunol.* **9**:7 [Jan.] 1924) found that after toxin-antitoxin injections a noteworthy proportion of the persons became sensitive to horse serum when tested by specific intradermal reactions. William H. Park confirmed Hooker's results in general, but did not find any occasion from his experience in New York City to fear that the sensitizing effects of the toxin-antitoxin injections would lead to any serious results on subcutaneous or intramuscular injections of antidiphtheria serum later in persons free from evidences of status lymphaticus or horse asthma (*J. Immunol.* **9**:17 [Jan.] 1924). Dr. Stewart's recent report of anaphylactic reactions on injection of serum in seven children previously immunized against diphtheria by means of toxin-antitoxin indicates on the face of it that in certain cases sensitization may result from the toxin-antitoxin injections, but the possibility should be noted that for all we know severe reactions might have resulted in some at least of Stewart's cases, even if toxin-antitoxin had not been injected. In his report, Stewart does not say whether any of his seven patients were subject to horse asthma. In any case, there can be no question but that immunization against diphtheria without the introduction at the same time of foreign animal protein would be an advance of great advantage.

The letter of Dr. Dorpat, together with the reply, were submitted to Dr. W. H. Park of New York, who adds:

Dr. Stewart's recent report of anaphylactic reactions on injection of serum in seven children previously immunized against diphtheria by means of toxin-antitoxin stimulated me to make a comparative test of children who had and had not received toxin-antitoxin. The first test was in a group of seventy children, twenty-five of whom had had toxin-antitoxin and forty-five had received no toxin-antitoxin. They had been thoroughly exposed to scarlet fever and were given 10 cc. of antiscarlatinal serum. Within twenty-four hours some of the children began to develop higher temperatures and severe rashes, and within forty-eight hours twenty of the children were sick enough to remain in bed; some of the temperatures were as high as 104. The rashes were giant urticarial or scarlatinal in type, or the two types occurred in the same child. When the cases were compared as to the reaction in those who had and had not received toxin-antitoxin, there was no appreciable difference between them. (Dr. Park does not state whether serums were crude or concentrated—an important factor.—ED.)

As a further test I injected fifteen healthy children with 5,000 units of diphtheria antitoxin who had never received toxin-antitoxin injections, and fifteen healthy children with the same amount of diphtheria antitoxin who had had toxin-antitoxin injections. In none of these cases did any appreciable disturbance result, and there was practically no difference in the percentage of reactions in the two groups. It seems to me, therefore, that the reactions in the cases described by Dr. Stewart were not due to the fact the children had had toxin-antitoxin but rather to the fact that the antiscarlatinal serum is more apt to create disturbance than the diphtheria antitoxin. The reactions as described are not those of anaphylaxis but rather of serum sickness.

The question is now being studied in a number of laboratories as to the substitution of diphtheria toxoid for toxin-antitoxin. The toxoid is being used in Canada, in France and in Austria, while toxin-antitoxin or toxoid antitoxin is being used in the United States and in England. It is my belief that in a short time the diphtheria toxoid will be equally well standardized with toxin-antitoxin and that it will replace it, but there is no reason to hurry this change. It is better to use the toxin-antitoxin in the United States until the toxoid has been thoroughly proved and perfected, and then a final change should be made. We have in New York had no reason to believe that sensitization from the minute amount of serum in toxin-antitoxin creates any appreciable objection. At the present time the toxoid is more irritating in older children and adults because of the larger amount of protein it contains, while the toxin-antitoxin is slightly more irritating in young children because it is a slightly underneutralized mixture.

THE HUMAN RADIO AERIAL

To the Editor:—A friend of mine, a chemical engineer, discovered that the human body may act as a very good substitute for the usual radio aerial, but apparently not for *all* wave lengths. He has a five tube set. With either one of us touching the aerial connection, and the aerial disconnected from the set and ourselves, station KMOX (280 meters), for instance, can be brought in as plain as with the usual aerial. The detector dial setting, however, has to be quite different. The tighter the connection is gripped by the subject, the greater the volume. We have not been able to bring in KSD (545 meters) in this manner, although with the usual aerial it comes in very strong. The result is the same whether the subject stands directly on the floor or on a glass plate.

If the regular aerial is disconnected, and the set connected to about 60 feet of insulated copper wire wound on the lid of a cigar box, nothing can be brought in. If, now, one subject puts his hand on the insulated wire, KMOX can be brought in very well; the closer he presses his hand the larger the volume. If now the other subject puts his hand over another part of the insulated wire, the volume diminishes.

I am not a radio fan myself, but I am curious to know something about the physiology of these phenomena. Of what importance are they in the present state of our knowledge? Is there any literature on the subject? An answer, either through THE JOURNAL or direct, will be appreciated.

F. W. L. TYDEMAN, M.D., Wood River, Ill.

ANSWER.—All radio sets are tuned by adjusting inductance and capacity until the set as a whole is brought into resonance with the incoming carrier wave. The aerial is to be considered a part of the set, and changing its length will obviously change the inductance-capacity balance, and adjustment of the controls is necessary to bring again the set into resonance. When the human body was acting as an aerial, the equipment in the set was not adjusted (probably not adjustable) to the value necessary to bring the set into resonance at 545 meters.

Radio frequency discharges are not new. Electric motors, dynamos, storms and electrical disturbances of various kinds propagate them and they have been acting on the human body for years with an unknown but probably negligible effect. The physiologic effect of waves from radio broadcasting, to our knowledge, has never been discussed.

IRRITATION FOLLOWING SHAVING CREAMS

To the Editor:—I have had patients who complain of a condition resembling a mild eczema following prolonged use of soap-free shaving preparations (such as "Molle" and "Barbasol"). Have you information concerning the general composition of such preparations? Please use initials only.

H. W. S., M.D., Washington, D. C.

ANSWER.—These "soap free" shaving preparations are generally soaps, some of them prepared from potassium carbonate soaps containing spermaceti, others from potassium hydroxide or ammonium hydroxide with fats, egg white, alcohol and perfumes. Glycerin is also a frequent ingredient. Most of them are alkaline and may irritate as any soap does, by removing fat from the skin; others are superfatted. Irritation may be aggravated by the recommendation not to wash or rinse the face after shaving, but to permit the "cream" to dry.

PRESCRIPTION FOR HEXYLRESORCINOL

To the Editor:—Please advise me how I should write a prescription for hexylresorcinol, in both systems, for a girl of 13, with a *Bacillus coli* infection of the urinary tract, and also the adult dose of the drug.

A. L. H. MACNEILL, M.D., Cabri, Sask.

ANSWER.—Hexylresorcinol is best administered by mouth in elastic capsules, each capsule containing 0.15 Gm. in a 25 per cent solution in olive oil. The patient, being 13 years old, might be able to swallow such capsules. If not, it would be advisable to prescribe the 2½ per cent olive oil solution which is supplied by the manufacturer (New and Nonofficial Remedies Department, THE JOURNAL, Aug. 8, 1925, p. 437):

Caprokol (Hexylresorcinol-S. & D.) 2½ per cent solution in olive oil, 60 cc.

Label: Teaspoonful three times a day after meals.

GALVANIC AND FARADIC CURRENT FOR PARALYSIS

To the Editor:—I want to use a light galvanic and faradic current for such things as facial paralysis, and I am in doubt what to get, if any. I have been told that the wall plan (connected up with direct current) is the thing, by others that the small dry cell batteries are best. Can you let me know which is best? I favor the small battery on account of its portability, but I do not want it if it is not the thing.

Edward J. Bernstein, M.D., Detroit.

Answer.—For the purpose stated, the galvanic current from a dry cell battery is sufficient. The galvanic current should be used only when the muscles will not respond to the faradic current, and then only for a few contractions of each muscle. When the muscles respond to the faradic current, a good instrument to use is the Bristow coil, which gives a sinusoidal faradic current. The use of this instrument is fully described in Jones' "Orthopedic Surgery of Injuries."

STAINING FLAGELLA — BACTERIOPHAGE — HEMAGGLUTINATION

To the Editor:—1. Please publish the Plimmer, McCrorie and Shunk methods for staining flagella of motile bacteria. 2. What are bacteriophages? How are they cultivated and demonstrated? Can the specific bacteriophages be used beneficially for administration to patients having the corresponding infection? 3. Is it necessary to test blood for agglutination previous to transfusion in the case of a new-born child? Please omit name.

M. J., Wisconsin.

Answer.—1. In the Plimmer method (*J. Path. & Bacteriol.* **24**:286 [July] 1921), a film is prepared on a warm slide, allowed to dry in air, and not fixed. One part of stain is mixed with four parts of water in a tube, the tube is inverted three or four times, and the mixture is filtered on the slide. The stain is allowed to act for sixty seconds and is washed under the tap. The film is flooded with cold "carbolfuchsin" solution for five minutes, washed, dried and examined. The stain is made of

Tannic acid	10 Gm.
Aluminum chloride (hydrated)	18 Gm.
Zinc chloride	10 Gm.
Rosaniline hydrochloride	1.5 Gm.
Alcohol (60 per cent)	40 Cc.

The dry ingredients are placed in a mortar and triturated with 10 cc. of the alcohol. When a homogeneous paste is formed, the rest of the alcohol is slowly stirred in. A deep red, viscous solution is obtained.

In McCrorie's method (Partridge, Aids to Bacteriology, ed. 4, p. 53), a fixed film is stained for two minutes with a mixture of solutions A and B.

SOLUTION B

Tannic acid	1 Gm.
Hot water	20 Cc.

After solution, there is added 1 Gm. of alum dissolved in 20 cc. of cold water.

SOLUTION A

McCrorie's night blue	0.5 Gm.
Dehydrated alcohol	20 Cc.

A is added to B slowly, with gentle shaking.

The Shunk method (*J. Bacteriol.* **5**:181 [March] 1920) is a modification of Loeffler's method. A film is prepared on a cover slip and dried in air. It should not be fixed with heat. It is covered with 8 drops of solution A, and then 1 drop of solution B is added. After it has acted at room temperature for two minutes, it is washed with water and drained (not blotted). It is stained for two or three minutes, washed, allowed to dry, and examined.

SOLUTION A

Ferric chloride solution, 1:20	1 part
Tannic acid, saturated solution	3 parts

SOLUTION B

Aniline	1 part
Alcohol, U. S. P.	4 parts

STAIN

Methylene blue, saturated alcoholic solution	30 parts
Potassium hydroxide solution, 1:10,000	100 parts
Solution B	13 parts

2. Some years ago, Twort observed transparent areas in growths of certain staphylococcus cultures. The organisms had apparently been dissolved. The lytic substance could be transferred to other cultures. Later, d'Herelle noticed the same phenomenon with dysentery cultures, found the lytic principle in filtrates from cultures, and obtained it in stools from dysentery patients. This lytic substance is known as bacteriophage. The nature of the bacteriophage is still a matter of dispute, particularly as to whether it is a living organism or is nonliving material formed during bacterial metabolism, possibly related to enzymes. The best method of demonstration is by means of agar plate cultures. The specificity of the bacteriophage is doubtful (Bacteriophage News, editorial, The Journal, Dec. 26, 1925, p. 2037). Attempts have been made to use bacteriophage as a therapeutic agent, but uniform success has not been attained.

3. When blood transfusion is made in new-born babies by means of intramuscular injections, it is not necessary to type the blood. For intravenous injection, blood should be typed.

COAL TAR ODOR—TREATMENT OF GASOLINE POISONING

To the Editor:—1. One of our butchers had a refrigerator built in his shop. It was lined with cork and coal tar, and lastly plastered over the cork and tar. Meat stored in it takes on the smell of coal tar. Is there some fumigation that will neutralize the effect of the coal tar? 2. What is the best treatment for a patient who has swallowed gasoline?

Gaylord Worstell, M.D., Big Sandy, Mont.

Answer.—1. The only solution is to correct the condition at the source. Free circulating cold air would be the only safe agency to apply to the affected meat, and it is a question, of course, how effective this would be.

2. In the treatment of gasoline poisoning, evacuation of the stomach by emetics, and preferably by lavage, is the most important item to secure. It seems that, owing to the insolubility in and immiscibility of the agent with water, liberal quantities of oil might be used with advantage in the lavage, the oil to be subsequently removed as completely as possible by washing with water. There is no known antidote. Artificial respiration should be instituted early if there are indications of failure of respiration, and maintained resolutely for as long a time as there may seem the least possibility of resuscitation, as we deal here with an agent that not only depresses the respiratory center, but is also especially and rather rapidly eliminated by way of the respiratory tract. Possibly respiratory stimulants such as strychine or atropine may be of use. Emollients and protectives are to be employed in the treatment of resulting gastro-intestinal irritation.

FABRE'S TEST FOR BARBITAL

To the Editor:—In The Journal, April 11, 1925, reference was made to Fabre's test for barbital. As I have been unable to locate the technic for this, will you please provide me with this information?

R. C. Satterlee, San Diego, Calif.

Answer.—The chemical reaction is based on the formation of certain crystalline dixanthyl compounds of hypnotics derived from barbituric acid, developed in the presence of acetic acid which among other characteristics are identifiable by their melting points. The procedure is: To an acetic acid solution of barbital (1 Gm. to 10 cc. of acetic acid), 2 Gm. of xanthydrol is added. The mixture is brought to the boiling point; on cooling, a crystalline precipitate is produced, which slowly becomes more abundant. After a few hours, the latter is allowed to dry (centrifugalized) and the excess of barbital and of xanthydrol are removed by successive washing with hot alcohol. It is recrystallized from benzene in the form of small colorless prismatic crystals, melting at from 245 to 246 C. The crystals are soluble in benzene and slightly soluble in acetic acid and warm alcohol. In his article (Sur une réaction du véronal et des hynotiques dérivés de l'acide barbiturique, applications, *J. de Pharm. et de chim.* **2**:241, 1922) René Fabre gives the technic that should be followed for the toxicologic determination of barbital and its derivatives using this reaction.

AMERICAN CARBONIC ACID NAUHEIM BATHS

To the Editor:—In Queries and Minor Notes (The Journal, March 6, p. 709) I saw the information you give in regard to carbonic acid Nauheim baths. You do not mention the springs of which I spoke in my book on Sexual Impotence (ed. 6, Philadelphia, W. B. Saunders Company, 1920). These springs, unfortunately, were called Vichy, which only shows the ignorance of the owners. It is, however, a fact that these springs outnauheim in every respect Nauheim itself, and anything that ever was attempted in the shape of carbonic acid gas baths.

The water of these springs, located near Ukiah, in California, has the proper temperature and flows day and night. I personally consider these baths excellent, but, and again unfortunately, the accommodations and the table are rather modest, and the modern luxury-loving public ignores the place.

Victor G. Vecki, M.D., San Francisco.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

American Board of Otolaryngology, Texas: Dallas, April 19, California: San Francisco, April 27. Sec., Dr. H. W. Loeb, 1402 South Grand Boulevard, St. Louis, Mo.

Arkansas: Little Rock, May 11-12. Sec., Dr. J. W. Walker, Fayetteville. Homeo. Board, Little Rock, May 11. Sec., Dr. A. A. Pringle, Eureka Springs. Eclectic Board, Little Rock, May 11. Sec., Dr. Claude E. Laws, Fort Smith.

Georgia: Atlanta, June 9-11; Augusta, June 1-3. Sec., Dr. C. T. Nolan, Marietta, Ga.

Michigan: Ann Arbor, June 8-10. Detroit, June 14-16. Sec., Dr. Guy L. Connor, 707 Stroh Bldg., Detroit.

National Board of Medical Examiners: Part I, June 21-23; Part II, June 22-23. All applications should be made on or before May 15. Sec., Dr. J. S. Rodman, 1600 Walnut Street, Philadelphia.

Nebraska: Omaha, June 8-10. Director, Bur. of Exam. Bds., Mrs. Clark Perkins, Lincoln.

Nevada: Carson City, May 3. Sec., Dr. Simon L. Lee, Carson City.

Colorado January Examination

Dr. David A. Strickler, secretary of the Colorado Board of Medical Examiners, reports the written examination held at Denver, Jan. 5, 1926. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Of the 10 candidates who took the physicians' and surgeons' examination, 5, including 1 undergraduate, passed and 5, including 2 osteopaths, failed. Fourteen candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
College of Physicians and Surgeons, Boston	(1925)	84.1
Kansas City University of Physicians and Surgeons	(1924)	76.3
National University of Ireland, Dublin	(1924)	83.1
University of Amsterdam, Netherlands	(1919)*	89.3
Undergraduate		80.5

College FAILED	Year Grad.	Per Cent
Kansas City College of Medicine and Surgery	(1924)	64
St. Louis College of Phys. and Surgs.	(1923) 70.8, (1924)	73.8
Osteopaths		64.8, 73

Kansas February Examination

Dr. A. S. Ross, secretary of the Kansas State Board of Medical Registration and Examination reports the written examination held at Topeka, Feb. 9-10, 1926. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Eight candidates were examined, all of whom passed. Ten candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine	(1925)	92.1
Chicago Homeopathic Medical College	(1902)	80
Rush Medical College	(1900)	93.8
St. Louis University School of Medicine	(1925) 86.6, (1926)	88.8
University of Pennsylvania School of Medicine	(1925)	90.8, 90.9
Meharry Medical College	(1925)	89.3

Book Notices

Insulin. Its Use in the Treatment of Diabetes. Part I—Physiology. By J. J. R. Macleod, Departments of Medicine and Physiotherapy, University of Toronto. Part II—Clinical Section. By W. R. Campbell, Departments of Medicine and Physiotherapy University of Toronto. Medicine Monographs. Volume VI. Cloth. Price, $4. Pp. 242, with 6 illustrations. *Baltimore: Williams & Wilkins Company, 1925.*

In this volume the authors bring together much of the work that has already appeared in various publications. The first part deals with points of historical interest, a description of the methods of preparation of insulin, the sources of supply and the theories of its action. Beginning with the effects of pancreatectomy as first described by Minkowski, the authors trace the development of the study of diabetes through the work of Szobalew, Schults, Zuelzer, Knowlton, Starling, Grey, Scott, Murlin and Kleiner to that culminating in the discovery of insulin by Banting and Best. Several methods of preparation of insulin are described. The theory of the action of insulin most acceptable to the authors is that insulin has some effect on sugar metabolism which helps glucose to pass through a glycogen state, in order to proceed to final oxidation. Although absolute proof of this theory is not at hand, experimental evidence favoring this view has been adduced. The action of insulin in restoring to normal the migration of fat between the liver and the tissues, its effect on oxidation and on raising the respiratory quotient, its varying action on protein-derived and actual carbohydrates, its effect on the passage of sugar through the tissues, the association of carbohydrates and phosphates (the hexo phosphates) and the determination of the value of the unit are described in detail. The second part is devoted to a clinical consideration of insulin in metabolism, the diagnosis and treatment of diabetes and a listing of many diets, tables and recipes for the physician's use. That "insulin is a crutch which slips at times" is a statement worth remembering. Dr. Campbell recommends the slow addition of insulin and agrees with many workers that the maintenance of a low blood sugar is advisable. The thoroughness and simplicity, its conservatism, and the excellent manner of presentation, together with its intrinsic value, will recommend this book to all physicians and students of diabetes.

Die Chirurgie. Eine zusammenfassende Darstellung der allgemeinen und der speziellen Chirurgie. Herausgegeben von Prof. Dr. M. Kirschner und Prof. Dr. O. Nordmann. Lieferung 5, Band VI. Die Chirurgie der Niere, des Nierenbeckens und des Harnleiters. Von Prof. Dr. P. Frangenheim und Priv.-Doz. Dr. E. Wehner. Die Chirurgie der Harnröhre. Von Priv.-Doz. Dr. E. Wehner. Die Chirurgie des Penis und Scrotums. Von Priv.-Doz. Dr. E. Wehner. Die Chirurgie des Hodens, Nebenhodens, Samenstranges und der Scheidenhäute. Von Priv.-Doz. Dr. E. Wehner. Paper. Price, 27 marks. Pp. 229-750, with 108 illustrations. Berlin: Urban & Schwarzenberg, 1925.

The fifth section of this work is devoted to the surgery of the kidney, ureters and male genitalia. The method of dealing with the various topics is similar to that in the sections which have thus far appeared. The subject matter, however, is treated much more comprehensively and at greater length. The first part of the book, the part dealing with the kidney and ureters, is written by Frangenheim and Wehner, and the rest of the book by Wehner.

The Science of Biology. An Introductory Study. By George G. Scott, Ph.D., Associate Professor of Biology in the College of the City of New York. Cloth. Price, $3.50 net. Pp. 617. New York: Thomas Y. Crowell Company, 1925.

The author apparently conceived a plan that he was unable to justify in his unhappily named textbook. In general, this plan is that laid down by the taxonomist. To treat plants and animals virtually order by order, along with a consideration of all branches of biology, in a single book, presents a stupendous task which should require much thought as to organization and balance, in addition to thorough command of scientific fact. But it is difficult to say whether the chaotic arrangement of material or the complete innocence of scientific knowledge is the more glaring. The text is couched in pitiful English, which of itself would convey a confused meaning.

A jerky style, in which sentence follows sentence with no evident interrelationship, contributes to the general confusion. On page 447, one marvels at the extremes to which precocity goes when "Cases have occurred in which there was an unusually early development in children of secondary sex organs." It is implied on page 310 that the egg of the duckbill can swim: "Eggs, about ¾ inch long, with yolk and a shell, are laid at the ends of burrows in river banks. The animal is also aquatic in its habits." Again, on page 255 a strange picture comes to mind where the dogfish "skull consists of a cartilaginous box-like cranium enclosing the brain and the visceral skeleton." In a paragraph on spawning (page 267) the closing sentences are: "Some eggs hatch in less than a day's time. A month is needed in the case of salmon. Some deep sea fish have *luminescent* organs." Practically every page offers similar examples. Even more surprising are the gross errors of fact. On page 319 we learn that "the narwhal has a long, twisted bony beak in front." Conscientious taxonomists will note with alarm that the badger, marten and weasel (page 329) are no longer mustelids, but bears (Ursidae). The homologies which the author apparently implies (pages 357-358) between the anterior and the posterior limbs are thoroughly misleading. Assuming that Professor Scott wished to avoid presenting involved or complicated ideas to immature students, it is decidedly unfair, even for the sake of simplicity, to create erroneous impressions. Moreover, he cites difficult chemical and biometric formulas which assume well advanced training on the part of the reader. With the word Diptera before him, Professor Scott describes them (page 235) as "the flies which have two pairs of wings on the mesothorax." Practically every school boy knows that no spider or daddy long legs has pincers, but in the description of the class Arachnida (page 245) "the first pair of appendages are nippers." In view of the frequent descriptions of the evolution of the horse, it would seem scarcely possible to go far wrong. In two pages (478-480) there are no less than nine errors and nine verbal *infelicities.* One example should be more than enough. "The upper surface of the teeth is ground flat and continued to grow as it wore away." Instances could be multiplied, but a fitting climax can be quoted from the section on Carnivora (page 327): "Their movements [are] full of grace and beauty oftentimes marred by stealth and cunning." There are a number of original drawings which, on the whole, are on a par with the text in value and accuracy. On page 225, in the diagram of the intestinal tract of the cockroach, various parts are mislabeled and the intestine is omitted entirely. Other figures (pages 180, 250, 275 and 296) are fortunately labeled to aid in recognition. The large number of illustrations reproduced from other sources are distinctly the best part of the book. Many of them are worthy of a better fate.

Abhandlungen aus der Neurologie, Psychiatrie, Psychologie und ihren Grenzgebieten. Herausgegeben von K. Bonhoeffer. Heft 32. Familienpsychosen im schizophrenen Erbkreis (Psychosen bei den Eltern von Dementia Praecox-Kranken). Von Dr. Hermann Hoffmann, Privatdozent für Neurologie und Psychiatrie an der Universität Tübingen. Paper. Price, 7.20 marks. Pp. 120, with 8 illustrations. Berlin: S. Karger, 1926.

The author has studied the families of patients with schizophrenia and determined the psychosis present in each member. He roughly classifies each of the individuals of his series, according to the modern trend, into schizoid, cyclothymic and mixed personalities. He gives the following interesting figures: in schizophrenic patients, both parents were schizoid in 52 per cent, one parent in 46 per cent, and neither parent in only 2 per cent. Between 40 and 50 per cent of the collaterals were schizoid, 25 per cent cycloid, and only 11 per cent of the mixed type. The author finds that the majority of schizophrenic patients come from families which have contained one or more members suffering from the same psychosis. The same observation holds true for manic-depressive insanity. In both these groups, the patient before the development of his psychosis is usually schizoid in the schizophrenic and cyclothymic in the manic-depressive. When a patient with schizophrenia has had a cyclothymic personality, his psychosis is not typical, and when it has been schizoid his psychosis is pure and has a typical symptomatology. The author believes that for each great group of psychosis there is a specific anlage which is inherited in the form of a general disposition for the development of a type of psychosis. His statistical work is convincing.

Acute Infectious Diseases. A Handbook for Practitioners and Students. By J. D. Rolleston, M.A., M.D., Senior Assistant Medical Officer, Grove Fever Hospital, London. Cloth. Price, $5. Pp. 376. New York: Physicians & Surgeons Book Company, 1925.

Dr. Rolleston has written clear and brief accounts of the chief acute infectious diseases, those ordinarily treated in isolation hospitals. Typhoid and typhus fevers are included, but poliomyelitis, encephalitis and others are not. The clinical aspects, symptoms and treatment are given fully, the etiology and morbid changes more briefly. Some of the recent advances in the field are discussed, such as the prevention of measles with the blood and serum of convalescents, although there is no mention of the treatment of scarlet fever with antitoxin. The historical notes at the beginning of each chapter are interesting, and the bibliographic notes at the end are helpful in further reading on the various subjects.

Pathologisch-anatomische Studien über die Osteodystrophia fibrosa (Sog. Ostitis fibrosa v. Recklinghausen). Akademische Abhandlung zur Erlangung der medizinischen Doktorwürde mit Genehmigung der weiterfahrenen medizinischen Fakultät zu Uppsala Vorgelegt. Von Ture Stenholm. Fil. Mag., Norrl. Paper. Pp. 211, with illustrations. Uppsala: Almqvist & Wiksells, 1924.

This discusses the subject of osteitis fibrosa of von Recklinghausen from the standpoint of pathologic anatomy. Twelve cases are reported. Various types of osteitis fibrosa are discussed, chiefly under the two headings of (1) metaplastic malacia, or *osteitis fibrosa of von Recklinghausen,* and (2) hypertrophic metaplastic malacia, or osteitis deformans of Paget. The monograph contains a complete bibliography, and several excellent illustrations, some of which are in color.

Methods in Surgery. Used in the Surgical Divisions of Barnes Hospital, St. Louis Children's Hospital, and Washington University Dispensary. Including outlines for case history-taking, preoperative and postoperative care of patients, routines, diets, etc. By Glover H. Copher, M.D., Instructor in Surgery, Washington University School of Medicine. Cloth. Price, $3. Pp. 232. St. Louis: C. V. Mosby Company, 1925.

This is a working manual of hospital routine written primarily for the guidance of house officers and students of Washington University School of Medicine working in the surgical divisions of Barnes Hospital, the St. Louis Children's Hospital, and the Washington University Dispensary. The chapters embrace history taking, roentgen-ray department rules, ward and operating room routine, postoperative treatment, and care of special types of cases, as in plastic, neurosurgical, gynecologic and genito-urinary operations. The book is brief, yet covers the material in close detail. A complete set of chart forms and special diets is presented. Since it represents the work of an excellent hospital organization, it merits the attention of the resident staff of other hospitals and also of the young surgeon in practice.

La tétanie infantile. Recherches cliniques et expérimentales. Par. R.-A. Turpin. Préface du Docteur E. Lesne. Paper. Price, 16 francs. Pp. 223, with illustrations. Paris: Masson et Cie, 1925.

This is an excellent combination of experimental and clinical medicine. Furthermore, it has the advantage of expressing the personal work of the author. A sufficient historical and bibliographic division, and a comprehensive discussion of modern conceptions of the acid-base balance of the body make it complete. The relationship of alkalosis and blood calcium deficiency to spasmophilia and to tetany is well brought out, particularly in the detailed case reports. The outline of the analytic methods is adequate.

Handbook of Pathology. By C. Y. Wang, M.D., B.Sc., F.R.C.P., Professor of Pathology in University of Hongkong. Cloth. Price, $7. Pp. 513, with 282 illustrations. New York: William Wood & Co., 1925.

This is a short descriptive pathology, a classification of the chief morbid changes, with their etiology, and gross and microscopic appearance as they occur in the different organs. There is no theoretical discussion and no discussion of controversial subjects, such as the pathogenesis of edema or the origin of tumors. The material is arranged according to the etiology or the character of the changes, without a special part dealing with the pathology of the different organ systems. The book would be useful chiefly for students as a preliminary survey of the subject and would have to be supplemented by a more extensive work. Its small size and brevity make it convenient for rapid reference or review.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Anatomie cérébrale les noyaux gris centraux et la région mésencéphalo-sous-optique. Suivi d'un appendice sur l'anatomie pathologique de la maladie de Parkinson. Par Ch. Foix, professeur agrégé a la Faculté de médecine de Paris, et J. Nicolesco, assistant d'histologie a la Faculté de médecine de Bucarest. Cloth. Price, 100 francs. Pp. 581, with 62 illustrations. Paris: Masson & Cie, 1925.

Neurologic anatomy, with especial reference to Parkinson's disease.

Étude analytique et synthétique de la sympathectomie périartérielle appliquée au traitement des ulcères chroniques des membres inférieurs. Physiopathologie et résultats immédiats et éloignés de la denudation arterielle. Par le Docteur Guillermo García-Diaz, de la Faculté de médecine de Paris et de Buenos-Aires. Paper. Pp. 281, with illustrations. Paris, Le François, 1925.

Periarterial sympathectomy for ulcers of the leg.

Clinique médicale de l'hôpital Beaujon. Par Ch. Achard, Professeur de clinique medicale a la Faculté de médecine de Paris. Deuxième série. Paper. Price, 24 francs. Pp. 336, with 66 illustrations. Paris: Masson & Cie, 1925.

Considerations of gout, diabetes, syringomyelia and cirrhosis of the liver, based on study of specific cases.

Health Control in Mercantile Life. A Problem of Conserving Human Energy. By Arthur Brewster Emmons, 2d, A.B., M.D., Director, Harvard Mercantile Health Work, Boston. Cloth. Price, $3. Pp. 234, with illustrations. New York: Harper & Brothers, 1926.

Easily readable study of health conditions in stores, well illustrated and full of practical advice.

Ophthalmic Neuro-Myology. A Study of the Normal and Abnormal Actions of the Ocular Muscles from the Brain Side of the Question. By G. C. Savage, M.D., LL.D. Second edition. Cloth. Price, $3. Pp. 227, with illustrations. Nashville, 1926.

New edition of standard work, with some revisions because of new discoveries as to ophthalmic axes of rotation.

A Manual of the Parasitic Protozoa of Man. By Charles F. Craig, M.D., M.A., Lieutenant-Colonel, Medical Corps, U. S. Army, D.S.M. Cloth. Price, $7. Pp. 569, with 95 illustrations. Philadelphia; J. B. Lippincott Company, 1926.

Complete and authoritative presentation for use of student and practitioner.

Handbuch der Physiologie der niederen Sinne. Von Emil von Skramlik, a. o. Professor der Physiologie an der Universitat, Freiburg, i. B. I Band. Die Physiologie des Geruchs und Geschmackssinnes. Paper. Price, 31.50 marks. Pp. 532, with 70 illustrations. Leipsic: Georg Thieme, 1926.

Highly technical details on physiology of smell and taste.

Episodische Dämmerzustände. Ein Beitrag zur Kenntnis der konstitutionellen Geistesstörungen. Von Professor Dr. K. Kleist, Direktor der psychiatrischen und Nervenklinik Frankfurt a. M. Paper. Price, 3.60 marks. Pp. 80. Leipsic: Georg Thieme, 1926.

Case reports and psychiatric studies of various psychopathic types.

Methods of Investigating Ventilation and Its Effects. By H. M. Vernon and Others. Medical Research Council. Special Report Series, No. 100. London: His Majesty's Stationery Office, 1926.

Shows that temperature and clothing are more important in regulating body temperature than is air velocity.

Food Prescriptions for Overweight. By Harrington Bennett Monroe, M.D. Cloth. Price, $1.50. Pp. 50. Los Angeles: McCulloch Press, 1925.

Sensible advice, sensibly presented.

Old Masterpieces in Surgery. Being a Collection of Thoughts and Observations Engendered by a Perusal of Some of the Works of Our Forebears in Surgery Which Appeared in Serial Form in Surgery, Gynecology and Obstetrics During 1924 and 1925. By Alfred Brown, M.D. Privately published. Omaha, 1926.

Well illustrated collection of essays of historical interest.

Nephritis. By Herman Elwyn, M.D., Assistant Visiting Physician, Gouverneur Hospital, New York, N. Y. Cloth. Price, $5. Pp. 347, with 2 illustrations. New York: Macmillan Company, 1926.

Complete presentation of modern knowledge, based on literature and experience.

Diagnosi e Terapia Clinica degli Avvelenamenti. Guida per medici e studenti. Por Dott. Guisto Coronedi, Professore di Farmacologia nella R. Universita. Cloth. Pp. 310, with illustrations. Florence: G. Barbèra, 1926.

Students' manual of little general value.

Die Persönlichkeitsanalyse. Eine vorbereitende Methode für jede Psychotherapie der Neurosen. Von Dr. Ernst Jolowicz, Nervenarzt in Leipzig. Paper. Price, 2.10 marks. Pp. 83. Leipsic: Georg Thieme, 1926.

System of study for psychotherapists.

Hygiene of Sex. By Max von Gruber. Cloth. Price, $1.50. Pp. 169, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

Sound presentation, plain spoken, but in language a little technical for those under high school intelligence.

Le rêve et la psychanalyse. Par le Dr. R. Laforgue. Avec la collaboration des docteurs Allendy, Ed. Pichon, R. de Saussure. Introduction de M. le Dr. Hesnard, Professeur de l'Ecole médecine navale de Bordeaux. Paper. Price, 12 francs. Pp. 248. Paris: A. Maloine, 1926.

Poorly printed on poor paper, and not especially scientific.

Lexikon der Ernährungskunde. Herausgegeben von Dr. E. Mayerhofer, Professor an der Universität, Zagreb, und Dr. C. Pirquet, Professor an der Universität, Wien. Lieferungs 3 und 4. Paper. Pp. 337-892. Vienna: Julius Springer, 1925.

Letters G through M of a German dictionary of nutrition.

Les tumeurs du cerveau. Par le Professeur Viggo Christiansen, Médecin en chef de l'Hôpital royal du Danemark. Avec une préface du Pr. Pierre Marie. Second edition. Paper. Price, 45 francs. Pp. 398, with 107 illustrations. Paris: Masson & Cie, 1925.

Complete study of tumors of the brain and spinal cord.

Fresh Air and Ventilation. By C.-E. A. Winslow, Professor of Public Health, Yale School of Medicine. Cloth. Price, $2. Pp. 182. New York: E. P. Dutton & Co., 1926.

Complete and quite practical consideration of a timely subject, interesting to both physician and public.

Der Hohlfuss. Seine Entstehung und Behandlung. Von Dr. M. Hackenbroch, Privatdozent, Oberarzt der orthopädischen Klinik, Köln. Paper. Price, 6.60 marks. Pp. 83, with 40 illustrations. Berlin: Julius Springer, 1926.

Monograph on common subject suitable to specialists.

Las Glandulas Morfogenas y la Vejez. Discurso leido en la real Academia de Medicina y Cirugia de Barcelona el dia 15 de Noviembre de 1925, en el acto de la recepsión del académico electo. Por Dr. Jesus M. Bellido Golferichs. Discurso de contestación del académico numerario. Por Augusto Pi Suñer. Paper. Pp. 37. Barcelona, 1925.

The Pharmacopoeia of the United States of America. Tenth Decennial Revision (U. S. P. X.). By authority of the United States Pharmacopoeial Convention. Official from January 1, 1926. Cloth. Price, $4. Pp. 626. Philadelphia: J. B. Lippincott Company, 1926.

Bericht der Sondertagung des Vereins der Aerzte für Nervenmassage. Berlin, 14, und 15. April 1925, sowie der ordentlichen Sitzungen des Vereins, vom 8, September und 24, Oktober, 1925. Paper. Price, 3.60 marks. Pp. 104. Leipsic: Georg Thieme, 1926.

Le terrain hérédo-syphilitique. Aperçu de pathologie générale et de clinique infantiles. Par V. Hutinel, Professeur honoraire de clinique médicale infantile. Paper. Price, 30 francs. Pp. 455. Paris: Masson & Cie, 1926.

Registry and Return of Births, Marriages and Deaths, and of Divorce, in the State of Rhode Island for the Year Ending December 31, 1923. Seventy-first report. Providence, 1925.

"Kinésie paradoxale" des parkinsoniens. Contribution à l'étude du mécanisme de la motilité volontaire. Par Dr. J. Jarkowski. Paper. Price, 12 francs. Pp. 78. Paris: Masson & Cie, 1925.

Les angines de poitrine. Par Louis Gallavardin, Médecin des hôpitaux de Lyon. Price, 25 francs. Cloth. Pp. 181. Paris: Masson & Cie, 1925.

Proceedings of the Fortieth Annual Meeting of the Conference of State and Provincial Health Authorities of North America. 1925.

Les cinq sens. Les curiosités de la médecine. Par le Docteur Cabanès. Paper. Pp. 308. Paris: E. Le François, 1926.

French Benevolent Society of New York. Annual Report for the year ending September 30th, 1925.

Miscellany

CLINICAL THERMOMETERS

BRADFORD NOYES, JR., PH.D.
Rochester, N. Y.

Of all the instruments used by the physician, none is more essential than the clinical thermometer.

In view of legislation already passed in several states, and of some agitation for a national law controlling the manufacture and sale of this type of thermometer, it was thought desirable that an exhaustive study be made of clinical thermometers. This investigation is now complete, and the results will be published at an early date.[1] In this instance the work of Waidner and Fischer[2] was of assistance.

The physician must have a thermometer correct within certain limits of accuracy. What these limits are is best determined by the physician himself, and the clinical thermometer manufacturer will try to meet the demand. The physician wants a good thermometer, but he does not want to pay for value that is not received. To require a thermometer manufacturer to carry a stock of half a hundred kinds of thermometers, each marked with the seal of a particular state, is an obvious burden, which must be passed on to the purchaser.

No matter how strict the inspection of the various laboratories, much must be left to the integrity of the manufacturer. It is the unseen thing, the care in manufacture, that makes true value. In the following paragraphs, an attempt is made to explain briefly some of the factors to be considered.

The first material that goes to make up a clinical thermometer is the glass. If it is made of certain grades of glass, and not properly aged before pointing, errors as high as 0.6 degree F. are liable to develop after several months' use. The use of a good quality of glass will reduce this source of error to about 0.1 degree F., and if the thermometer is properly aged it becomes entirely negligible.

The quality of the mercury with which the thermometer is filled is of prime importance. An average human hair is twenty times as large as some of the capillary used, and any impurity in the mercury detracts from the reliability of the instrument.

The device that causes the clinical thermometer to register the highest temperature to which it has been exposed is called the contraction. It consists essentially of a constriction in the tube, which allows the mercury to pass upward when forced by the mercury below, but prevents it flowing back without the application of some force. The formation of the contraction requires great skill on the part of the workman. Unfortunately, he is unable to make each just alike.

Some contractions allow the mercury to flow upward in a continuous stream, while in others it goes up in a series of jumps. The first type is liable to be a retreater; that is, it allows the mercury to run back. In fact, there is reason to believe that every thermometer with this kind of contraction will, if cooled slowly enough, retreat. It should be pointed out, however, that in ordinary practice the thermometer is removed from the patient's mouth, and allowed to cool quickly to room temperature. One laboratory, in testing for "retreaters," cools the thermometer very slowly. This is not a condition that exists in actual use, and, in my opinion, seems unnecessarily severe.

The second type of contraction, that which always allows the mercury to pass through in jumps, has one great advantage—it is never a retreater. But there are also disadvantages. If the jumps are large, the thermometer cannot be depended on for accurate readings. If the amount of mercury per jump corresponded to 0.4 degree F., in the bore, the thermometer might well be in error by that amount, and may fail to repeat by as much as 0.8 degree F. However, if the jumps are small, such thermometers are to be desired. The value 0.4 degree F. is exceptional, being the largest jump I have seen. More often the jumps amount to about 0.1 degree F. As a usual thing, thermometers which shake down easily either have big jumps or are liable to be retreaters. This is not always true, for thermometers have been found which the Bureau of Standards would reject as hard shakers, and which one state laboratory would reject as retreaters.

The space above the mercury in a clinical thermometer is carefully evacuated, but of course it is absolutely impossible to remove all the gas. This gas above the column does no harm, unless its pressure is sufficient to cause an otherwise perfect tube to retreat. Most regulations wisely permit a certain amount of gas above the column. Gas which remains in the contraction is liable to separate the mercury column, and will cause an error equal to the length of air space. In some cases, this air space is so small as to be visible only under a microscope, and does not cause complete separation of the mercury column. The inaccuracies caused by such air space are negligible, and may be disregarded. As most regulations on this subject are poorly worded, some testing laboratories are entirely too severe, while others pay entirely too little attention to this source of error. It is suggested that any tube be rejected in which the air space is sufficient to cause complete separation of the mercury. This is severe enough for all practical purposes, but not an impossible requirement for the manufacturers to meet.

Each clinical thermometer has to be individually "pointed." That is, a small file mark is placed on the tube opposite the top of the mercury when the bulb is placed in a bath of known temperature. Two such marks are placed on each tube, one corresponding to a temperature of 96 F., the other corresponding to 106 F. Different manufacturers use different temperatures for the points, but the method is the same in each case. To maintain proper apparatus requires considerable outlay of capital. Special baths have to be provided, the temperature of which may be accurately controlled, and the water must be constantly agitated by mechanical means. Standard thermometers must be procured and subjected to periodic calibration.

After being pointed, the tubes are waxed and sent to the engraving department. Here an engraving machine is so set that the 96 F. and 106 F. points fall on the file marks previously described. The machine graduates the intervening space into the proper number of equal spaces, and the thermometer is then ready to be etched.

The certification requires more water baths, more standard thermometers and more skilled help. It is here that the thermometer is given its final inspection and unreliable tubes rejected.

In the foregoing, I have not attempted to give the details of manufacture. Points have been discussed which are thought to interest the medical man. An attempt has been made to show that much depends on proper manufacture, and this requires much more capital than most readers imagine. The safest thing for the physician to do is to buy good thermometers, made by manufacturers of recognized standing.

Medicolegal

Practice Act Should Receive Reasonable Construction

Levin v. Board of Medical Examiners of California et al. (Calif.), 239 Pac. R. 410)

The District Court of Appeal of California, first district, division 1, says that the petitioner asked for mandate to compel the board of medical examiners to issue to him a license entitling him to practice medicine and surgery in the state of California. He alleged that he had taken a full course at the Detroit College of Medicine, and on May 24, 1907, the secretary of the college gave him a certificate stating in substance that he had passed his final examinations and would be recommended to the trustees for graduation; that on the 27th he presented his certificate to the board of medical examiners of Michigan; and that on the 30th he received from the college a diploma conferring on him the degree of doctor of medicine. The respondent board contended that he had not received a diploma at the time he presented himself for examination before the Michigan board, and that the act of that board in subsequently admitting him to practice adopted a standard less than that required by the laws of California, which justified a refusal to issue the reciprocity license applied for. The sole question presented here was whether or not the petitioner in legal contemplation was possessed of a diploma from the medical college at the time he was permitted to take his examinations before the Michigan board.

If the act of the board of medical examiners of Michigan permitting him to take the examinations before his diploma could be actually made out and issued to him constituted the maintaining of a standard not equal to that of California, then the petitioners was not entitled to the relief sought. If, on the other hand, the possession by him of the certificate and the subsequent issuance to him of his diploma was to all legal intents and purposes the possession by him of a diploma, then it was conceded that the petitioner was entitled to a license on reciprocity, and it should be issued to him. To state the question was to answer it. The certificate was to all intents and purposes the equivalent of a diploma. It certified that the petitioner had passed his final examinations, and he was therefore entitled as a matter of right to a diploma. Moreover, the diploma was in fact issued to him before he was granted his license. To say that under such circumstances he was not possessed of a diploma entitling him to take his examinations would be to put a narrow construction on the California statute, which requires the filing of a diploma prior to the taking of examinations. The statute should receive a reasonable construction, and the spirit and reason should prevail over the letter. This court is therefore of the opinion that the petitioner was entitled to the relief sought.

While, ordinarily, the action of an officer clothed with a discretion is not reviewable if exercised on matters left to his discretion, yet where the discretion is abused and made to work injustice, it may be controlled by mandamus. In this case this court thinks that the board acted arbitrarily and abused its discretion. Therefore, let the writ issue.

Neurasthenic Condition Due to Injury Compensable

(Rialto Lead & Zinc Co. et al. v. State Industrial Commission et al. (Okla.), 240 Pac. R. 96)

The Supreme Court of Oklahoma holds that, under the workmen's compensation act, an employee who had sustained an injury arising out of and in the course of his employment was entitled to compensation for partial disability where it appeared that at the time the question was being considered he was probably not suffering with physical disability, but had neurasthenia which had its origin in the accidental injury, and was unable to work at his former occupation, but was able to do lighter work for which he received about one-half the wage that he had previously earned. The court says, after noting that it had been stated that it had never passed on the question of whether a neurotic whose trouble has its origin in an accidental injury is entitled to compensation, that it does not hesitate to say that when a mental condition comprehended under the term of "neurasthenia" is shown by competent evidence to exist as a direct result of a physical injury sustained by an employee, arising out of and in the course of his employment, which condition deprives the employee of working in his former occupation, the same would be compensable under the workmen's compensation act of Oklahoma. It is well settled by a long line of English decisions, based on workmen's compensation acts, that, where neurasthenia intervenes after an accident and produces incapacity, to entitle the workman to compensation for an accidental injury the preceding injury must be shown to be the proximate cause of the neurasthenic condition.

In other words, this court holds, as it restates it, that where, as the approximate result of an accidental personal injury sustained by an employee arising out of and in the course of his employment, such employee, after all objective and subjective symptoms of actual physical injury are removed, suffers from a nervous breakdown and a neurasthenic condition ensues attributable to such injury which precludes the employee from resuming his work in his former occupation, such mental condition is an injury arising out of and in the course of his employment and is compensable under the provisions of the workmen's compensation act.

Health Officer and Commissioners Must Act Together

(Eckles v. Board of County Commissioners of Hughes County (Okla.), 239 Pac. R. 567)

The Supreme Court of Oklahoma, in affirming a judgment for the defendant, says that the plaintiff sought to recover on two itemized accounts for services and expenses in treating smallpox in 1921 and 1922, and that the question involved in this appeal was the legality of claims and expenditures for him as county superintendent of public health beyond the amount of the estimate approved by the county excise board. Under section 8680 of the compiled statutes of 1921 of the state, the compensation to be allowed the county superintendent of public health is fixed and limited to $5 a day for the time actually and necessarily served, and not exceeding the sum total of a certain amount yearly according to the population of the county, and any other compensation allowed is by contract for actual and necessary expenses, in the discharge of his duties, in carrying out the "provisions, rules and regulations" promulgated by such health officer and the board of county commissioners for the suppression of dangerous epidemics in the county. The compensation for expenses provided in the last paragraph of the section for the suppression of dangerous epidemics is not in the nature of an involuntary indebtedness but is voluntary, and grows out of a contractual relation, and any claim not contracted under this provision is illegal and void. Whatever the emergency on account of a dangerous epidemic, the county superintendent of public health and the board of county commissioners are required to act together in formulating such "provisions, rules and regulations," as may be necessary to prevent the spread of the epidemic, and they are given full power to compel submission to their rules and regulations to stamp out or prevent the spread of the epidemic.

The evidence in this case did not show any concert of action on the part of the health official and the county commissioners. Whatever rules and regulations were made were made by the superintendent of health, and the county commissioners passed no resolution and took no action in the matter. But section 8680, in providing for the payment of actual and necessary expenses, requires that they must be such as were contracted for in the discharge of the health official's duties in the emergency. The evidence must show a contractual relation between the parties, there must be rules and regulations agreed on in fixing the duties of the health officer, and there must be a promise to pay for services and expenses incurred. The evidence in this case failed to show any compliance with the statute in these respects. Furthermore, this court cannot see anything mandatory in these provisions of the statute even in the case of an emergency. It is discretionary with the county commissioners as to whether they take any action or not, even if a dangerous epidemic does exist. If they do act, and, with the superintendent of health, make rules and regulations to meet the danger, even then they cannot contract for expenses beyond the resources of the county and the constitutional limitations of indebtedness. If within such limits, the contract will be legal; otherwise, illegal and void. Wherefore the court is of the opinion that the judgment rendered for the defendant was correct and should be affirmed.

Malpractice Where Radium Copsule Was Swallowed

(Jacobs v. Grigsby et al. (Wis.), 205 N. W. R. 394)

The Supreme Court of Wisconsin, in affirming a judgment for $3,000 damages in favor of the plaintiff, says that one of the defendant copartners used a silver capsule containing radium in treating the plaintiff for a nasal trouble. He first treated the left nostril, but while he was packing the capsule in the right nostril the capsule slipped away from him, dropped into the plaintiff's mouth, and was swallowed. In order to prevent serious injury to the plaintiff by reason of the capsule being swallowed, an operation was immediately performed, and it was for the pain and suffering and damages resulting from that operation that the plaintiff brought this action for malpractice, contending that the physician was negligent because he used too short a string attached to the capsule. It was undisputed that when he treated the left nostril the capsule had attached to it a string 5 or 6 inches in length, but the plaintiff contended that in cutting off the gauze which was used in the packing the physician also cut off the string to a length not exceeding a couple of inches. On behalf of the defendant, it was contended that a string of the ordinary, usual length of 6 or 6½ inches was used. The jury found by a special verdict, the form of which was agreed on by both parties: (1) In giving the plaintiff's right nostril the treatment in question the defendant failed to have attached to the radium capsule a string of the usual and customary length usually employed by physicians in good standing of the same school of medicine and surgery in that city and similar localities, under like or similar circumstances, having due regard to the advanced state of medical and surgical science at the time; (2) such failure to use a string of the usual and customary length attached to the capsule was the proximate cause of the capsule slipping down the plaintiff's throat; (3) the defendant ought, in the exercise of that degree of care and skill usually exercised by physicians in good standing of the same school of medicine and surgery in that city and similar localities, under like or similar circumstances, having regard to the advanced state of medical and surgical science at the time, reasonably to have anticipated that an injury to the plaintiff would be the natural and probable consequence of the failure to use a string of the customary and usual length; and (4) damages in the sum of $3,000.

The questions that controlled this case were: (1) What was the length of the string used by the physician? (2) What is the customary length of string used for the purposes for which this was used? and (3) Could the jury reasonably find that a string not to exceed 2 inches in length was the proximate cause of the injury to the plaintiff? On the question of the length of the string, the testimony was in sharp conflict. The physician who performed the operation to remove the capsule from the plaintiff's stomach testified that the string was 6½ inches in length; that he measured it after removing it. The defendant physician testified that the string was 6¼ inches in length, and that he also measured it after its removal from the stomach. The plaintiff testified that the string was lying on the table after the treatment of the left nostril and that it was only about 1½ inches in length. Two nurses testified that the string was not more than 2 inches long. On this state of the testimony it could not be said that the verdict was without evidence to support it. The length of the string was peculiarly a question for the jury to decide on the conflicting testimony. It was somewhat significant that the string was not produced on the trial. Why it was not the court was not advised.

The testimony of the physician that he used a string about 6½ inches long, and that he followed the usual and customary practice in all that he did, sufficiently established the fact by expert testimony that a string for such a purpose is customarily of a length of about 6½ inches. The contention that the jury could not say that the shortness of the string was the proximate cause of the capsule falling into the plaintiff's mouth and being swallowed was not tenable. The physician testified that he knew the capsule might pass down the nasal passage into the mouth. Knowing that, it seems to the court he should have known that a string only 2 inches long was too short safely to prevent the capsule from so doing. At least the court cannot say that twelve men might not reasonably come to such a conclusion. Nor can the court disturb the verdict as excessive, when, after more than two years, the plaintiff was still suffering more or less pain, probably due to adhesions.

Blastomycosis Resulting Naturally and Unavoidably

(United States Casualty Co. v. Smith (Ga.), 129 S. E. R. 880)

The Court of Appeals of Georgia, Division No. 2, in affirming a judgment which denied the insurance carrier's appeal from an award of compensation under the workmen's compensation act, holds that the industrial commission was authorized to find that the employee was suffering from the disease of blastomycosis, and that it resulted naturally and unavoidably from his original injury. He had had, from a scald, a blister about the size of a nickel form on the back of his neck, which blister was burst and became a sore, a month or so after which the wound was exposed to ammonia gas which enveloped him. He soon began to experience pains in one of his arms; after about two months was never able to work again; at the end of about a year had to have an arm amputated; and four months afterward was informed by a specialist in skin diseases that he was suffering from blastomycosis, a disease caused by a vegetable germ or fungus.

There are decisions which might be construed as holding that the contention of the employee in a case of this sort would not be established in the absence of evidence to show when, where or under what circumstances the germ made its entrance into his person. But, after mature deliberation, this court is unwilling to apply such a rule in this case. The statute, in providing that the disease must have resulted naturally and unavoidably from the accident, does not, this court takes it, abolish the well established proximate cause doctrine, but does define it, the court thinks, so far as it relates to diseases, in compensation cases. The definition, however, does not appreciably change the general rule, and might have been inserted for the purpose of excluding diseases developing in the course of the employment, but not caused by some antecedent injury.

The word "naturally," as here employed, means according to the laws of nature or the usual course of things. It is unimportant that it is unusual for persons to be afflicted with the disease in question, provided it seized the particular person in the way usual to the disease. According to the evidence as to the character, habits and effect of the blastomycosis germ, the employee's contracting of the disease was in accordance with its nature, and it therefore resulted naturally from the accident. Did it also result "unavoidably"? This word is to be given a reasonable interpretation, according to its general acceptation, having in mind the general requirements of the law as to the care and diligence which a person ordinarily must exercise for his own safety and protection. It is not employed in an absolute sense, and does not imply that the disease must follow certainly. A thing is generally considered unavoidable when common prudence and foresight cannot prevent it. The evidence showed that the employee consulted physicians promptly, and was constantly under treatment, and warranted the conclusion that he made every reasonable endeavor to maintain his health from the first appearance of illness. Anyway there would be no presumption of voluntary exposure or lack of care on the part of the employee. The evidence was easily sufficient to establish that he could not have avoided the disease by ordinary care. It was immaterial that neither the employer nor the employee could have known that the particular disease might result from an accident, since, in the light of modern science and common experience, it could have been reasonably anticipated that a disease of some character would probably result therefrom. The conclusion is that the award in the instant case was authorized.

City Not Liable for Gross Negligence as to Hospital

(Young v. City of Worcester (Mass.), 149 N. E. R. 204)

The Supreme Judicial Court of Massachusetts, in affirming an order sustaining a demurrer to the plaintiff's declaration, says that the plaintiff, as administrator, sought to recover for the death of his intestate, which was alleged to have been caused by a defective elevator in the Worcester City Hospital. The plaintiff very properly conceded that he had no right to recover in damages for the death of his intestate caused by the negligence of the municipality's agents or servants. The maintenance of the hospital by the defendant, while permissive, is a matter of public service conducted exclusively and purely for the general and common good. In some cases the statutes enjoin such service on cities and towns, and in others permit it. When such service has been entered on, there is no good reason why a liability to private action should be imposed when a town or city voluntarily enters on such a beneficial work, and withheld when it performs the service under the requirements of an imperative law. The plaintiff, however, contended that there is a distinction between gross negligence and negligence, and that the admission of gross negligence by the demurrer removed this case from the field covered by the decisions. But the principle which exempts municipalities from responsibility for injuries received in consequence of a negligent or defective performance of a public service is of equal pertinency when the negligent act is greater in culpability than is ordinarily imputed to negligent conduct.

Roentgenograms May Be Used to Refresh Recollection

(Hinkelman v. Pasteelnick (N. J.), 130 Atl. R. 441)

The Supreme Court of New Jersey, in affirming a judgment in favor of the plaintiff for damages for personal injuries, says that the only ground on which a reversal was sought was an alleged error on the part of the trial court in permitting a physician, who was the plaintiff's physician and attended her in the hospital, to look at a roentgenogram, which he was unable to say was a photograph of the plaintiff's leg after her injury, and to testify that an inspection of the plate refreshed his recollection as to the condition of the bones of the plaintiff's foot. The testimony was objected to on the ground that it was improper to permit the physician to refresh his recollection by the use of a photograph that he could not swear was taken of the plaintiff's foot or leg. But the supreme court thinks that the objection was without merit. Anything that will refresh the recollection of a witness may be looked at by him for that purpose, although in itself it is not evidential.

West Virginia State Medical Association, Morgantown, May 25-27. Mr. S. O. Neale, 211 Smallridge Building, Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

31: 151-313 (Feb.) 1926

*Hookworm Infestation and Physical Condition of School Children. W. G. Smillie and D. L. Augustine, New York.—p. 151.
*Fasting as Cause of Convulsions. H. Josephs, Baltimore.—p. 169.
*Intracutaneous Tests with Human and Bovine Tuberculin. H. F. Downing and H. L. Higgins, Cincinnati.—p. 178.
*Acute Pyogenic Arthritis of Hip Joint in Infancy and in Childhood. M. P. Cooperman, Philadelphia.—p. 183.
*Coarctation of Aorta: Case. J. W. Bruce and R. Ball, Louisville, Ky. —p. 196.
Chylomicron (Free Fat) Content of Blood in Infants. L. C. Schroeder and E. Holt, New York.—p. 201.
*Index of Refraction of Breast Milk Serum. C. I. Solomon and A. T. Shohl, New Haven, Conn.—p. 218.
*Basal Metabolism After Pneumonia. B. Shick, P. Cohen and I. Beck, New York.—p. 228.
*Trypsin Secretion of Infants. T. Lukacs, Szeged, Hungary.—p. 235.
*Hexylresorcinol in Treatment of Pyelitis of Infancy and of Childhood. W. J. Scott and V. Leonard, Baltimore.—p. 241.
*Polyarthritis in Infant Six Days Old. L. F. Richdorf and W. H. Griffith, Minneapolis.—p. 250.
*Congenitally Acquired Pyelitis. C. E. Conrad, Harrisonburg, Va. p. 254.

Hookworm Infestation of School Children.—Nearly 2,000 children were examined by Smillie and Augustine for hookworm and to determine what effect, if any, its presence had on growth. It was found that heavy hookworm infestation (500 *Necator americanus* or over) causes marked retardation in the normal growth in height and weight and lowers the hemoglobin of children of school age. Light hookworm infestation (from 1 to 100 *Necator americanus*) produces no measurable retardation in the normal development of children of school age, nor is the hemoglobin of this group reduced to a measurable degree. An infestation of twenty-five *Necator americanus* may be considered as the economic base line of cure. An infestation of twenty-five worms or less represents a carrier state, and is not true hookworm disease. Sanitation and education should be relied on to control the hookworm carrier. Hookworm treatment should be used only in cases of hookworm disease.

Fasting as Cause of Convulsions.—Attention is called by Joseph to short fasting periods as a cause of convulsions in children, especially that type of convulsion which is seen at the onset of acute infections. Studies carried out on several of the children who came under observation indicate that these convulsions are probably of hypoglycemic origin. Attention is called to the close association of this type of convulsion with attacks of recurrent vomiting. Ten cases are reported.

Intracutaneous Tuberculin Tests.—Experience in making routine skin tests with human and bovine tuberculin has convinced Downing and Higgins that both bovine and human tuberculin should be employed in routine tuberculin tests, not only to determine the diagnosis of the type of tubercle bacilli present but also to increase the value of the test by detecting cases which would otherwise be missed. In their series, the missed cases would have amounted to 15 per cent of the total tuberculous patients. Evidence from two cases tends to confirm earlier reports that in the first stages of tuberculosis the patient will react to only one type of tuberculin, presumably that of the infecting type, while later the patient reacts to other types (group reaction).

Infectious Arthritis of Hip Joint in Children.—Cooperman summarizes his observations as follows: acute gonococcus infections of the hip joint in the new-born are characterized clinically by early spontaneous dislocations. Immobilization in plaster casts and diathermy are of definite curative value in preventing destruction and relieving the inflammatory reactions. Reduction of the dislocation should be attempted during the acute stage. Vaccines have proved valueless. Streptococcus and staphylococcus infections of the hip joint in older children are characterized by severe constitutional and local reactions. Destruction of the joint is induced by unallayed muscle spasm and extension of the disease through contracting pressures. Incision and drainage and extension and fixation relieve symptoms and prevent progressive destruction of the joint. Intravenous therapy has proved of little value. Children who have recovered from the acute infections should be under observation for at least one year. Deformities frequently have to be corrected or pathologic dislocations reduced.

Coarctation of Aorta.—A case of coarctation of the aorta of the congenital or infantile type is reported by Bruce and Ball. The clinical manifestations were similar to those of intracranial injury caused by birth trauma—intermittent periods of cyanosis, irregular respirations and convulsions.

Index of Refraction of Breast Milk Serum.—A method of determination of the index of refraction of breast milk serum is proposed by Solomon and Shohl by which the addition to breast milk of 11 per cent of water and 20 per cent, or more, of cows' milk may be detected simply, rapidly and accurately.

Basal Metabolism After Pneumonia.—A postinfectious metabolic study was made by Shick, Cohen and Beck in twenty-one cases of pneumonia. There was not infrequently a low basal metabolism which rose to normal in from one to three weeks, occasionally longer, and which was associated with a slow pulse rate. Less frequently, there was a high postinfectious basal metabolism which declined to normal in from two to three weeks.

Trypsin Secretion and Rickets.—Lukacs' work thus far indicates that there seems to be a possibility of a pathogenic relationship between the increased trypsin secretion and some symptoms of rickets.

Hexylresorcinol in Pyelitis.—On the basis of clinical experience with hexylresorcinol in the treatment of pyelitis in children, Scott and Leonard believe that it is at times a distinct addition to therapeutic measures. The striking improvement in the general health and nutrition, frequently observed in children taking hexylresorcinol, does not seem to be entirely dependent on the control of the urinary infection, for it may occur long before there is any noticeable improvement in the local condition and is sometimes the most impressive effect of the treatment. To obtain the best results, treatment should be persistent; the fluid intake should not be increased, and soda should be avoided during the administration of the drug.

Polyarthritis of Intra-Uterine Origin in Infant.—In the case reported by Richdorf and Griffith, the sequence of the appearance of the disease, first in the mother and then in the child, the exclusion of chronic and secondary arthritis by clinical and laboratory methods, the presence of a similar *Streptococcus viridans* in the mother's blood and baby's joint fluid, and the absence of local signs indicating a portal of entry after contact or other infection, point toward an intra-uterine infection of the infant through the placenta by the organisms circulating in the mother's blood.

Congenital Acquired Pyelitis.—Three cases, all occurring in girls, are reported by Conrad. In two of the infants, the mothers had had pyelitis during pregnancy. In one of these two cases the mother had had such severe pyelitis that it was necessary to have her in the hospital for treatment during the fifth month of pregnancy. Two of the infants had convulsions, which were quite severe in one. Two of the infants recovered, and the third was much improved when last seen.

Heart Disease and Life.—Roberts believes that a commission to study the rheumatic group of diseases over a period of years is necessary. This will include a field force to study weather, housing, climate, heredity, environment, exposure, air and clothing; and a laboratory study to determine the bacteriology and the conditions of infection. The education of the public on the frequency of heart disease and how the individual ought to live is an important factor. The public is entitled to a public meeting by every medical society. The physician has no right, as a medical leader in his community, to live contrary to the dictates of preventive medicine. Example is greater than precept, and self-denial than self-indulgence. There should be an annual physical examination, not only of the layman, but of the physician himself. The examination should be done at home by a clinician with the clinician's point of view and experience. The local medical society might well have itself examined annually as a form of both wisdom and example.

Pellagra and Chronic Ulcerative Colitis.—Barnes' case yielded nothing new as far as any specific pathologic condition is concerned. The general pathologic findings were identical with those described in other well-studied cases of typical pellagra, but the marked degenerative changes in the central nervous system emphasized by some writers were not present. No evidence of a polyneuritis was found. From the standpoint of etiology, if any one pathologic condition found in this case might be regarded as having some etiologic significance, it would seem to be a severe colitis, which was the earliest, the most constant and most important clinical symptom and, aside from the cutaneous lesions, the most striking pathologic finding. The histologic picture was identical with that of a severe chronic bacillary dysentery, but bacteriologic studies were negative as to the presence of dysentery bacilli.

Nasal Ganglion Injection Controls Asthma.—Gundrum's case was one of so-called inherited or familial asthma. The duration of the asthma was twenty years and of the eczema ten years. The asthma and eczema were controlled by cocainization of the sphenopalatine ganglions but returned as soon as the effects wore off. Injection with 5 per cent phenol in 95 per cent alcohol has up to the present time given complete relief.

Specific Antigen Injection in Asthma.—Twenty-one patients suffering from asthma had pathogen-selective cultures made by Solis-Cohen and Rubenstone from various portions of the upper respiratory tract. Thirteen different micro-organisms grew. *Micrococcus catarrhalis* was present in every case but one. Only one third of the organisms that grew on Löffler's medium also grew in the patient's whole blood. It would seem, therefore, that these asthma patients harbored twice as many organisms that were nonpathogenic for them as organisms that were pathogenic. Such bacterial infection can be overcome only by the restoration of sufficient bactericidal or bacteriostatic power to the patient, which in the markedly lowered resistance of most asthmatic patients can best be aided by the proper injection of the specific antigen required, after recognizable diseased tissue has been removed. The specific antigen may be lacking in vaccine as ordinarily prepared, as the organisms predominating on ordinary culture mediums may be nonpathogenic for the patient, while in such culture the etiologic organism may fail to grow or may be present in comparatively small numbers. The pathogen-selective method of culture picks out the organisms that are pathogenic for the patient and exaggerates their growth, while inhibiting the growth of or destroying organisms that are nonpathogenic for him. Specific vaccine is of maximum efficiency when made chiefly from those organisms which on pathogen-selective culture grow well in the patient's whole, coagulable blood. To be administered properly, the dosage of vaccine should be regulated according to the general, focal and local reactions produced.

Ventricular Tumor Causes Sudden Death.—Shuman has seen two cases of tumor of the fourth ventricle, both in women, aged 29 and 30, respectively, who died suddenly, in the early morning, the only pathologic change of importance shown at necropsy being the ventricular tumor. In both cases symptomatic relief had been obtained by the injection of one-fourth grain (0.016 Gm.) of morphine sulphate some hours previously. One of these tumors was a cyst, the other an ependymal blastoma.

Secondary Carcinoma of Heart.—An unusual case of carcinoma of the heart, secondary to that of the breast, is reported by Kapsinow. The distribution indicates that the growth was a retrograde invasion by direct continuity along the lymphatic channels.

Ulcers and Cancers in Scar Tissue.—Four cases of ulceration occurring in the cicatrix of extensive burns are recorded by Johnson. Of these, three were proved microscopically to be squamous-cell carcinoma, while the fourth was benign in character but clinically precancerous.

Tuberculosis of Breast.—Hinton and Lawson analyze eight cases. The chief point of interest in the history of this condition is pain which was present in five of the eight patients. On physical examination, the five complained of tenderness over the enlargement, which is not usually encountered in cases of malignancy. The axillary lymph glands were found enlarged in three cases. There was little difference in the sides involved, the right side being affected in five cases and the left in three. The nipple was retracted in one case. The authors did not find the typical "pig skin" appearance over the tumor, which is frequently described. The Wassermann reaction was negative in all cases. A history of trauma was obtained in one case. Physical examination of the chest revealed râles in two cases. Evidence of a previous cervical adenitis was found in two cases. The family history of tuberculosis was negative except in one case. One patient gave a history of having had a dry cough for approximately eight years, without expectoration.

Tuberculosis of Mammary Gland.—Ten cases of mammary tuberculosis, observed in a series of 671 breast cases are reported by Shipley and Spencer. In one case there was a family history of tuberculosis. In one case there was a history of trauma. In five cases there was clinical evidence of preexisting tuberculosis elsewhere. There was an involvement of the cervical lymph nodes in one case and of the axillary nodes in six cases. The lesion was always unilateral, with involvement of the right mammary gland in seven cases, and of the left in three. The lesions were single in five cases, multiple in two, and diffuse in three. The portion of the breast involved was very irregular. There was skin ulceration in three cases, retraction of the nipple in two cases, discharge from the nipple in one, and sinus formation in one. The preoperative diagnosis was tuberculosis in four cases, chronic mastitis in one, and carcinoma in five. There were no deaths in the series.

Persistent and Recurrent Hyperthyroidism.—Following subtotal thyroidectomy, persistence of symptoms of hyperthyroidism, together with persistence of a basal metabolic rate above normal, according to Lahey and Clute, indicates that there still remains a segment of hyperfunctioning gland capable of producing hyperthyroidism. Removal of a very large proportion of this segment by reoperation will, in a majority of instances, bring about a cure. The administration of compound solution of potassium iodide in these cases, even over a period of months, has failed to produce a single cure. The essential factor in the reoperation of these cases is the separation and retraction of the internal jugular vein and the common carotid artery from the thyroid remnant. With this done, any amount of thyroid tissue desired may be removed from the thyroid remnant. Forty-eight patients were seen by the authors.

Osteomyelitis of Sternum.—Wilensky and Samuels report four cases and give a résumé of twenty cases already on record. Among eleven cases, the mortality was 27 per cent.

Etiology of Postoperative Pulmonary Abscess.—Experimental and clinical observations lead Holman to conclude that postoperative pulmonary suppuration probably has its origin less often in the aspiration of blood and mucus than in the setting free of a septic embolus into the blood serum.

*Psychiatric Value of Kuhlmann Tests. J. S. Plant, Newark, N. J. —p. 253.

Sarcomatosis of Brain.—Fried relates the case of a man, aged 33, who suddenly became ill with symptoms of a brain tumor, which could not be localized. He died two months after the onset of the first symptoms; necropsy showed to the naked eye merely a small tumor nodule, but the microscope revealed the widespread presence of tumor cells throughout the entire cerebrum, cerebellum, pons, medulla oblongata and meninges. The growth proved to be composed of small, round cells which showed numerous mitotic figures, and had a perivascular arrangement. The parenchyma and interstitial tissue of the brain showed extensive secondary degenerative changes. Fried is of the opinion that the tumor originated from the adventitial cells of the Virchow-Robin spaces, in other words, from the mesenchymal element of the brain, and it therefore is regarded as a primary sarcoma of the connective tissue of the brain.

Parkinsonian States.—Four cases are reported by Hassin and Bassoe. One was a case of postencephalitic state in a syphilitic patient; one a similar condition following a head injury in a child; one a case of genuine paralysis agitans and one a parkinsonian state in acute epidemic encephalitis. In all four cases, the clinical picture presented features of parkinsonism. In none was the pyramidal system affected, but the changes more or less diffusely involved the basal ganglia and the substantia nigra. In the third case (paralysis agitans), the changes were degenerative only, while in the others—all cases of postencephalitic parkinsonism—they were both degenerative and inflammatory, although the duration (three years) was practically the same in the first three cases. In the authors' opinion it is, therefore, not proper to look on paralysis agitans as an end-result of encephalitis, nor to consider it an equivalent of a postencephalitic syndrome.

Psychoses Occurring During Pregnancy.—Fifty instances *of psychoses associated with or following childbirth are dis*cussed by Strecker and Ebaugh. The diagnoses were: manic depressive, 18 cases; toxic exhaustive, 17; dementia praecox, 13; general paralysis, 1, and psychoneurosis, 1, thus clearly establishing the fact that any psychosis may follow childbirth. Hence, the term "puerperal psychosis" does not represent a clinical entity and should not be used.

Psychiatric Value of Kuhlmann Test.—A new age level scale of tests devised by Kuhlmann is described. The results from testing fifty-three children indicate that definite emotional disturbances are with large precision detected through using the Kuhlmann and Terman scales, in such a way as to evaluate the "mental control" element in the former scale.

Serum Calcium in Experimental Hypocalcemia.—This investigation by Moritz indicates that in a general way a decrease in serum calcium, such as occurs following thyroparathyroidectomy, shows a disproportionately great decrease of the diffusible fraction But in an increase in serum calcium produced by injection of parathyroid extract (Collip) the ratio of the two did not show consistent changes.

Blood Changes During Digestion.—The experimental results presented by Morgulis furnish evidence that, during the absorption of protein digestion products, the urea nitrogen of the systemic blood frequently increases before the amino-acid nitrogen Not infrequently a fall in the amino-acid nitrogen of the blood has been found in the early stages of the digestive process. Morgulis believes that these experiments furnish proof of the urea-forming function of the liver in the intact animal.

Antirachitic Properties of Hays.—Steenbock et al. assert that antirachitic properties of hays are related to their exposure to sunlight. Clover hay made with exposure to sunlight showed considerable calcifying power, while the clover hay made in the dark was inactive. Direct irradiation of a milking goat with ultraviolet rays brought about a positive calcium balance even when the animal was receiving the weathered clover, which by itself had no beneficial effect.

Raising Antirachitic Properties of Cow's Milk by Irradiation.—By exposure to the radiations of a quartz mercury vapor lamp, the antirachitic properties of cow's milk were increased eight or more times. Under the same conditions a sample of goat's milk was increased in activity about twenty-four times. This increase in activity can also be induced rather promptly, though to a lesser degree, by direct irradiation of the animal. Attention is called by Steenbock et al. to the beneficial results to be expected from this by dairymen

Antirachitic Substances.—Results reported by Bills are, that antirachitic vitamin in cod liver oil was destroyed by *n*-butyl nitrite, slowly at room temperature, and rapidly on heating Some seal oil was found to be inactive, but irradiated cholesterol dissolved in the seal oil was moderately antirachitic. When the irradiated cholesterol was dissolved in cod liver oil and heated with *n*-butyl nitrite, the antirachitic activity was destroyed. These reactions support, but do not prove, the hypothesis that the antirachitic vitamin is identical with the antirachitic derivative of cholesterol produced by irradiation.

Action of Acids, Alkalis and Enzymes on Insulin.—Shonle and Waldo conclude that insulin may be of a true protein structure possessing specific physiologic activity or it may consist of a chemical complex attached to a protein structure However, when the protein is broken down into slightly smaller units, by either acid, alkali, or enzyme, the physiologic functioning is lost.

Retention of Uric Acid During Fasting.—Measurements made by Lennox of uric acid in blood and urine during twenty-one fasting periods revealed the fact that variations in excretion of uric acid following the use of various purine-free diets do not mean variations in production, but variations in the amounts of uric acid contained in blood and tissues. The observations suggest the use of a low fat diet in the treatment of gout. Disturbance in kidney function and in metabolism of the body both played a part in the retention. Of various possible factors examined, the attending ketosis seemed the most constant. It is probable that various interrelated disturbances in oxidation and in the acid-base equilibrium of the blood and body tissues are involved.

Effect of Vitamin A Deficiency on Nitrogen Metabolism.—A theory is advanced by Morgan and Osborn to account for the differences between the excretion of allantoin and uric acid in normal and vitamin A deficient animals. It is suggested that in the absence of vitamin A, the animal organism fails to produce purine-containing compounds from the ordinary sources, perhaps arginine and histidine, but continues to utilize over again such portions of discarded purine ring-containing substances as are ordinarily excreted in the form of allantoin. The portions of these compounds which are oxidized only to uric acid are apparently no longer usable and continue to be excreted in proportion to the amount of destruction of cellular material in vitamin A deficient animals in the same manner as in normal animals.

Ultraviolet Irradiation of Hen Affects Vitamin Content of Hen's Egg.—It is asserted by Hughes et al. that the amount of ultraviolet irradiation which a hen receives is an important factor in determining the antirachitic vitamin content of the eggs which she produces when her feed is low in the antirachitic vitamin. Eggs which have a low antirachitic vitamin content do not have as high a hatchability as eggs having a high antirachitic vitamin content, other factors influencing hatchability being constant.

Effect of Excessive Calcium Ingestion.—Denis and Corley present evidence to show that rabbits receiving a daily dose of calcium chloride or calcium lactate showed no higher calcium content of the tissues than did the control animals. Daily exposure to ultraviolet rays from a mercury tungsten arc was also without effect on the calcium content of the tissues and serum.

Determination of Energy Value of Foods.—A method has been developed and tested by Benedict and Fox for the indirect determination of the energy values of foods, feeding stuffs and excreta. The functional principle involves the direct measurement of the oxygen consumed during the combustion of a known weight of a substance and the computation therefrom of the potential energy of the substance by means of a series of factors for the calorific value of a liter of oxygen previously established with a bomb calorimeter. The apparatus embodying this principle has been styled the "oxy-calorimeter."

Excretion of Normal Urine Sugar.—Experiments made by Blatherwick et al. show that the addition of glucose to a standing diet causes an increased excretion of fermentable sugar without any significant change in the nonfermentable fraction. These results indicate the chief source of the fermentable sugar to be the main carbohydrate metabolism. The nonfermentable reducing substances appear to be largely dependent on the protein metabolism.

Effect of Ingestion of Orange Juice.—A study was conducted by Chaney and Blunt on two growing girls, aged 10 and 11, respectively, to determine the effect of orange juice on calcium, phosphorus, magnesium and nitrogen metabolism. Calcium assimilation was decidedly benefited when oranges formed a part of the diet, the increased retention being considerably greater than the calcium added in the oranges and greater than might be expected from a stimulus to retention caused by a larger calcium intake. The increase in phosphorus retention was even more marked than that of calcium, more than three times as much phosphorus both in grams and percentage of intake being assimilated when orange juice was added. The magnesium retention was also increased, although to a less marked extent than that of calcium and phosphorus. Nitrogen assimilation was greater when orange juice was ingested, even though the nitrogen intake was not altered. Urinary ammonia was decreased, and urinary p_H and organic acids increased. The increase of organic acids amounted to approximately 7 per cent of the citric acid of the orange juice ingested. A marked increase in the children's weight was observed.

Maintenance Values of Certain Proteins.—The evidence presented by Rose and MacLeod indicates that the nitrogen balance can be maintained with milk, meat, or white bread and milk in amounts to contribute each half of the protein, with a protein intake which is not more than 85 per cent of the average maintenance requirement of adults, but that the efficiency of meat is slightly less than that of milk or bread and milk.

*Nuclear Inclusions in Testes of Monkeys Injected with Tissue of Human Varicella Lesions. T. M. Rivers, New York.—p. 275.

Relation of Bacillus Abortus from Bovine Sources to Malta Fever.—Two cultures resembling *Bacillus abortus* from cattle, isolated by Smith from human cases of so-called Malta fever, are shown to be in their effect on guinea-pigs not identical with the bovine strains. The results of studies of *B. abortus* from swine indicate a close relation between the porcine strains and the two human strains.

Agglutination Affinities of Abortus-Melitensis Group of Bacteria.—The conclusions drawn by Orcutt from this study are that, while there appears to be evidence of serologic distinctions between *B. abortus* and *B. melitensis* cultures as studied by earlier workers, her experiments show no serologic distinctions among the six strains used in the study. *B. melitensis* II and *B. melitensis* III were found identical with the bovine and swine strains by means of agglutination and agglutinin absorption reactions in unheated serums, by agglutination in heated serums, and with the use of heated cultures in unheated and heated serums.

Origin of Lepra Cell.—By means of the method of vital staining, Oliver found that the lepra cell in rat leprosy is derived from the histocyte. From the similarity in morphology and function of the lepra cells in this condition and those of human leprosy, it seems likely that derivation of the cells in the two conditions is similar.

Nuclear Inclusions in Varicella Lesions.—Eosin-staining nuclear inclusions resembling those deemed characteristic of a certain well known group of filtrable viruses, among which is varicella, were found by Rivers in vervets' testes inoculated with emulsified tissue of human varicella lesions.

*Pupils in Somatic and Visceral Disorders in Association with Referred Pain and Hyperalgesia. J. Byrne, New York.—p. 105.
*Dementia Praecox in Identical Twins. G. H. Parker, Cambridge, Mass.—p. 135.
*Four Cases of Spinal Cord Compression. S. Rothenberg, Brooklyn.—p. 143.

Pupils in Somatic and Visceral Disease.—As the result of his observation, Byrne urges that the study of the pupils in association with referred and reflected pain and hyperalgesia should be made an integral part of all routine physical examinations. Byrne avers that the areas of reflected pain and hyperalgesia described by Head require revision and amendment, and the Dejerine or Klumpke-Dejerine sign in injuries of the spine about the thoracicocervical junction needs reevalution.

Dementia Praecox in Twins.—The conclusion is reached by Parker that dementia praecox is germinal in origin; that it is a mendelian recessive as compared with the normal state. The occurrence of this disease in one of a pair of twins should lead the attending physician to an immediate examination of the other twin.

Spinal Cord Compression.—Significant in the symptomatology of the four cases reported by Rothenberg was the rapid development of the compression, and the infrequency of pain as a prominent symptom. The compression in these cases was due to: osteomyelitis, *Cysticercus cellulosae* infectoin, endothelioma and Hodgkin's disease.

Bacterial Cystitis in Female. W. T. Briggs, Lexington, Ky.—p. 209.

Effect of Diuretics on Transplanted Kidneys.—A series of experiments was performed by Holloway on dogs in an attempt to determine the effect of diuretics, injected intravenously, on autogenous and homogenous kidney transplants. The functional activity and also the secretion of autogenous transplants are apparently similar, if not identical, to those of a normal kidney. The effect of diuretics is the same as on a normal kidney. Viability is maintained indefinitely, likewise function. Homogenous transplants maintain only a transient viability, and their functional activity is usually short-lived. As long as homogenous transplants remain viable, they function in a manner similar to autogenous transplants. They tend to eliminate urine which in most respects is similar to urine secreted by normal kidneys. As a rule, however, the early appearance of albumin, red blood cells and pus denotes marked parenchymatous changes in the kidney. While functioning, the homogenous transplant tends to respond to a diuretic in very much the same manner as does a normal kidney, except that diuresis is not so marked or so prolonged. Loss of function and lack of response to diuretics are apparently directly in proportion to pathologic changes within the transplanted kidney. When function has ceased, the introduction of a diuretic is without effect.

Etiology of Calcareous Pyelonephritis.—Hager reports a case of calcareous pyelonephritis from which he was able to isolate *Salmonella ammoniae*. The data obtained from this case agree with chemical and experimental data obtained from the study of alkaline encrusted cystitis and offer an explanation of the etiology of calcareous pyelonephritis.

Effect on Bladder of Section of Sacral Nerves.—By means of experiments on dogs, Potter shows that section of both sacral nerves does not affect the vesical tone or the mechanism of micturition; nor does it cause retention of urine or reflux up the ureter.

Cavernous Hemangioma of Bladder.—Ten cases of cavernous hemangioma of the bladder are recorded in the literature. Of these, three were confirmed by microscopic examination. Another case is reported by Katz, which was verified by necropsy and microscopic examination. Treatment is immediate operation and cauterization.

Biologic Method (Aluminum-Potassium-Nitrate Solution) of Treating Chronic Suppurations. M. Thorek, Chicago.—p. 95.

Importance of Routine Wassermann Test.—Fitz reports an analysis of the histories of 350 unselected private patients with a view to determining the occurrence of syphilis in private practice, and in order to illustrate the diagnostic importance of a routine Wassermann test. Of these patients approximately 5 per cent were suffering from some form of syphilis. An underlying syphilis was present in at least 80 per cent of the cases with strongly positive Wassermann reactions. Therefore, the Wassermann test was of great diagnostic importance.

Ureteral Stricture.—Peacock and Hain present the results of a study of 100 cases and give a synopsis of fifty cases of ureteral stricture.

Vasotomy.—Vasotomy, in Morgan's opinion, is a logical and valuable form of therapy in certain cases, especially those of recurrent epididymitis and gonorrheal arthritis, but, he says, it should be performed only by one whose technic is not only perfect but whose judgment is excellent.

Trauma and Tuberculosis of Kidney.—Two features are stressed by Howard and LeCoque in the report of their case: First, trauma appears to have been a factor in the localization of tuberculosis in the kidney, and, second, a fistula developed between the pelvis of the kidney and the skin through Petit's triangle.

*Case of Porocephalosis. D. Riding.—p. 143.

Onchocerca Volvulus Infection. — *Onchocerca volvulus* infection is common in the Konno district of the protectorate of Sierra Leone. Larvae of this parasite were found by Blacklock in the skin of 45 per cent of persons examined systematically. A definite relationship between diseases of the skin or diseases of the eyes and the infection with *O. volvulus*, as judged by the presence of larvae in the skin, could not be established. Dissection of wild insects showed: (*a*) in 780 dissections of the gut an infection of 2.6 per cent with larvae morphologically identical with those of *O. volvulus;* (*b*) in 1,320 dissections of the thorax, a larval infection of over 1 per cent.

Development of Hookworm Larvae.—The evidence presented by Maplestone tends to show that sea water and sea sand per se have no effect in preventing the development of hookworm eggs and larvae.

Porocephalosis.—In the liver of a Sudanese man who died from pulmonary tuberculosis, Riding found several encysted larvae of *Porocephalus armillatus* and also eight similar cysts in the submucosa of the duodenum. No free nymphae were noticed in the peritoneal cavity, and no encysted larvae were found in the lungs. The parasite was not the immediate cause of death; the possibility that the destructive action of the parasite in the lungs predisposed to the development of the tubercular infection was considered, although no encysted larvae were found in these organs.

Phrenic Evulsion in Pulmonary Tuberculosis.—Davies has performed phrenic evulsion twenty times: (1) For the purpose of arresting the disease, 3 times; (2) to assist in controlling disease, 4 times; (3) as an accessory during artificial pneumothorax treatment, 5 times; (4) for the treatment of symptoms, 2 times; (5) as a preliminary to thoracoplasty, 4 times; (6) as a preliminary to the radical treatment of a tuberculous empyema, 2 times.

Occupational Bursa on Tibia.—Eccles says that a dustman not infrequently has a short ladder by the side of his dust cart, and that he mounts two or three rungs of this, and then leans with the upper third of his tibia against one of the higher rungs. In the case reported, the man had an adventitious bursa on the left leg, while on the right leg the skin was roughened at the site where the intermittent pressure had been applied.

Blood Sugar Curve in Addison's Disease.—The blood sugar curve in the case of Addison's disease reported by Chapman was remarkably flat, in accordance with a raised tolerance for glucose.

Quinine Causes Urticaria.—Two cases are recorded by Hughes in one of which quinine, given in the treatment of malaria, produced a marked urticarial eruption all over the body, while in the other it aggravated a generalized urticaria already existing as a result of a malarial attack.

Pentatrichomonas Prevalent in Calcutta.—In twenty-three cases examined by Gupta the prevalent type (or genus or subgenus) of human intestinal trichomonad was *Pentatrichomonas ardin-delteili* (Derrieu and Raynaud), 1914. This confirms a previous similar finding by Chatterji (1917) and appears to afford evidence that *Pentatrichomonas* is a parasite with a tropical distribution, whereas *Trichomonas,* sensu strictum, is a parasite rather of temperate zones.

Foreign Body in Pelvis.—Nayak reports the case of a woman who consulted him for a swelling on the right side, immediately above and behind the highest point of the crest of the ilium. No information could be got regarding the previous history, so the diagnosis lay provisionally between a suppurating hematoma and a tubercular abscess of the spine pointing in the iliac region. The swelling was incised. Nearly 2 ounces (59 cc.) of curdy matter tinged with blood was evacuated; the cavity was irrigated and just before being closed was explored with the finger. The cavity was retroperitoneal and its floor was formed by the iliac bone. At the bottom, a small hard pointed object like a spicule of bone was striking against the tip of the finger. On removal this proved to be a piece of coconut broomstick, 4 inches (10 cm.) long. The patient then admitted that the piece of wood had been introduced par vaginum to induce abortion. Instead of pushing it into the uterus, she pushed it the wrong way outside of the cervix, pierced the vaginal wall and sent it right home into the right pelvic wall.

Hirudiniasis of Male Urethra.—Mitra's patient was standing knee-deep in water without any clothes on, when he noticed a leech entering his external meatus urinarius. He tried to pull it out but the leech slipped inside. From then on he was unable to pass any urine and blood dripped from his urethra. Some strong salt solution and epinephrine were injected into the bladder. Two days later the leech was passed with violent colicky pains. It was killed by the salt solution. It measured 4 inches by ½ inch; the mouth and anus were open, and dark granular blood could be pressed out of its abdomen.

Familial Telangiectasia.—The marked symptom of multiple familial facial telangiectases is epistaxis, coming from the lesions in the nose or bleeding from similar lesions elsewhere. East gives an account of a family in which eleven members in three generations were affected. Only four persons, in two generations, remained free from the disease. In a second family, fifteen out of thirty persons were affected. In a third family, mother and daughter, each an only child, were affected. The latter's five children died young but were free from the disease. The condition appears equally in males or females, but is transmitted rather more often by females. Only six of the twenty-eight cases reported by East were in males.

Operation for Carcinoma of Prostate.—The principles which underlie the operation devised by Morson differ in no material respect from Young's, except that the approach to the gland is from above—suprapubically. All the tissues which form the base of the bladder as far back as the inter-ureteric bar and the anterior wall of the rectum are removed.

Scopolamine-Morphine Narcosis in Childbirth.—Provided that the dosage is limited to the production of amnesia only, and is adjusted to the individual, Plummer cannot see any contraindications to scopolamine-morphine narcosis in childbirth. The constant supervision that is essential makes it unsuitable, however, save in exceptional circumstances, for administration in the patient's own home. In hospitals, it is difficult to insure quiet. Full chloroform anesthesia may be given at any time for such procedures as version or rotation of an occipitoposterior presentation, the scopolamine-morphine being continued afterward, if necessary; or for a terminal forceps extraction, or perineal repair. One great advantage of this procedure is that as the mother is conserving her strength by sleeping, instead of getting worn out by repeated pains and the constant dread of more and worse ones, patients can be left much longer to Nature than would otherwise be possible; in uncomplicated cases the use of forceps merely for the mother's sake is avoided, with consequent lessened risk for mother and child.

"Lag" Glycosuria.—The chief characteristics of the "lag" type of blood-sugar curve are a rapid rise to a maximum of 0.22 or 0.23 per cent in half an hour, followed by an abrupt decline to normal. There is a concurrent glycosuria. The case described by Watson emphasizes the importance of the glucose tolerance test in throwing light on glycosurias of uncertain origin, and also suggests that cognizance should be taken of a possible relationship between the emptying time of the stomach and the distortion of the carbohydrate metabolism in cases of the "lag" type.

*Acute Nephritis in Children: Renal Efficiency Tests. R. Southby and B. L. Stanton.—p. 127.
Complete Transposition of Viscera. A. T. Edwards.—p. 133.

Acute Nephritis in Children.—Southby and Stanton analyze the histories of 103 cases of acute nephritis in children. Twenty-nine children gave a history of having had a sore throat; seventeen children had impetigo; eleven had had pneumonia; fifteen had suffered from measles; in twenty-seven, no etiologic factor was ascertainable. Of the remaining patients, two had had influenza; one had a profuse purulent nasal discharge and was suffering from scabies, with severe secondary infection of the skin. The authors assert that the majority of children suffering from acute nephritis recover completely. Diet is unimportant in influencing the total duration of the illness. Complete rest is important in the treatment.

The Lesions in Associated Tabes and Parkinson's Disease.—Marinesco reports a case of tabes associated with Parkinson's disease in a man, aged 47. Necropsy showed the characteristic lesions of tabes, in the lumbosacral region of the spinal cord. There was also considerable destruction of cells in the substantia nigra, with sclerosis and lymphocyte infiltration of the arteries; evident also in the cerebellar peduncles, less in the pons and medulla. These cerebral parenchymal and vascular lesions were similar to those in the roots and meninges of the lumbosacral region. Evidently all these lesions were caused by the same spirochete; its localization in the midbrain had entailed Parkinson's disease; while in the spinal cord it had caused tabes. In eight cases of Parkinson's disease and ten of postencephalitic parkinsonism, the locus niger was always affected. Marinesco refers to Tretiakoff who considers not only the red nucleus but also the substantia nigra as centers controlling the muscular tonus.

Is There Heredity of Tuberculosis?—Debré and Lelong assert that thorough observation, necropsies, microscopic examinations, and inoculations seem to testify that no contamination with tubercle bacilli is possible by way of the placenta; nor is there inheritance of a tuberculous soil. The doctrine of heredity of tuberculosis, they say, is based not on facts, but on impressions. They can find no evidence to sustain them.

Treatment of Fetid Respiratory Process.—Castex, Heidenreich and Repetto report a case of fetid expectoration in a man, aged 45. The clinical and roentgen ray examination indicated a cavity from gangrene of the lung, and bronchiectasis. Numerous bacilli were found in the sputum, but no tubercle bacilli. Under intravenous injections of neo-arsphenamine plus balsams, given by the subcutaneous and oral routes, the patient improved but the insupportable fetid odor accompanying the coughing spasms persisted. Then neo-arsphenamine was given by intercricothyroid injection (from 0.3 to 0.9 Gm.) in an aqueous solution; sometimes with glycerin added. This followed anesthesia of the trachea with a procain solution. The injection induced violent coughing and profuse discharge of sputum, for two hours. The fetid odor disappeared completely the next day, and no Vincent bacilli were found in the sputum five days later. The tenth day the fetid odor reappeared; then the injections were repeated, and the dose gradually increased to 0.9 Gm. A total of five injections was given at eight, ten, twelve and fifteen day intervals. The injections were borne relatively well, and the tendency to bronchorrhea was arrested by injection of morphine.

Endobronchial Inoculations and Experimental Tuberculosis.—Petit, Panisset and Kfoury induced tuberculosis exclusively of the lung in dogs and horses by inoculating the bronchi directly with the bacilli cultures or sputum from tuberculous patients. The inoculating material was introduced with a fine catheter through an opening in the trachea. The cheesy degeneration and cavity of the lung were absolutely identical with those in human tuberculosis.

The Filtrable Tubercle Bacillus and Its Passage Through the Placenta.—Arloing and Dufourt inoculated guinea-pigs with filtrates of different products from tuberculous children. The results were positive in most of the animals, thus testifying to the frequency of the filtrable tuberculous virus in children and infants. In fourteen of the sixteen positive cases there was no inoculation chancre or lesions of the glands. The animals died from progressing cachexia. Necropsy did not show cheesy degeneration, nor even tubercles but numerous acid-resisting bacilli were present in the lymph nodes. The lesions characteristic of human tuberculosis were manifest only in two instances. Gravid guinea-pigs were inoculated with the same filtrates; abundant acid-resisting bacilli were found in the lumbar gland of one fetus entering the last third of intra-uterine life. This is the first instance, they say, of transplacental transmission of the invisible tuberculosis virus of human origin. Research conducted within the last few months on dead infants or fetuses of mothers with pulmonary tuberculosis has given constantly negative results. The filtrable tubercle virus was not found in the blood from the umbilical cord, nor in the placenta.

*Hemogenia with Fatal Menorrhagia. L. Payan.—p. 233.
Epidemic of Special Type of Epidemic Encephalitis. Veillet.—p. 239.

Familial Neurosyphilis.—In Guillain, Périsson and Thévenard's case the father and mother had tabes, and their son, aged 4, presented bilateral Argyll Robertson pupil and a positive Wassermann test. They know of three similar cases; namely, Apert, Lévy-Fraenkel and Ménard's case of tabes in a girl, aged 15, whose mother also had tabes, and the father had died from general paresis. He had acquired syphilis after the birth of the child and had infected the wife, and the daughter at the age of 3. Baudouin and Lévy-Valensi reported a case in 1910 of general paresis in a youth whose father and mother had died from the same disease. In Grossmann's case (1917), the father and mother presented the Argyll Robertson pupil, and they and the four children had ophthalmoplegia interna. Evidently certain syphilis viruses do not induce skin or visceral lesions, but display a special affinity for the nervous system. This cannot be ascribed merely to a special soil or casual coincidence.

Enterococcus Pleuroperitonitis Complicating Cirrhosis of the Liver.—Dumitresco-Mante and Olinesco were treating a man with cirrhosis and ascites, and signs of chronic alcoholism, when he developed symptoms of infectious pleuroperitonitis. Examination of the effusion revealed the presence of the enterococcus. Since the blood cultures were negative, it is assumed that the coccus had invaded the organism by the intestinal route. It passed thence into the peritoneum, directly or through the biliary tract, thus causing secondary infection of the peritoneum and pleura.

Iodized Oil in Roentgenography of the Pericardium.—Castex, Carelli and Gonzalez had under observation a case of tuberculous pericarditis with hemorrhagic effusion in a young man. Roentgenograms taken after release of 300 cc. of fluid and insufflation of 100 cc. of air revealed considerable thickening of the parietal pericardium, and that the shape of the cardiohepatic angle was an acute angle. A light area between the right edge of the heart and the pericardium suggested the presence of adhesions. After injection into the pericardium of 20 cc. of lipiodol following withdrawal of 100 cc. of the pericardial effusion, it became evident that the acute outline of the cardiohepatic angle was due to the extremely thickened parietal layer of the pericardium, and that there were no adhesions. Repeated lipiodol injections, at from five to fifteen days intervals, did not seem to influence the affection which ran the usual course. The absorption of the iodized oil in the pericardial cavity was very slow, as it was recovered on puncture twenty days later.

Iodized Oil in Diagnosis of Subphrenic Cysts.—Castex, Romano and Gonzalez injected lipiodol in a case of a suppurated hydatid and gas cyst, on the upper surface of the liver. Roentgenograms taken in different positions showed distinctly the contour of the cyst and its connections with the abdominal walls. The injections were also of great help in roentgenographic diagnosis of a suppurating pneumoperitonitis. The injections were always well tolerated.

Case of Hemogenia with Fatal Menorrhagia.—Frequent epistaxis and purpura before and after puberty became associated at the age of 15 with menorrhagia, prolonged for ten days every month. At 17 the patient presented a hemorrhagic effusion in the abdominal cavity, apparently of ovarian origin. Two grave menorrhagias, at a six weeks' interval, occurred at 18, causing death from anemia. The clinical features, the nonretractility of the blood clots, and the decreased number of platelets suggested the diagnosis of hemogenia. The bleeding time was not markedly changed. Payan thinks that diabetes in the father may have been responsible for the congenital debility of the liver and the disturbances of blood functioning in the daughter. There were also symptoms suggesting excessive ovarian and thyroid functioning. Extracts of different organs did not exert any action. Blood transfusions also failed to arrest the hemorrhagic tendency.

Recuperation of Sight in Implanted Eye of Triton.—Matthey's experiments were made on eighty-six tritons by Koppanyi's technic. He removed an eyeball in one of these lizard-like amphibians and implanted it in another. The aspect of the implanted eye was absolutely normal in ten months in four instances. Then he repeated the procedure with the second eye. One triton died after the second operation; in three the sight was apparently recovered in both eyes. The recovery of vision was manifested in tests with a blind triton for the control. No changes were noted in the optic nerve.

Sensitization from Skin Dressings.—Golovanoff applied dressings with horse serum or white of egg to the eroded skin of guinea-pigs, and left them for twenty-four hours. Fourteen days later the animals were given an intravenous test injection. This was followed by a specific anaphylactic shock. Sensitization can thus be induced by a superficial dressing as well as by the subcutaneous route.

Rôle of Bile in Colon Bacillus Infection.—Rabbits were given bile by the mouth, and then inoculated intravenously with a nonlethal dose of cultures of colon bacilli. While the control animals bore the injection without harm, all those sensitized with bile died in one or two days. Golovanoff emphasizes that it may be possible to vaccinate the intestinal wall against colon bacilli by ingestion of colon bacillus cultures.

Filtrable Tubercle Bacilli in Fluid of Artificial Pneumothorax.—Veber's observation confirmed that common tubercle bacilli may disappear from the effusion with an artificial pneumothorax, after a few months. The same effusion, after filtering, induced tuberculous lesions of glands in guinea-pigs, without the presence of a primary inoculation lesion. Evidently the fluid contained invisible, filtrable forms of tubercle bacilli.

Pulmonary Ventilation in School Children.—Billard and Gourdon's investigation of 150 school children disclosed a close relation between the vital capacity and the size of the chest. Consequently the vital capacity may be estimated if the size of the chest is known. They found the respiratory capacity of a child equal to one fifth of the size of the thorax; while it is equal to one third at the age of 20, and to one sixth and still less in advanced age; one thirtieth in those with emphysema.

Identity of Blood Groups and Interagglutination.—Du Bouchet reports two cases in which the maternal blood and that of the new-born belonged to the same group. While the infant's serum did not agglutinate the erythrocytes of the mother, there was pronounced agglutination of the infant's erythrocytes by the maternal blood serum. This agglutination disappeared in one instance by the eleventh day. Agglutination tests should be applied to the maternal blood, if it is used for transfusions in infants soon after birth.

Arthus' Phenomenon After Injection of Diphtheria Anatoxin.—Tzanck and his co-workers describe a case in which diphtheria anatoxin was used as a prophylactic measure in the father, mother and two children. All were injected with 0.5 cc. of anatoxin, taken from one ampule. The injection was followed, the next day, by an intense local and general reaction in the mother alone. The general phenomena persisted for five days, the local over five weeks. The local reaction resembled Arthus' phenomenon; but without suppuration or necrosis. The patient never had had diphtheria, and never had been injected with diphtheria antitoxin or any antiserum. There was no history of urticaria, asthma or other colloidoclastic manifestation. Intracardiac injections of 1 cc. of the patient's serum or of diphtheria anatoxin did not induce any reaction in guinea-pigs. Injection of 0.5 cc. of the woman's blood serum and 0.5 cc. of anatoxin induced phenomena of passive anaphylaxis in the animals. No anaphylaxis occurred with similar injections of serum from the father.

The Reticulo-Endothelial System and Anaphylaxis.—The *functioning* of the reticulo-endothelial cell system was experimentally blocked in guinea-pigs with injections of iron oxide, india ink or splenectomy. Beef serum was injected the next day and again the twentieth day. All died from anaphylaxis, the same as the control animals. Simitch concludes that the reticulo-endothelial tissue does not seem to take part in anaphylactic shock.

Vaccination of the New-Born Against Tuberculosis.—This report brings down to date the experiences of which a summary was given in these columns, March 6, 1926, p. 724.

New Horizon for Bone Surgery.—Leriche and Policard remark that as it seems to be definitely established now that mechanical conditions play an important part in shaping the growing bone, it seems theoretically possible to influence the healing and reconstruction of bone tissue after operations, modeling it, as it were. Their research has demonstrated that bone repair requires an optimal circulation; too much is as injurious in one way as too little in another, especially in the formation of the callus and healing of implants. They have noted that periarterial sympathectomy seemed to restore the normal balance in the circulation of the bone and surrounding tissue, accelerating ossification.

Protein Shock and the Vegetative Tonus.—Garrelon and Santenoise injected dogs and rabbits intravenously with peptone, under anesthesia. The drop of the arterial pressure was the criterion for the shock, while the oculocardiac reflex indicated the parasympathetic tonus. In animals with a normal oculocardiac reflex, the injection was followed by a gradual and moderate decline of the arterial pressure (by 2 or 3 cm.). The decrease of the pressure was prompt and considerable in dogs with pronounced vagotonia. In dogs with hypovagotonia, the fall of the arterial pressure was slight and briefly transient. Stimulation of the vagus by *simultaneous injections of pilocarpine* and peptone induced a violent shock. The shock was intense, sometimes even fatal, after combined injection of eserin and peptone. The same was observed with insulin, freed from albumin. On the contrary the shock was nil or very mild in animals treated previously with atropine. Research was also made on the influence of shock on the vegetative tonus. It appeared that injections of peptone induce an immediate rise of the tonus, succeeded soon by hypovagotonia, and then again vagotonia. The first injection of peptone may not induce shock in cases with hypovagotonia; but by its inversion of the vegetative tonus the second injection brings the shock. Clinical results were identical with the experimental. The by-effects of injections of pneumococcus or streptococcus antiserum were predominant in mental patients with exaggerated vagal tonus as, for instance, maniacs or epileptics. The injections were well tolerated in patients with low tonus, as in dementia praecox. *The data presented all testify to the close connection* between the parasympathetic tonus and the susceptibility to shock.

Blood After Radon Treatment of Cancer. A. Kotzareff.—p. 151.
Present Status of Vitamins. E. Fenner-Rhode.—p. 158.

Microscopy of the Sputum.—Liebmann regards microscopic examination of the sputum as a much neglected field. He prefers fixation of moist smears with methyl alcohol, and stains with a mixture of 15 parts of 1 per cent solution of thionin in methyl alcohol and 1 part of a similar solution of magdala red. An equal amount of water is added and the stain is left in contact with the smear for half an hour. The *neutrophil and eosinophil polymorphonuclears show* frequently a confluence of the nuclear segments, especially after addition of water, thus simulating myelocytes. A prevalence *of eosinophils is known in asthma. It announces the favorable* crisis in pneumonia, but has no prognostic significance in tuberculosis. The cells usually considered as alveolar epithelial cells are probably macrophages. They are normal constituents of the sputum, and are present also in the nose. The thick structure of their nucleus and the presence of nucleoli differentiate them from the monocytoid cells which appear only with affections of the alveoli, especially bronchopneumonia and pneumonia. They are evenly distributed over the field in these diseases. In pulmonary tuberculosis they occur in small heaps of four or ten or more elements. Cells with fatty granules are not a sign of tumor.

Latent Inflammation of Fissures of Lungs. C. Cantieri.—p. 378.

Changes in Alkaloids on Standing.—Mura and Petiti relate that of all the aqueous solutions of various alkaloids tested, quinine was the only one that seemed to be unmodified by the end of six months, responding the same as before to both chemical and biologic tests.

Leukopedesis into the Stomach in Various Morbid Conditions.—Mauro recalls that M. Ascoli and Moreschi called attention in 1901 to a proteolytic ferment in the leukocytes, but it is only recently that Loeper and Marchal have emphasized the importance of this as an element in gastric digestion. The leukocytes swarm into the stomach during digestion, and this endogastric leukopedesis is promoted by certain foods, and is inhibited by excessive acidity or gastritis, and certain other diseases. Mauro urges study of the import of these fluctuations for diagnosis and prognosis.

The Blood Pressure in Lead Poisoning.—Invernizzi has been investigating conditions as to the blood pressure in 369 cases of lead poisoning from 1910 to 1923. In acute lead poisoning and in acute exacerbations of chronic plumbism, *the blood pressure is very high, but the sudden drop as other* symptoms subside confirms the assumption of angiospasm as responsible for it. In other chronic forms of lead poisoning, *the pressure is low, as lead depresses the heart action.* After it has entailed arteriosclerosis, the systolic pressure is high, but the diastolic is low. This is explained by a reflex action from the influence of the lead on the splanchnic nerves and kidneys.

Prevention and Treatment of Cancer. R. Marchesini.—p. 120.

Febrile Tertiary Syphilis.—Bacheca treated a young woman with fever, a chlorotic blood picture, and a tumor in the epigastrium. She recovered after antisyphilitic treatment. He quotes Boerhave's motto: *In dubiis suspice luem!* This applies especially to fever of doubtful origin.

Hyperpyrexia from Syphilitic Meningitis.—The extremely high temperature (42.4 C.) in Monateri's patient was probably due to syphilitic meningitis.

Riforma Medica, Naples

42: 145-168 (Feb. 15) 1926

The Practice of Artificial Pneumothorax. A. Viton.—p. 1537. C'tn.
The Rôle of Silica in Growth of Plants. A. L. Herrera.—p. 1579.

Autohemotherapy in Asthma.—Carranza and Orgaz drew the patient's blood and reinjected 4 or 5 cc. subcutaneously in the arm or leg, gradually increasing to 8 or 10 cc. This attenuated or arrested the attack of asthma. The procedure is a kind of desensitization, and hence is applicable only to the anaphylaxis type of asthma. No effect was apparent in three of their thirteen cases; the failures were probably due to the secondary nature of the asthma. All the others were much improved or have been cured to date. From four to ten weekly injections were given; the ages ranged from 16 to 51.

Melanoma of the Intestine. E. Peritz.—p. 242.

Experimental Bronchial Asthma.—Braeucker made a morphologic and experimental study of the nerves of the lungs in dogs. The pneumogastric contains not only vasoconstrictor but also vasodilator fibers. There is besides this in dogs a spinal bronchomotor innervation running over the vagosympathetic (not over the cardiac nerves). The pulmonary plexus consists of as many sympathetic fibers as of pneumogastric fibers. Only the fibers of the posterior bronchial branches transmit motor impulses to the finest bronchioli.

Bacteriology of the Stomach.—Bitter and Löhr investigated the germs in the stomach and duodenum in various diseases, especially with ulcer of the stomach and duodenum and carcinoma of the stomach. With normal acid secretion, they found the usual harmless gram-positive microbes in the stomach and duodenum. With lowered acidity, the colon flora ascends more and more proximad, and it invades the stomach in achylia.

Roentgen-Ray Treatment of Tuberculosis.—Siedamgrotzky concludes from 730 cases of surgical tuberculosis treated with the roentgen rays that it is best suitable for tuberculous lymphomas, spina ventosa and fistulas. The results in tuberculosis of large joints were not encouraging.

Anatomy of Common Bile Duct.—Fuchs shows that there is danger of injury of the pancreas as soon as a transduodenal choledochotomy is made farther than through the muscular layer. It is possible, although difficult, to reach the common bile duct back of the duodenum. He concludes that the standard procedure at Hochenegg's clinic is rational: The manipulations in the juxtaduodenal part of the bile duct are made either from a supraduodenal opening, or the last part of the duct is avoided by supraduodenal choledochoduodenoanastomosis.

Viability of Transfused Erythrocytes.—Wildegans concludes that the transfused erythrocytes live for several weeks. It is possible to check up microscopically for two weeks on erythrocytes transfused from a polycythemia patient to an anemic subject. The iso-agglutination tests did not yield dependable results in identification of the transfused cells.

Nerves of Arteries.—Hirsch concludes that there is no histologic basis for explanation of the results of so-called periarterial sympathectomy.

Artificial Chyluria.—The chyluria in Lagemann's case (a police officer) was probably due to introduction of milk into the bladder by the subject.

*Internal Treatment of Peptic Ulcer. U. Steinberg.—p. 285.
*Spasms and Pains in Gastric Ulcer. R. Cobet and K. Gutzeit.—p. 295.
*Hydrochloric Acid in Pernicious Anemia. G. Taubmann.—p. 309.

Central Stimulants of Metabolism.—Schoen and Kaubisch report experiments on healthy persons. They found an increase of the basal metabolic rate amounting to from 15 to 20 per cent after injections of caffeine and of compounds of the camphor group. The increase was still stronger after lobelin. The respiratory quotient increased after lobelin and strychnine.

Aplastic Anemia.—Denecke's patient developed grave anemia of the aplastic type with microcytes and megalocytes, but without increased bilirubin in the serum. The spleen and lymph nodes became enlarged. The histologic findings were those of lymphatic pseudoleukemia.

Benzine Poisoning.—Schustrow and Salistowskaja made experiments on inhalation of petroleum ether by rabbits or guinea-pigs. They found emaciation, aplastic hemolytic anemia, increased fragility of red cells and a leukopenia affecting all the white cells. They explain the poisoning by the action of the substance on the lipoids. The serum in the poisoned animals contained less cholesterol than in the controls. They believe that with inhalation, more erythrocytes are affected than with internal administration.

Habituation to Benzine.—Schustrow and Salistowskaja studied the increasing resistance to poisoning with petroleum ether. The time of appearance of convulsions and of restitution furnished the basis for comparison. The animals in the first week had convulsions within thirteen to fifteen minutes after the beginning of the inhalation, and required fifteen minutes for recovery. At the end of the second week, they were able to stand three or four times more of the benzine. The convulsions began in seventy to ninety minutes and the animals recuperated in one or two minutes. After an injection of 0.1-0.2 Gm. of lecithin in olive oil these animals became immediately as susceptible as unaccustomed animals. They conclude that the resistance is due simply to the loss of fat in the poisoned animals and consequently a diminished absorption by the blood. The administration of fat seems to be contraindicated during chronic exposure to benzine, but would seem advantageous in treatment. They mention Nick's patient who recovered after intravenous injection of 5 cc. of a 10 per cent lecithin emulsion in spite of poisoning with 88 Gm. of benzene.

Internal Treatment of Peptic Ulcer.—Steinberg reports fine results of treatment of ulcers of the stomach and duodenum with silver nitrate. He administers three or four times daily 1 tablespoonful of a solution of 0.25 up to 0.4 Gm. of silver nitrate in 120 cc. of water before meals.

Spasms and Pains in Gastric Ulcer.—Cobet and Gutzeit failed in their attempts to cause pains in gastric ulcer patients by chemical (acid) or electrical stimuli. They conclude that hyperacidity alone cannot account for the pains and spasms in such patients.

Hydrochloric Acid in Pernicious Anemia.—Taubmann reports a case with almost every symptom of pernicious anemia, but with free hydrochloric acid in the stomach. In spite of this, the duodenum contains colon bacilli.

Laryngeal Diphtheria.—Bókay intubates even in infants, but controls them daily to detect injury from pressure. He had a mortality of 49 per cent among 102 children under the age of 2 treated by tracheotomy when the intubation had failed.

Serum Bilirubin in Secretory Disturbances of the Stomach.—Arnoldi and Schechter estimated the blood bilirubin content with Meulengracht's nonspecific method. It was near the lower limits of normal in hyperacidacity and near the upper limits in subacity and achylia. They believe that this is due to increased liver function with rapid transformation of indirect bilirubin into the direct form (van den Bergh) in hyperacidity, and lowered liver function in achylia.

Combination of Insulin and Dextrose.—Grunenberg had excellent results in diseases of the pancreas and liver (including jaundice), with daily injection of 10 units of insulin followed by 40 Gm. of dextrose (in injection, by the mouth, or by enema).

Bronchopneumonia in Infants.—Hamburger prefers the carrying around of children to their complete rest in bed. Cold air and sedatives as well as arteriotomy improve the prognosis in infants and small children.

Monocytic Angina.—Kwasniewski and Henning report eight cases of monocytic angina. The generalized affection of the lymphatic apparatus may occur without the tonsillitis, which suggests a common origin for both.

Metabolism of Erythrocytes in Anemia.—Denecke found an increase in acidity of the anemic blood in standing. He believes that it is not due to glycolysis, although the latter may take place. He thinks that it is connected with the production of carbon dioxide and diffusion of the chlorine ions into the erythrocytes.

Puncture and Transfusion Apparatus. E. Marr.—p. 294.

Blood Cholesterol and the Liver.—Thannhauser and Schaber observed a lowered cholesterol-ester: cholesterol ratio in the blood and serum from patients with parenchymatous disturbances of the liver. They believe that it is due to an injury of the liver ferment which normally splits the cholesterol esters (only free cholesterol is excreted by the bile). Similar observations, with a different explanation, had been made by Bürger before.

Carbohydrates Plus Insulin in Coma.—Bucka concludes that in cases of deep coma, insulin alone is indicated. This applies also to beginning coma being treated at a clinic with facilities for continuous control of the blood sugar. In the precoma stage, the dosage of insulin is difficult, and she recommends addition of sugar.

Oxaluria.—Piccininni and Lombardi confirm Sandro's observation on a colon bacillus strain which occurs in the feces of subjects with oxaluria, and produces in the first passage (and especially in symbiosis with *Bacillus subtilis*) oxalic acid. It caused oxaluria in healthy subjects when administered in capsules.

Hemoglobinuria in Arsphenamine-Bismuth Treatment.—Munter and Steinitz observed hemoglobinuria and later nephritis in a young syphilitic man treated with neo-arsphenamine and bismuth. General muscular spasms, resembling those of the Haff disease, were present. The patient died from uremia. The blood pressure remained only at the upper limits of the normal range.

Serology of Syphilis.—Klopstock and Hilpert demonstrate that the coincidence of positive results with several methods is much greater in subjects with a history of syphilis than in others.

Cancer and Its Treatment. O. Strauss.—p. 263. C'td.
Syphilis. F. Pinkus.—p. 266.

Gonorrhea in Men.—Balog pleads for better knowledge of Picker's research. The latter considers gonorrhea as a general disease affecting in men chiefly the glands of the urogenital tract (Littré's, seminal vesicles, prostate). His treatment consists in lavage and bimanual expression of the contents of the prostate and the seminal vesicles, the patient in the erect position and with his bladder filled.

Pancreas Function Test.—Papp publishes the details of Carpi's method of estimation of the trypsin content of the duodenal fluid or the feces. Gelatin is the medium used, and sodium fluoride serves to inhibit growth of germs. Blood inhibits the action of trypsin, pus stimulates it.

*The Menstrual Poison Question. G. Schubert and O. Steuding.—p. 201.
Injuries of Sex Organs. W. Raaflaub.—p. 206.
Pyelitis. E. Puppel.—p. 224.

Deflexion Presentations.—Kamniker recommends conservative treatment in all deflexion presentations. Among 147 cases of Peham's clinic, 98 per cent of the face presentations, 51.5 per cent of the sinciput and 46 per cent of the forehead presentations were delivered without any intervention, except sometimes rupture of the bag of waters and episiotomy.

Exploratory Puncture of Rectovaginal Pouch in Ectopic Pregnancy.—Zeitlin warns against basing the diagnosis exclusively on the result of the puncture. Yet it is useful if pus or micro-organisms are discovered, since a laparotomy is dangerous in such cases. The puncture is harmless, if made in the middle line of the posterior vaginal wall and if it is not attempted in a state of severe shock.

Resuscitation of the New-Born.—Wachenfeldt had perfect results with intracardiac injection of 0.5 and 1 cc. of epinephrine (1:1,000) in two apparently stillborn children.

Vaginal Bacteria and the Puerperium.—Broich finds that the degree of bacteriological purity is in no relation to the puerperal morbidity of pluriparas. In primiparas, a low degree of bacteriologic purity usually entails a mild infection characterized by the fetid odor of the lochia.

The Menstrual Poison Question.—Schubert and Steuding repeated Schick's experiments on the alleged menstrual poison, and added certain others. They found no indications of its presence.

Gland Fever. F. Mündel and J. Franz.—p. 545.
Thick Feedings in Pylorospasm. C. Stamm and O. Herz.—p. 553.

Reaction Time in Infants.—Peiper measured the time between an auditory stimulus and the motor reaction thereto in infants. It was about a quarter of a second in infants from 2 to 4 months of age. The average variation was 0.068 seconds. The reaction time of sleeping infants is longer—up to a few seconds.

Treatment of Tuberculous Meningitis—Klinke tried Sharp's method (intraspinal insufflation of oxygen) in six children with tuberculous meningitis All of them died

Vasomotors in Measles and Pirquet Test—Kollar observed a diminished skin reaction to mechanical stimuli (red dermography) in measles during the period of tuberculin anergy She concludes that this is another indication of the significance of the vasomotors *for the tuberculin skin test*

Bundle Block D Scherf—p 327
Polymyositis L Schill—p 353
*The Phthisic Habitus A V Frisch and K P Eiselsberg—p 361

Respiratory Metabolism—Pollitzer and Stolz found at night a *lowering of the specific dynamic action of ingested and* injected proteins They recommend therefore to administer injections of tuberculin in the evening (to avoid fever), and injections intended to provoke fever, in the morning It is possible that work or eating at night is an overlooked pathogenic factor

Pathogenesis of Angina Pectoris—Singer concludes from his experiments on dogs that ischemia of the heart muscle does not cause pains The epicardium pericardium, aorta and coronary arteries are sensitive *Ligation of the latter hurts* only if the adventitia is preserved

New Blood Constituent—*Leimdorfer* gives the details of his isolation and estimation of the compound he found in erythrocytes It is a basic substance, giving the diazo reaction, but it is not identical with the compound responsible for the diazo reaction in the urine Except for recent syphilis and certain cases of fever, it was most extraordinarily increased in tuberculosis

Hemolytic Jaundice—Boros confirms the small diameter and relatively normal volume of the erythrocytes in hemolytic jaundice This seeming microcytosis disappears after splenectomy, although the fragility remains high He believes that the change of shape is only a secondary symptom of regeneration, and that it occurs in anemias of other origin

Arthritis in Psoriasis—Morgenstern believes that psoriasis is a general affection of the body The arthropathies which occur with it would correspond to a secondary or tertiary stage The diagnosis is made by the parallelism between the manifestations on the skin and in the joints and by exclusion of arthritis of other origin

"Aseptic" Epidemic Meningitis—Wallgren describes a poradic form of acute meningitis The clinical symptoms re typical, the prognosis is good, the disease lasts only a few days The cerebrospinal fluid contains lymphocytes and is sterile

The Phthisic Habitus—*Frisch and Eiselsberg deny any* predisposing influence from "habitus phthisicus" It is rather a sequel of tuberculosis Even here it occurs usually with the mild forms, not with the destructive "phthisis"

Wiener klinische Wochenschrift, Vienna

Treatment of Neuralgia S Erben—p 191
Hormone Therapy in Gynecology and Obstetrics I Herrmann Supplement Pp 1 16

The Nose—Hofbauer reviews the experimental evidence on the passage of air through the nose Under normal conditions, only the upper part of the nose—not the broad base—is used for it This is due to the fact that the nostrils are horizontal, so that the air has to ascend vertically The *absence of the external nose (war wounds)* causes respiratory disturbances due to the direct impact of the current of air

Fourth Disease.—Hochsinger is convinced that the "fourth disease" (Filatow-Dukes) exists as a clinical entity He differentiates it from German measles by the *scarlatiniform* rash, and from scarlet fever especially by the absence of subsequent desquamation He suggests the name "scarlatinella

Treatment of Squint.—Meller emphasizes the fact that concomitant strabismus begins only intermittently at the age of 3 or 4, when the child begins fixation of small objects close to his eyes The physician discovers it when holding a piece of paper in front of one eye and asking the child to look with the other eye at an object close to the eye Conservative measures can succeed only if treatment starts immediately It consists in atropinization of the eyes, and exact correction *of the refraction anomaly* ' *If the squint is of longer standing*, the atropine treatment has to be kept up for a longer period Besides this, it is necessary to train the weaker eye, to avoid amblyopia This is accomplished with a small black disk fitting tightly to the orbit of the healthy eye This special monocular goggles should be worn for several hours daily As long as there is hope for success with conservative measures surgical intervention can be only injurious Even if the treatment fails, he advises against intervention before *the twelfth to the fourteenth year The squint may disappear* spontaneously, and it is preferable to defer surgery until the child is intelligent enough to submit to local anesthesia No dosage of the degree of intervention required is possible under general anesthesia

Dyspareunia in Pregnancy—Galant rejects dyspareunia as a cause of sterility Contrary to this he thinks that the frequency of dyspareunia in sterility is a sequel or a coordinated phenomenon He found regularly a lowering of the libido during pregnancy, and its disappearance after the sixth month This may be due chiefly to the absence of the uterine part of the orgasm, but it is also due to some extent to mental causes (anxiety not to injure the fetus)

Lutein Cells and Chorio-Epithelioma.—Herold's patient had a malignant chorio-epithelioma It retrogressed after ovariectomy, which revealed a strong proliferation of lutein cells

Placenta Praevia—Wagner reviews the 172 cases of placenta praevia observed in Benckiser's clinic from 1893 to 1923 among 19,027 childbirths The results have improved since transperitoneal cesarean section became the method of choice

Cytolytic Action of Selenium. A. H. Roffo and L. M. Correa.—p. 82.

Food and Growth of Cancer.—Ludwig fed sixty mice with a diet free from vitamins for twelve days before and after inoculation of carcinoma. The cancer did not take in any of them. The vitamin-free food had no effect when given after the appearance of cancer. The results were similar, although not so perfect (35.7 per cent protection), in fourteen rats inoculated with a sarcoma after fifty to sixty days of a diet free from vitamins.

Tissue Cultures and Oxygen.—Fischer and Andersen found that a higher oxygen pressure killed cultures of Rous' chicken sarcoma faster than cultures of fibroblasts. With suitable doses, pure cultures of fibroblasts were obtained from cultures mixed with sarcoma. They discuss the therapeutic possibilities.

Cancer Growth and the Endocrines.—The inoculated tumors seemed to be inhibited in their growth, in Elsner's experiments, by injections of a testis extract and—to a less extent—by a pituitary extract. A pituitary extract from another manufacturer seemed to enhance the growth. He is pessimistic as to the outlook for organotherapy in cancer.

Psychotherapy in Tuberculosis. J. Kollarits.—p. 324.

Tuberculosis in Tobacco Workers.—Müller and Berghaus were delegated to study the cause of the high tuberculosis mortality in a rural district near Mannheim. It seemed at first that work in tobacco factories is to be incriminated. Yet they found that these workers are weak before they start working there, the strong ones preferring better paid occupations. The infection in the plant is certainly possible, but it seemed that infection in the home was a more important factor. The hygienic conditions in the homes of most of the patients were horrible.

Sanocrysin in Experimental Tuberculosis.—Bang tested the action of Sanocrysin in vitro and in vivo. Five bovine and three human strains of tubercle bacilli grew in a concentration of 1:5,000 Sanocrysin, although Møllgaard claims that it inhibits their growth in a concentration of 1:100,000. Møllgaard's cultures used for infection of animals were of an abnormally low virulence. When using fresh cultures or pus from spontaneous tuberculosis of cattle, Bang never obtained any curative action from Sanocrysin.

The Mâtêfy Test.—Rosenhagen found that the Mátéfy test has no practical value in pulmonary tuberculosis.

Fat Embolism After Bone Surgery.—Schwamm explains the fat embolism after orthopedic interventions on children—as previously reported here—by pointing out that all these patients had been operated on before, and had been kept in plaster casts for a long period. He emphasizes that Lorenz' clinic tries to avoid redressment operations on such children for several months after the removal of the cast. The same applies to children after poliomyelitis, who had not been walking. The fatty degeneration of the bone marrow predisposes them to fat embolism. Dieting, light, cautious (!) massage and passive movements should always precede surgery on such children.

Cesarean Section in Eclampsia. S. Liebmann.—p. 414.

Rupture in Scar from Cesarean Section.—Steinberg concludes from his case that a *second cesarean section should* be done at the latest at the beginning of labor pains.

Gonorrhea of Eye After Cesarean Section.—Neumann delivered the infant by a cesarean section. In spite of this a gonococcal conjunctivitis developed on the second day. He attributes it to the early bursting of the bag of waters.

Cesarean Section in Eczema.—Liepmann regards eczema of the vulva, containing streptococci, as an indication for abdominal cesarean section. In his case a placenta praevia furnished an additional indication.

Cesarean Section After Death.—Noltmann made a cesarean section six minutes after death of the mother from pulmonary embolism. The child was asphyxiated, but survived. He made another cesarean section on a woman with mitral stenosis and beginning pulmonary edema, under lumbar anesthesia, and in the sitting position. The child was living and the mother improved rapidly.

Plague Bacilli Do Not Survive in the Fur of Siberian Marmots. N. Gaisky.—p. 15.
Stain for Blood and Blood Parasites. K. Plavtoff.—p. 119.

The Dick Test in Scarlet Fever.—Izabolinsky and Lipkin made their research with toxin obtained from seven strains of streptococci found in the throat of scarlet fever patients. They used also three strains from cultures of pus from postscarlatinal otitis, and a culture of streptococci from empyema. The streptococci were isolated from patients with prolonged forms of scarlet fever as well as from those with the fulminating form. Among the different species, there was also the diplococcus streptococcus, the frequent presence of which in scarlet fever was emphasized by Gabritchevsky. Certain streptococci were hemolytic; others were not. Dextrose agar and Martin's bouillon were used for the cultures; the latter were kept in the thermostat for six days and then passed through a Chamberland filter. It was established that intradermal injection of 0.1 cc. of the toxin, diluted 1:2,000, *is able to induce redness and infiltration at the point of* injection. Of 430 reactions only 390 could be observed within twenty-four hours. Redness started after six hours; reached the maximum after twenty-four hours, and disappeared in from thirty-six to forty-eight hours. In order to avert pseudoreactions, a simultaneous injection was made on the other arm with this toxin heated to 95 C. for an hour. From 70 to 76.2 per cent of positive tests were noted below the age of 15; 53.1 per cent between 15 and 25, and 33.3 per cent after 25. The reaction was positive in 22.5 per cent of forty subjects with a scarlet fever history. The results were identical with the toxin heated to 55 C. for thirty minutes. It is possible that while the toxic form of scarlet fever entails immunity, there is no immunity with the localized form (predominant lesions in the nose and throat) or the exanthematous. This may possibly explain the positive Dick tests after scarlet fever.

Treatment of Tuberculous Meningitis.—Klinke tried Sharp's method (intraspinal insufflation of oxygen) in six children with tuberculous meningitis. All of them died.

Vasomotors in Measles and Pirquet Test.—Kollár observed a diminished skin reaction to mechanical stimuli (red dermography) in measles during the period of tuberculin anergy. She concludes that this is another indication of the significance of the vasomotors for the tuberculin skin test.

Polymyositis. E. Schill.—p. 353.
*The Phthisic Habitus. A. V. Frisch and K. P. Eiselsberg.—p. 361.

Respiratory Metabolism.—Pollitzer and Stolz found at night a lowering of the specific dynamic action of ingested and injected proteins. They recommend therefore to administer injections of tuberculin in the evening (to avoid fever), and injections intended to provoke fever, in the morning. It is possible that work or eating at night is an overlooked pathogenic factor.

Pathogenesis of Angina Pectoris.—Singer concludes from his experiments on dogs that ischemia of the heart muscle does not cause pains. The epicardium, pericardium, aorta and coronary arteries are sensitive. Ligation of the latter hurts only if the adventitia is preserved.

New Blood Constituent.—Leimdörfer gives the details of his isolation and estimation of the compound he found in erythrocytes. It is a basic substance, giving the diazo reaction, but it is not identical with the compound responsible for the diazo reaction in the urine. Except for recent syphilis and certain cases of fever, it was most extraordinarily increased in tuberculosis.

Hemolytic Jaundice.—Boros confirms the small diameter and relatively normal volume of the erythrocytes in hemolytic jaundice. This seeming microcytosis disappears after splenectomy, although the fragility remains high. He believes that the change of shape is only a secondary symptom of regeneration, and that it occurs in anemias of other origin.

Arthritis in Psoriasis.—Morgenstern believes that psoriasis is a general affection of the body. The arthropathies which occur with it would correspond to a secondary or tertiary stage. The diagnosis is made by the parallelism between the manifestations on the skin and in the joints, and by exclusion of arthritis of other origin.

"Aseptic" Epidemic Meningitis.—Wallgren describes a sporadic form of acute meningitis. The clinical symptoms are typical; the prognosis is good; the disease lasts only a few days. The cerebrospinal fluid contains lymphocytes and is sterile.

The Phthisic Habitus.—Frisch and Eiselsberg deny any predisposing influence from "habitus phthisicus." It is rather a sequel of tuberculosis. Even here it occurs usually with the mild forms, not with the destructive "phthisis."

*Treatment of Squint. J. Meller.—p. 190.
Treatment of Neuralgia. S. Erben.—p. 191.
Hormone Therapy in Gynecology and Obstetrics. E. Herrmann. Supplement. Pp. 1-16.

The Nose.—Hofbauer reviews the experimental evidence on the passage of air through the nose. Under normal conditions, only the upper part of the nose—not the broad base—is used for it. This is due to the fact that the nostrils are horizontal, so that the air has to ascend vertically. The absence of the external nose (war wounds) causes respiratory disturbances due to the direct impact of the current of air.

Fourth Disease.—Hochsinger is convinced that the "fourth disease" (Filatow-Dukes) exists as a clinical entity. He differentiates it from German measles by the scarlatiniform rash, and from scarlet fever especially by the absence of subsequent desquamation. He suggests the name "scarlatinella."

Treatment of Squint.—Meller emphasizes the fact that concomitant strabismus begins only intermittently at the age of 3 or 4, when the child begins fixation of small objects close to his eyes. The physician discovers it when holding a piece of paper in front of one eye and asking the child to look with the other eye at an object close to the eye. Conservative measures can succeed only if treatment starts immediately. It consists in atropinization of the eyes, and exact correction of the refraction anomaly. If the squint is of longer standing, the atropine treatment has to be kept up for a longer period. Besides this, it is necessary to train the weaker eye, to avoid amblyopia. This is accomplished with a small black disk fitting tightly to the orbit of the healthy eye. This special monocular goggles should be worn for several hours daily. As long as there is hope for success with conservative measures, surgical intervention can be only injurious. Even if the treatment fails, he advises against intervention before the twelfth to the fourteenth year. The squint may disappear spontaneously, and it is preferable to defer surgery until the child is intelligent enough to submit to local anesthesia. No dosage of the degree of intervention required is possible under general anesthesia.

Abdominal Pregnancy. L. Schoenholz.—p. 652.
The Dilatation Period. B. Aschner.—p. 710.

Dyspareunia in Pregnancy.—Galant rejects dyspareunia as a cause of sterility. Contrary to this, he thinks that the frequency of dyspareunia in sterility is a sequel or a coordinated phenomenon. He found regularly a lowering of the libido during pregnancy, and its disappearance after the sixth month. This may be due chiefly to the absence of the uterine part of the orgasm, but it is also due to some extent to mental causes (anxiety not to injure the fetus).

Lutein Cells and Chorio-Epithelioma.—Herold's patient had a malignant chorio-epithelioma. It retrogressed after ovariectomy, which revealed a strong proliferation of lutein cells.

Placenta Praevia.—Wagner reviews the 172 cases of placenta praevia observed in Benckiser's clinic from 1893 to 1923 among 19,027 childbirths. The results have improved since transperitoneal cesarean section became the method of choice.

Multiple Carcinomas. H. Siebke.—p. 66.
Cytolytic Action of Selenium. A. H. Roffo and L. M. Correa.—p. 82.

Food and Growth of Cancer.—Ludwig fed sixty mice with a diet free from vitamins for twelve days before and after inoculation of carcinoma. The cancer did not take in any of them. The vitamin-free food had no effect when given after the appearance of cancer. The results were similar, although not so perfect (35.7 per cent protection), in fourteen rats inoculated with a sarcoma after fifty to sixty days of a diet free from vitamins.

Tissue Cultures and Oxygen.—Fischer and Andersen found that a higher oxygen pressure killed cultures of Rous' chicken sarcoma faster than cultures of fibroblasts. With suitable doses, pure cultures of fibroblasts were obtained from cultures mixed with sarcoma. They discuss the therapeutic possibilities.

Cancer Growth and the Endocrines.—The *inoculated tumors* seemed to be inhibited in their growth, in Elsner's experiments, by injections of a testis extract and—to a less extent—by a pituitary extract. A pituitary extract from another manufacturer seemed to enhance the growth. He is pessimistic as to the outlook for organotherapy in cancer.

Antiformin Enrichment Method. W. Mueller.—p. 318.
*The Matefy Test. H. Rosenhagen.—p. 321.
Psychotherapy in Tuberculosis. J. Kollarits.—p. 324.

Tuberculosis in Tobacco Workers.—Muller and Berghaus were delegated to study the cause of the high tuberculosis mortality in a rural district near Mannheim. It seemed at first that *work in tobacco factories is to be incriminated.* Yet they found that these workers are weak before they start working there, the strong ones preferring better paid occupations. The infection in the plant is certainly possible, but it seemed that infection in the home was a more important factor. The hygienic conditions in the homes of most of the patients were horrible.

Sanocrysin in Experimental Tuberculosis.—Bang tested the action of Sanocrysin in vitro and in vivo. Five bovine and three human strains of tubercle bacilli grew in a concentration of 1:5,000 Sanocrysin, although Møllgaard claims that it inhibits their growth in a concentration of 1:100,000. Møllgaard's cultures used for infection of animals were of an abnormally low virulence. When using fresh cultures or pus from spontaneous tuberculosis of cattle, Bang never obtained any curative action from Sanocrysin.

The Mătĕfy Test.—Rosenhagen found that the Mátefy test has no practical value in pulmonary tuberculosis.

Fat Embolism After Bone Surgery.—Schwamm explains the fat embolism after orthopedic interventions on children—as previously reported here—by pointing out that all these patients had been operated on before, and had been kept in plaster casts for a long period. He emphasizes that Lorenz' clinic tries to avoid redressment operations on such children for several months after the removal of the cast. The same applies to children after poliomyelitis, who had not been walking. The fatty degeneration of the bone marrow predisposes them to fat embolism. Dieting, light, cautious (?) massage and passive movements should always precede surgery on such children.

Delivery After Death. H. Hellendall.—p. 412.
Cesarean Section in Eclampsia. S. Liebmann.—p. 414.

Rupture in Scar from Cesarean Section.—Steinberg concludes from his case that a second cesarean section should be done at the latest at the beginning of labor pains.

Gonorrhea of Eye After Cesarean Section.—Neumann delivered the infant by a cesarean section. In spite of this a gonococcal conjunctivitis developed on the second day. He attributes it to the early bursting of the bag of waters.

Cesarean Section in Eczema.—Liepmann regards eczema of the vulva, containing streptococci, as an indication for abdominal cesarean section. In his case a placenta praevia furnished an additional indication.

Cesarean Section After Death.—Noltmann made a cesarean section six minutes after death of the mother from pulmonary embolism. The child was asphyxiated, but survived. He made another cesarean section on a woman with mitral stenosis and beginning pulmonary edema, under lumbar anesthesia, and in the sitting position. The child was living and the mother improved rapidly.

*The Dick Test in Scarlet Fever. M. Izabolinsky and J. Lipkin.—p. 3.
Plague Bacilli Do Not Survive in the Fur of Siberian Marmots. N. Gaisky.—p. 15.
Stain for Blood and Blood Parasites. K. Plavtoff.—p. 119.

The Dick Test in Scarlet Fever.—Izabolinsky and Lipkin made their research with toxin obtained from seven strains of streptococci found in the throat of scarlet fever patients. They used also three strains from cultures of pus from postscarlatinal otitis, and a culture of streptococci from empyema. The streptococci were isolated from patients with prolonged forms of scarlet fever as well as from those with the fulminating form. Among the different species, there was also the diplococcus streptococcus, the frequent presence of which in scarlet fever was emphasized by Gabritchevsky. Certain streptococci were hemolytic, *others were not.* Dextrose agar and Martin's bouillon were used for the cultures; the latter were kept in the thermostat for six days and then passed through a Chamberland filter. It was established that intradermal injection of 0.1 cc. of the toxin, diluted 1:2,000, is able to induce redness and infiltration at the point of injection. *Of 430 reactions only 390 could be observed* within twenty-four hours. Redness started after six hours, reached the maximum after twenty-four hours, and disappeared in from thirty-six to forty-eight hours. In order to avert pseudo reactions, a simultaneous injection was made on the other arm with this toxin heated to 95 C. for an hour. From 70 to 76.2 per cent of positive tests were noted below the age of 15; 53.1 per cent between 15 and 25, and 33.3 per cent after 25. The reaction was positive in 22.5 per cent of forty subjects with a scarlet fever history. The results were identical with the toxin heated to 55 C. for thirty minutes. It is possible that while the toxic form of scarlet fever entails immunity, there is no immunity with the localized form (predominant lesions in the nose and throat) or the exanthematous. This may possibly explain the positive Dick tests after scarlet fever.

Treatment of Tuberculous Meningitis.—Klinke tried Sharp's method (intraspinal insufflation of oxygen) in six children with tuberculous meningitis. All of them died.

Vasomotors in Measles and Pirquet Test.—Kollár observed a diminished skin reaction to mechanical stimuli (red dermography) in measles during the period of tuberculin anergy. She concludes that this is another indication of the significance of the vasomotors for the tuberculin skin test.

Drainage of Clean Wounds. S. Ligin.—p. 398.
The Surgery of the Golden Age in Spain. F. Lejeune.—p. 400.

Fat Embolism After Bone Surgery.—Schwamm explains the fat embolism after orthopedic interventions on children—as previously reported here—by pointing out that all these patients had been operated on before, and had been kept in plaster casts for a long period. He emphasizes that Lorenz' clinic tries to avoid redressment operations on such children for several months after the removal of the cast. The same applies to children after poliomyelitis, who had not been walking. The fatty degeneration of the bone marrow predisposes them to fat embolism. Dieting, light, cautious (!) massage and passive movements should always precede surgery on such children.

*Cesarean Section After Death. E. Noltmann.—p. 408.
Delivery After Death. H. Hellendall.—p. 412.
Cesarean Section in Eclampsia. S. Liebmann.—p. 414.

Rupture in Scar from Cesarean Section.—Steinberg concludes from his case that a second cesarean section should be done at the latest at the beginning of labor pains.

***Gonorrhea of Eye After Cesarean Section.**—Neumann* delivered the infant by a cesarean section. In spite of this a gonococcal conjunctivitis developed on the second day. He attributes it to the early bursting of the bag of waters.

Cesarean Section in Eczema.—Liepmann regards eczema of the vulva, containing streptococci, as an indication for abdominal cesarean section. In his case a placenta praevia furnished an additional indication.

Cesarean Section After Death.—Noltmann made a cesarean section six minutes after death of the mother from pulmonary embolism. The child was asphyxiated, but survived. He made another cesarean section on a woman with mitral stenosis and beginning pulmonary edema, under lumbar anesthesia, and in the sitting position. The child was living and the mother improved rapidly.

**The Dick Test *in* Scarlet Fever.* M. Izabolinsky and J. Lipkin.—p. 3.
Plague Bacilli Do Not Survive in the Fur of Siberian Marmots. N. Gaisky.—p. 15.
Stain for Blood and Blood Parasites. K. Plavtoff.—p. 119.

***The Dick Test in Scarlet Fever.**—Izabolinsky and Lipkin* made their research with toxin obtained from seven strains of streptococci found in the throat of scarlet fever patients. They used also three strains from cultures of pus from postscarlatinal otitis, and a culture of streptococci from empyema. The streptococci were isolated from patients with prolonged forms of scarlet fever as well as from those with *the fulminating form. Among the different species, there* was also the diplococcus streptococcus, the frequent presence of which in scarlet fever was emphasized by Gabritchevsky. Certain streptococci were hemolytic; others were not. Dextrose agar and Martin's bouillon were used for the cultures; the latter were kept in the thermostat for six days and then passed through a Chamberland filter. It was established that intradermal injection of 0.1 cc. of the toxin, diluted 1:2,000, is able to induce redness and infiltration at the point of injection. Of 430 reactions only 390 could be observed within twenty-four hours. Redness started after six hours; reached the maximum after twenty-four hours, and disappeared in from thirty-six to forty-eight hours. In order to avert pseudoreactions, a simultaneous injection was made on the other arm with this toxin heated to 95 C. for an hour. From 70 to 76.2 per cent of positive tests were noted below the age of 15; 53.1 per cent between 15 and 25, and 33.3 per cent after 25. The reaction was positive in 22.5 per cent of forty subjects with a scarlet fever history. The results were identical with the toxin heated to 55 C. for thirty minutes. It is possible that while the toxic form of scarlet fever entails immunity, there is no immunity with the localized form (predominant lesions in the nose and throat) or the exanthematous. This may possibly explain the positive Dick tests after scarlet fever.

*The Roentgen Findings with Duodenal Ulcer. G. Jansson.—p. 10.
*Mechanism of Invagination of the Intestine. J. Heinonen.—p. 23.
*Syphilitic Temporomaxillary Arthritis. Baltscheffsky.—p. 38.
*Production of Carbon During Fasting. E. Adlercreutz.—p. 43.
Lambliasis with Pernicious Anemia. M. Savolin.—p. 53.
Insulin Made in Finland. T. W. Tallqvist.—p. 60.

The Roentgen-Ray Findings with Duodenal Ulcer.—Jansson drew the correct diagnostic conclusions from the niche, the filling defect, the retraction or the diverticulum in 70 per cent of his twenty-six operative cases; in half of the others his presumptive diagnosis was confirmed later. In the others the ulcer was in the pylorus region. Nine roentgenograms are reproduced.

Invagination of the Intestine.—Heinonen concludes that even a minute submucous tumor may induce stenosis, with or without spasm, and the bowel below this point atrophies and stretches. The bowel above slides into this gaping segment.

Syphilitic Arthritis of the Temporomaxillary Articulation.—The man had acquired syphilis seventeen years before the pains and swelling developed in the lower jaw, in five months gradually involving the temporal region, with severe pains in cheek and temples and trismus. A complete cure of the arthritis was realized in less than three weeks under iodide and neo-arsphenamine.

The Metabolism During Fasting.—Adlercreutz confirms the remarkable drop in the total metabolism even on the first day or so of fasting. It is especially noticeable in the production of carbon.

Hospitalstidende, Copenhagen

69: 1-28 (Jan. 6) 1926

*Kidney Function Tests. E. Busch.—p. 1.

Comparison of Kidney Function Tests.—Busch gives charts from twenty-five patients who had all had acute nephritis at some time and who recently had had seven different kinds of tests applied parallel. The findings in regard to Addis' "ratio," the diuresis during the three "ratio" hours, the urea content of the blood, and phenolsulphonphthalein elimination all fluctuated parallel to each other to a certain extent, while the responses to the thiosulphate test, Strauss' water test and the uric acid in the blood were more erratic. The phenolsulphonphthalein test is not very sensitive; normal findings were obtained in over 50 per cent of the cases. The Addis ratio test is the most sensitive of all, but it takes more time than the others. The amount of water eliminated in the three "ratio" hours seems to be a more reliable index of the water eliminating power of the kidney than the Strauss diuresis test. This enhances the value of the Addis ratio test as it throws light on the capacity of the kidneys for excretion of both urea and water. It can be supplemented further by a succeeding "thirst" test and microscopic examination of the urine. We thus ascertain the maximum excreting power for urea and for water, the maximum diluting and concentrating power, and the microscopic findings in the urine after twenty-four hours of dry nourishment.

69: 49-76 (Jan. 21) 1926

*Wassermann Reaction at Childbirth. H. Boas and Gammeltoft.—p. 49.
*Idem. Idem and K. Sick.—p. 61.
*Cancer of the Uterus. T. Dalsgaard-Nielsen.—p. 64.

The Wassermann Reaction in the Retroplacental Blood.—Boas and Gammeltoft analyze the literature on this subject and relate their own experience in comparing the response to the Wassermann test in the venous and the retroplacental blood in 273 patients. The retroplacental blood gave nonspecific responses to the Wassermann test and to various precipitation tests in forty-three of their 254 cases. It is thus not dependable for serologic tests.

The Wassermann Test in Parturients.—Boas, Gammeltoft and Sick obtained a positive reaction to the Wassermann test in the blood serum in 6.7 per cent of 2,200 parturients. The test was repeated a year or two later with practically similar findings, confirming that the positive responses had not been due to the pregnancy or childbirth. The reaction is as dependable during these conditions as at other times.

Cancer of the Uterus.—Fully 12 per cent of Dalsgaard-Nielsen's seventy-three patients with inoperable cancer of the cervix were relieved by radiotherapy from all their symptoms for periods up to three and a quarter years, and 52 per cent were improved for up to two and a half years; only 37 per cent showed no benefit. He advises radiotherapy even with operable cancer of the cervix, declaring that the results are as good as after operative treatment while the mortality is less; 16 per cent of ninety-four cases in this category were free from symptoms for periods up to three and a quarter years, and 55 per cent were materially improved for even longer than this. On the other hand, the results of operative treatment are particularly good with cancer of the body of the uterus, so that radiotherapy is not advised unless the general condition forbids operative intervention.

69: 77-96 (Jan. 28) 1926

Congenital Atresia of Biliary Passages. S. Hansen.—p. 77.
*Action of Cod Liver Oil Water. E. Rekling.—p. 91.

Cod Liver Oil-Water and Rickets.—Rekling reports that rats fed with the McCollum 3,143 ration developed rickets the same, whether or not they had been treated with Malmstrøm's cod liver oil-water. Malstrøm claims unusual efficacy for distilled water after prolonged contact with cod liver oil that had been exposed to ultraviolet rays. He assumes that the water takes up certain useful elements from the oil, but Rekling saw no evidence of rickets-preventing action by oral administration.

69: 97-120 (Feb. 4) 1926

*Chondromas in Joint Capsule. M. Fenger.—p. 97.
Extra Phalanx on Thumbs. A. Kristjansen.—p. 109.

Chondroma in the Capsule.—Fenger adds four new cases to the forty-four he has found on record in which chondromas had formed in an apparently sound knee, elbow or other joint. The development is extremely slow and benign, the growths do not encroach on the articulating surfaces and the functional disturbance is slight, as a rule. He regards the lesion as a benign tumor, of embryonal origin; there was no history of trauma in the majority of the cases. The roentgenogram shows hyaline lumps of cartilage, each with more or less of a pedicle, all on the inside of the capsule, and of various sizes. The lumps may break loose from the pedicle, and there may be thus a large number of loose bodies in the joint; 108 were removed from one elbow in one case.

Norsk Magazin for Lægevidenskaben, Oslo

87: 89-168 (Feb.) 1926

*Periarterial Sympathectomy. J. Holst.—p. 89.
*Pains in the Stomach in Children. Toverud.—p. 111.
*Treatment of Tuberculous Glands. P. Amundsen.—p. 119.
*Fungus Casts in the Urine. E. Gundersen.—p. 124.

Periarterial Sympathectomy.—Holst thinks that our knowledge of the vegetative nervous system is still so imperfect that the theories on which periarterial sympathectomy is based should be regarded with considerable reserve. In his own experience, the operation cured a case of leg ulcer, one of angiospasm and one of a neurotrophic ulcer, but in two cases of trophic ulcers complicated with arteriosclerosis, no benefit was derived.

Chronically Recurring Pain in the Stomach Region in Children.—Toverud refers to what has been called umbilical colic, chronic gastric catarrh and recurring colitis. The clinical picture suggests some general affection with the frequently recurring pains in the stomach region. He ascribes it to improper food, and lack of regular habits. The whole can be improved or cured by altering the mode of life, giving fruit in abundance, with green vegetables, sour milk and coarse, hard bread.

Roentgen-Ray Treatment of Tuberculous Glands.—Amundsen states that 81 per cent were cured of thirty-two patients with simple enlargement of the glands; 49 per cent of thirty-two with periadenitis in addition, and 77.4 per cent were cured of the fifty-three with suppuration and fistulas in the glands. The total cured thus averaged 66 per cent, and recurrence was observed in 4 per cent. All have been reexamined from two to nine years since the treatment.

Fungus Casts in Urine.—No albumin, pus or blood elements were found to explain the dysuria in the adult man, but actual casts were found which were evidently formed by a fungus of the penicillium species.

THE PHYSICIAN AND THE PATIENT OF THE FUTURE *

WENDELL C. PHILLIPS, M.D.
NEW YORK

Who can visualize or define the physician and the patient of the future? Human progress has always been associated with epoch making discoveries, and medicine, with other sciences, has blazed an enviable trail along the pathway of the ages. The marvelous achievements of the men of medicine of today are largely the outgrowth and fruition of similar achievements of the founders of our art. The history of no other science contains brighter pages than those illumined by the scientific conquests of the great men of medicine. The new developments in medical science have created the necessity for changes in modes, methods and economies so far reaching as to affect all phases of national, family and individual life. The physician both of the present and of the future must be an integral part of our civilization and much concerned with its changes.

THE HERITAGE OF THE FUTURE PHYSICIAN

Human sympathy evolved a desire in men to relieve sickness and sorrow. Sixty centuries have elapsed since Egyptian medicine first made its imprint on humanity. The Greeks gave us a new conception of medicine as an art. True, the early leaders in medicine were not only physicians but also priests and philosophers with little knowledge of anatomy, physiology or chemistry; but they implanted into the basic structures of our science the spirit of the healer.

Born four hundred years before Christ, surrounded by all that Greek culture and education meant in that day, Hippocrates was justly acclaimed the ideal physician, the great teacher and the founder of modern medicine. He not only taught his pupils what he knew of medicine, but he ever insisted that they should enter into professional life with high ethical ideals, which time has never effaced. To him we owe the formulation of the renowned hippocratic oath. By that vow the physician pledged himself to his teachers, and to disseminate to those who followed him the knowledge that he acquired. He pledged himself to follow that system of treatment which, according to his ability and judgment, would be for the benefit of his patients, and to abstain from whatever is deleterious and mischievous. He foreswore all harmful methods and resolved himself to practice for the benefit of the sick. "Whatever, in connection with my professional practice, or not in connection with it, I see or hear, in the life of men, which ought not to be spoken of abroad," he said, "I will not divulge, as reckoning that all such should be kept secret."

In those earlier periods, nothing was known of pathology and there was no scientific basis on which might be based a reasonable understanding of the causes of disease; nor had the physician or the patient the benefits to be derived from hospital or laboratory. But as time went on diphtheria, plague, tuberculosis, gynecologic diseases, obstetrics and affections of the eye, ear, nose and throat and many other diseases were fairly well defined.

The thirteenth century marked the foundation and rise of the universities and the gradual development of methodical medical studies. Dissection became more common; hence, the knowledge of anatomy and surgery progressed. Conscientious surgeons undertook serious operations without fear of criticism.

At this period few of the world's inhabitants reached adult life without an attack of smallpox. About 1796, Edward Jenner, practitioner of Gloucestershire, in England, boldly transferred cowpox infection from the hand of a young milkmaid into the arm of a young lad named Phipps, and immediately established the fact that immunity could be produced. As the result of vaccination, smallpox, the dread blemisher of human beauty and destroyer of human life, has become a thing of the past, except with people who foolishly neglect to avail themselves of the protection thus provided. But for Jenner's discovery, the faces of at least 50 per cent of this audience would be marred by pockmarks. The decimation of cities and communities from smallpox had continued throughout the centuries. But for this discovery, the continued high death rate from smallpox in foreign countries would have made it impossible for the United States in 1926 to have anything like a population of one hundred and ten million. In the light of this great discovery and boon to humanity, the proofs of which are positive and unassailable, is it not strange that prejudiced, benighted individuals and believers in cults like the antivivisectionists, the antivaccinationists, the chiropractors and the Christian scientists should presume to question the effectiveness of vaccination and unhumanly attempt by precept, by example and by propaganda to prevent its employment? Unfortunately, during the last few years in various parts of our country these forces for evil have succeeded in creating prejudice. Neglect of protective vaccination against smallpox has resulted in more or less alarming outbreaks of the disease. The state of Florida has just furnished an example of this kind. Wherever states have been lax regarding vaccination of school children, smallpox has spread, and yet this disease is an example of contagious disease which we *know* can be prevented.

---

* President's address before the American Medical Association at the Seventy-Seventh Annual Session, Dallas, Texas, April, 1926.

Louis Pasteur, father of the conception that bacteria (germs) are the direct cause of many diseases, gave to the world the key to the causes of putrid and suppurative diseases. Then came a positive demonstration of a specific germ—Robert Koch's discovery of the bacillus of tuberculosis.

Surgery adopted the principles first of antisepsis and later of asepsis. Few surgeons had ventured previously to perform major operations on the vital portions of the body, on account of the frightful mortality which resulted from suppuration. Joseph Lister, in 1878, showed how bacterial infection of wounds may be prevented by applying the principles of antisepsis in surgical operations. This momentous discovery revolutionized surgery and greatly lowered the mortality from surgical operations. Today surgeons, applying aseptic principles, do not hesitate to operate on any portion of the body, even the human heart.

In the fifty years since the discoveries that have just been mentioned, chemistry in medicine has made rapid strides, particularly in its relations to studies in physiology and metabolism. Chemical estimation of blood urea, proteins and gastro-intestinal contents and laboratory studies in cardiorenal and blood efficiency enable the physician to estimate the conditions of important organs of the body.

Meanwhile, physics, pathology, bacteriology, sanitation and preventive medicine have been developed to a high degree. The discovery of antitoxin for diphtheria has proved a boon to the child. The various animal carriers of disease have been determined and classified.

The work of Gorgas in making possible the building of the Panama Canal by the application of our knowledge of insect transmission of yellow fever and malaria, and the employment of antityphoid and paratyphoid vaccine, together with sanitation of water and food supplies, have practically annihilated these diseases. The future may bring about the complete eradication of diphtheria, scarlet fever, whooping cough, and possibly all the exanthems; while yellow fever, typhus fever and all plagues are falling before the gigantic march of preventive medicine, based on bacteriologic discoveries.

This has been the contribution of the physician to the march of human progress. Truly, neither the physician of the present nor the physician of the future need ever blush when contemplating his professional heritage.

CHANGES IN PRESENT-DAY MEDICAL PRACTICE

We build on the experience of the past. The rapid strides in medical discoveries of the last two generations, together with the more practical employment of sanitation and preventive medicine, have already effected great changes in the actual duties of the practicing physician. The daily round of our immediate predecessors was made up largely of the treatment of infectious and contagious diseases. The day-book of the family physician usually recorded visits to families for the treatment of measles, scarlet fever, diphtheria, typhoid fever or malaria only. He was educated to treat disease. He knew little of preventive medicine, sanitation or hygiene, nor did his medical education provide such knowledge. Older living practitioners know of the changes which mark the new era only by keeping abreast of the times.

National, state and municipal departments of health have gradually become powerful and controlling factors in preventive medicine, sanitation and hygiene. Health and welfare organizations, both national and local, have also invaded the field of preventive medicine. Great industrial organizations have introduced various health measures, believing it to be for their own best interests from an economical standpoint, as well as for the benefit of the hundreds of thousands of employees. Pay clinics and group practice have made some slight imprint on the modes of practice of today. Furthermore, the publicity work of all these agencies, together with that of our own Association, has gradually created a demand from the public for more information regarding personal health. The outcome of these measures has led to confusion regarding not only the present but also the future of medical practice. But the confusion of the present need never become chaos in the future, provided the medical profession prepares to meet the demands of the patients of the future.

HEALTH EDUCATION FROM THE STANDPOINT OF THE PUBLIC

The new era in medicine which the physician of the future must be prepared to enter must also rest on the foundation of a wide and comprehensive plan of personal and public health education. Professional policies, narrowly conceived, can never successfully oppose the rightful interest of the public. The failure properly to educate the public regarding the achievements of medicine and its importance in the preservation of life and the prevention of sickness may be considered as such a policy.

The editors of great daily newspapers and magazines, the newspaper syndicates, and university and public school teachers are calling on the medical profession as never before to enter this field. They properly contend that the educated physician must remain the source of personal and public health education. The *Saturday Evening Post* recently said that the "science of medicine, as far as laymen are concerned, is the most tongue-tied of all the learned professions." It called attention to the difficulties surrounding the scientific vocabulary of medicine as a means of teaching the public, and the shrinking attitude of the medical profession toward the lay press. Then followed the statement:

> The enlightened physician has a great body of news of the highest importance to communicate to nonmedical readers. When the medical profession becomes more fully awake to its responsibilities in this field, it is to be hoped that it will perceive the gravity and importance of its problem and attack it in force over a nation-wide front. Some national body, such as the American Medical Association, which has made such a good start along these lines, ought to take up the matter in a big way and work out a comprehensive program which would unify the efforts of the agencies already in the field, and cover the lay press of the whole country.

These friendly criticisms are perhaps well deserved. Our answer is that organized medicine has already entered this field. Considerable progress has been made in overcoming the reticence of medical men when called on to prepare health talks for audiences or the radio, or to write articles for lay publication. The prejudice that has existed against these measures is being dispelled. If the radio had been available during the ministry of the Great Physician, he would have made it hum and thrill while it adroitly advertised his message. The radio likewise should serve the physician and be made by him to illuminate his gospel of good health. Medical men now prepare articles for magazines, for the radio and for the public press covering all the phases of medical knowledge. I am proud to state with the greatest emphasis that the medical profession is well able to supply the brains for any and all nation-wide efforts for individual and community health education that the great business publications and the advertising world will undertake to promulgate and finance. This statement is the challenge of organized medicine! I pledge its fulfilment so far as lies within my power, and I sincerely hope that influential laymen of our country will accept the challenge.

Physicians until recently have contributed insufficiently to public health education. Today every licensed physician is being urged to prepare himself to teach his own patients the principles of health. Sufficient progress has already been made to warrant the statement that the field of public health education must and should be invaded by the physician. Organized medicine has approved this measure. The House of Delegates of the American Medical Association is on record as favoring every measure of public health education, including periodic medical examinations of the supposedly healthy. Two years ago the Board of Trustees entered this field on a larger scale by establishing *Hygeia,* a monthly public health journal published distinctly for the lay public. *Hygeia,* devoted to individual and community health, has already qualified as the leading public health journal of America. Its columns contain information of the utmost value covering the whole field of medicine. The lay reader is told what to do and what not to do regarding health affairs, and every issue contains exposures of vicious nostrums and quackery. Clip sheets from every issue of *Hygeia* are furnished to hundreds of newspapers, so that already millions of our people are receiving this direct and valuable health service.

Furthermore, many of our great newspaper syndicates, great daily newspapers and reputable magazines refuse to publish any material pertaining to health except on reliable medical approval. The propaganda of quackery and vicious nostrum advertising are refused by these great publications in the interest of the public health. Indeed, in health matters, many of these publications rely constantly on the advice received from the American Medical Association headquarters. Radio instruction in public health is rapidly increasing as a result of definite programs arranged by state and county medical societies. Other legitimate public health agencies are also active in this field.

PERIODIC PHYSICAL EXAMINATION

Periodic physical examination of the supposedly healthy is a public health measure that has the approval of the medical profession. The members of state and county medical societies are being urged not only to undertake the actual work of examination but to promote this healthful measure. The task of educating the one hundred and twenty million people of our country in personal and public health matters is stupendous, and its promulgation will require the combined efforts of medical men as teachers, of influential laymen and great publications as promoters. Physicians believe that whenever this great task shall have been accomplished in any nation, state or community, the average life of the inhabitants involved will be increased at least another seven years over the twenty that have been gained in the last half century.

Knowledge of the great principles involved in the preservation of health and of the great historical proof of preventive medicine will lead legislators and others in responsibility to protect every community against the blandishments of unlicensed quackery, the enmity of antimedical propagandists, and the evils of nostrum medication.

Public officials are already beginning to appreciate their responsibility regarding public health measures. In his recent message to the New York State legislature, Hon. Alfred E. Smith, governor of New York, proclaimed that "one of the great functions of government is the preservation of public health." He further said:

> I renew the recommendation of a year ago that careful consideration be given to the protection of the people of the state from unlicensed and unqualified persons practicing medicine. The cooperation of the medical profession is an essential factor in the protection of the public health, as well as in the care of the sick. A very large part of modern public health is urging people to get the advice of their physicians before serious and perhaps incurable conditions have developed. Such effort comes to naught if unqualified persons are allowed to hold themselves out as physicians. The subject is a difficult one, but the state of New York should take the lead in establishing high standards of medical practice, and providing a practicable plan for their enforcement. It is a matter of justice to qualified physicians and of protection to the public.

Let us hope that all state governors and all legislators will emulate the fine example of humanitarianism set by the governor of the Empire State.

HEALTH EDUCATION FROM THE STANDPOINT OF THE PHYSICIAN

The proposed campaign of public health education will surely create a demand for new contacts between patient and physician. Physicians must give a new significance to the word patient, for in the new order of things both sick and well people must and will be recorded in the lists of their physicians. In one of his recent addresses, Dr. George E. Vincent has called attention to the demands which this newly informed public is likely to make.

"They will demand that their needs should be met," he has said, and he warns that unless the medical profession shall organize to meet the demand in the proper spirit, various forms of state medicine are likely to become the order of the day. "No thoughtful person can welcome the extension of state medicine beyond the legitimate and necessary field of public health activity, but if private initiative and voluntary cooperation fail, it may be impossible to resist the demand for governmental intervention" in the practice of medicine. In other words, the state may be called on to organize and control not only methods of medical treatment but also the financial remuneration of the physician. I believe that this is unnecessary, but it surely will come unless we ourselves give heed to the coming needs and formulate our modes and methods to meet this demand in the spirit of true medicine. For medical agitators to stand on the housetops and shout defiance to state medicine will never solve a problem which can only be solved by perfecting a better way. The better way is to promote by precept and example the vast importance of maintaining the personal relationship of physician and patient. This is an essential fundamental in medical practice. For this principle, which the medical men of wide vision are contending today, no brighter example can be named than the late Sir James Mackenzie. He was a far sighted student of mankind who devoted the later years of his life to preaching this beneficent gospel.

Wilson, a disciple of Mackenzie, in "Pygmalion, or the Doctor of the Future," outlines a most vivid picture of the spirit of medicine advocated by Sir James Mackenzie, emphasizing that the intimate relationship of the coming medical man with his patient is to become more intimate than our present-day leaders in medicine have demanded. "Once upon a time," he says, "the priest was the doctor," but, "tomorrow the doctor may well have become the priest, in a new sense of the word." Not deprecating the necessary scientific preparation for his calling, this physician of the future must be "a humanist, a man with the widest and deepest possible knowledge of human nature, and the profoundest possible understanding of human motives. He will be a cultured man, ripe in intellectual attainments, but not lacking in emotional sympathy, a lover of the arts as well as a student of sciences. This is, indeed, no more than a projection into the future of a gracious figure of the past—for the great physicians of other days were all, likewise, great citizens of humanity." There must be less of the machine or mechanical physician and more of the individual.

Our great leaders in medicine have emphasized fully the fact that this physician of the future, if he expects to meet the new demands in such a manner as to prevent the unfortunate entry into the practice of medicine of so-called state medicine, must prepare himself educationally, morally, psychologically and sociologically, to make the painstaking intimate personal contact with his individual patient so effective, outstanding and unassailable that no other form of medical practice will be permitted by the layman himself.

What have I described? No new word need be coined for the answer. The future health needs of the public can best be supplied by a more humane, painstaking, better qualified, general practitioner of medicine. The family physician should remain the foundation of medical service. His outlook, functions and training need modification to meet changing needs. The field will be great and the opportunity for service boundless. The loyal service of the ideal general practitioner of medicine will go far to limit the advent of insurance methods of treatment, state systems, industrial groups, and other socialized principles which the true psychologists and humanists in medicine look on as mechanistic, soulless, bureaucratic, card index systems, discounting the spirit of individual relationship characterized by the better way.

The gospel of good health is based largely on the principles of preventive medicine. Our Association endorses every proper method for promoting all phases of preventive medicine. Periodic examination of the apparently healthy is one of our projects which promises well for the future as an important agency for preservation of individual good health. The American Medical Association is pledged to this measure, and state and county societies are rapidly becoming alive to its importance. Sufficient progress has already been made to demonstrate the fact that many of the illnesses of life are unknown to the patient during the incipient stages. This procedure enables one's physician to detect the first danger signal of any form of disease and to cope with it during its incipient and curable stage.

This family physician must educate his patients and community in preventive medicine and be to some extent a health administrator. His chief rôle and his chief service will be to keep his patients well. Evidently, such service can be made possible only by maintaining intimate, clinical information, well recorded, regarding every man, woman and child who seeks his service. And every man, woman and child in every community should have his health recorded in the files of his family physician. Too many of our inhabitants worry through life with only fairly good health, and while they accomplish their daily duties, these fairly well persons may never know the exuberance and happiness of perfect health. Hence, one goal of the future practitioner of medicine will be the attainment and maintenance of exuberant health, which is the inherent right of every person. A higher average of overflowing good health means a higher average of happiness, comfort, usefulness and economic value of the individual. The superman will never materialize without superhealth.

THE EDUCATION OF THE FUTURE PHYSICIAN

Fundamentally, the business of the undergraduate medical school is to teach scientific medicine. The application of the science of medicine on the part of the physician constitutes the art of medicine, knowledge of which should be supplied by the undergraduate curriculum. At the outset it should be clearly affirmed with the fullest emphasis that the practice of medicine is in no wise a business, and those who purpose to enter this field of service should remember that their material interests must always remain a secondary consideration and that its emoluments may never be reckoned in terms of finance. The education of the physician of the future must provide instruction in the art of medicine as well as in the science of medicine—not less of science, but more of the art is the educational need of the hour.

This view of medical education of the physician presages the future output of medical men whose scientific thinking will smack less of the mechanical, less of the technic of the laboratory, and more in the terms of the humanist. He must be taught to think more in terms of life, health and humanity than of disease and death. The medical education of the present places too much emphasis on the material and too little on the spiritual phases of medical practice. The student of medicine must be taught how to care for and advise the man as well as the patient. To this end, nothing need be done to disturb the high standards of medical education which the American Medical Association has set. It is necessary, however, that greater elasticity be given through proper modification of the present curriculum and policies of medical education.

The student should come in contact in the ambulatory department and at the bedside with patients for self-study under proper guidance and control. His course should include neurology, psychiatry, dermatology and the study of the diseases of children. It should also include instruction on the principles of both general and special surgery. A reasonable time should be devoted to ophthalmology, to otolaryngology, and to genito-urinary and other special diseases.

I find myself in agreement with Billings that the ideal general practitioner "must have a good knowledge of general and physiologic chemistry, of human anatomy and physiology, of pharmacology, of general pathology with constant training through the four years of residence in morbid anatomy, of epidemiology, immunology and psychology. In the clinical branches he must have the training of his brain, special senses and hands in the recognition of disease. He must learn to use the simple diagnostic aids in the form of instruments and laboratory tests. With this knowledge of the methods of diagnosis, he must have constant and daily opportunity to study disease as expressed in the ambulatory and ward patients. He must have an opportunity to observe the etiologic relations of occupations, environment, social conditions and other factors to disease. He must learn and recognize the importance of community as well as individual disease. He must have the opportunity to observe the results of medical treatment and management and the final condition of the patient after operative surgery. He must have an opportunity to witness minor surgical operations, emergency surgery, and especially to have practical training in the treatment of fractures of the bones and dislocations." In the hospital he should have an opportunity for the practical study of dietetics and of dietotherapy. He should have practical experience in the measures of disinfection in the sickroom and especially in the control of communicable diseases. "Finally, in addition to the educational qualifications, both academic and medical, the family physician must be a man of character. His daily life must be a practical expression of honesty, morality and resourcefulness in service to his patients. He will have a due consideration of his own health and responsibilities, and at proper periods will play as he works with well directed energy, giving and asking half the road and fair play."

That these changes in the curriculum may be brought about, influence should be brought to bear on the state licensing boards to abolish the nonsensical requirement of a stated number of hours of study in each branch of the curriculum. Obviously, a four year course of study of medicine, preclinical and clinical, is not too long, particularly in view of the fact that every student should receive additional common sense instruction in public health, preventive medicine, psychology and sociology so far as the term applies to the necessary alliance of medical and social sciences in the prevention and palliation of disease.

Every undergraduate medical school should make the necessary changes in the undergraduate curriculum to provide for these additional subjects. The curriculum should further provide instruction in principles of professional conduct and the highest ideals of medical ethics.

If our future practitioner fails in these things, his "place in the sun" will progressively diminish and his rôle will be invaded by industrial, state and various group practices which will be a great disadvantage to our inhabitants. The family physician should remain the foundation of medical service.

In view of these added requirements in the education of the future physician, it is unthinkable even to contemplate any lowering of the standards of medical education. Nor should a limited medical training be approved for men who might be willing to practice in rural communities. Any claim for a limited medical training is fallacious in reasoning and untenable, for the reason that the best in medical care is none too good for our lowliest inhabitants, no matter where they reside. It is sometimes argued that physicians of mature years, graduates of a former generation, have been successful even though the educational requirements of that day covered not more than two or three years. But it must be remembered that this was the full medical education for its day, and the graduates of that day have reached distinction in the profession and have made valuable contributions to medicine, surgery and pathology, not because of their limited medical education, but in spite of those limitations.

It is true that in certain limited areas in our land there is some scarcity of physicians. It is also a fact that for some years, particularly during the World War period, fewer men entered the medical schools; but soon after the war the numbers began to increase, and, according to the report of the Council on Medical Education and Hospitals of the American Medical Association, the higher entrance requirements are not preventing students from entering the field of medicine. The total enrolment of medical students in the United States since 1919 has increased at the rate of about one thousand a year, and in 1925 the approximate total enrolment of medical students in this country was 18,368. The proportion of students who are either partially or wholly self-supporting during their medical course is as large now as it was in the former days. Furthermore, the majority of the medical schools of the country are never able to accept all the students who clamor for admission. Possibly a larger number of medical schools should be provided in order to educate the number necessary to meet the needs of communities.

In view of the great expense involved in the maintenance of our medical schools, and in view of the fact that a large proportion of this expense is a contribution from philanthropic sources, every school should enroll the largest possible number of students. No school should reduce its enrolment to less than fifty students in a class, and the larger and better equipped schools should increase the number further to at least eighty or ninety to a class. Furthermore, the undergraduate medical school should limit its teaching to the output of all round qualified general practitioners of medicine only, and it should in no sense attempt to prepare men for the various specialties. Preparation for all the specialties should be entirely dependent on graduate schools of medicine. So far as our country is concerned, courses for specializing may be secured through graduate medical teachings in the universities and postgraduate schools. The courses for the majority of the specialties should cover a period of at least three years. In several of the specialties in this country, particularly the eye, ear, nose and throat, examination boards have been created for men who desire to be formally recognized by the national societies. Fortunately, it is no longer necessary for men to seek the graduate training in foreign countries. Under this scheme of education, every specialist must first receive the preliminary training required by the general practitioner of medicine.

Careful estimates would indicate that properly qualified general practitioners of medicine, aided by moderate home laboratory facilities, will be able to make a correct diagnosis and give all necessary instruction and treatment to at least 80 per cent of all the people who seek his aid, while 20 per cent of specialists, including internists and general surgeons, all thoroughly educated and trained, will be ample in number to care for the sick who need highly specialized service. Furthermore, the same proportion will to a large extent hold true of those who require hospital and special laboratory service.

Regarding the distribution of physicians throughout the country, it is a fact that the urban population has rapidly increased and now is in excess of the rural. This proportion of the general population is emphasized to a greater degree in the distribution of physicians. There are various explanations of this fact, the chief of which are the advent of the automobile and better living conditions, educational, social and otherwise, in the larger towns. "The properly trained and educated young general practitioner, the product of the medical school which has made its curriculum elastic and modified to make a practitioner, will be fit to practice in either the city or the country. To induce him to go to the country will require improvement in social and educational opportunity in rural districts. This is rapidly coming about, but needs stimulation through cooperative endeavor from the medical profession, educators of the country and other agencies who will bring about better schools and facilities for social enjoyment."

NEED OF HOSPITALS

Time will permit only a brief mention of the hospital as a necessary facility in medical practice. At present, 25 per cent or less of the practitioners, both city and country, have hospital facilities. Hospitals or similar facilities for the application of the refinements in diagnosis and treatment should be available in all communities, and particularly in rural districts. At present it seems somewhat difficult to supply proper hospital facilities in many rural communities, but our proposed extensive program of public health education should lead the enlightened laity to meet this demand. Every physician should be in contact with hospital facilities and experience—his progress in his profession depends on it. In every instance, particularly in rural communities, open staff organization is preferred; but hospitals connected with medical schools must necessarily be closed-staff organizations. It is possible that in other hospitals the open-staff organization could be made practicable by having a so-called executive staff or regular attendants in all departments who would be responsible for the character of the professional conduct of the hospital, and this staff would be supplemented by an auxiliary or associated staff properly classified and made associate members of the executive staff departments. This would afford every worthy physician of the community a hospital connection, but he would be obliged to follow the regulations of the hospital made and adopted by the executive staff.

CONCLUSIONS

May I venture the following conclusions and opinions:

The scheme of undergraduate medical education should be reconstructed to include in its curriculum as a prominent feature the science and art of health conservation, and the art of applying the principles of the science of medicine through the personal relationship of the physician and his patient. The undergraduate student must be trained to treat the body from the standpoint of health as well as that of disease.

These added requirements to the educational program of the future physician emphasize the argument against any lowering of the standards of medical education or lessening of the time involved in the teaching process.

Public health education is an outstanding need of the hour. The gospel of personal and community health is complex. It should be promulgated by health departments and agencies, by lectures, radio and film; but it will never reach its highest efficiency until it includes a maximum of direct personal instruction by properly qualified family physicians.

The patient of the future, in view of his perfected health education, may be expected to derive from it a wise judgment which will lead him to seek the continued advice and counsel of his personal physician. Furthermore, in view of our perfected system of individual and community health education, cults and other menaces to public health, all of which are founded on theories for the most part baseless and futile, will gradually disappear before the rising sun of enlightened public opinion.

The ideal family physician of the future by training, by experience, and by expert knowledge of health conservation will derive a potential power which will qualify him to control and direct the health problems of men.

The family physician of the future must have proportionate representation in the councils of his profession. No specialty or combination of specialties, not even general surgery, should be permitted to dominate the health affairs of a community or of a nation.

It is true that the service rendered by a physician may not be considered in terms of finance, but in no sense should our physician of the future offer this as an excuse for slothfulness in the management of his business affairs. Every detail of his newer service in the prevention of disease is of great value to his patient. Health education and conservation are services of value even greater to the patient than the sums paid for helping the body to repair the ravages of disease.

The maintenance of individual practice in the person of the general practitioner or family physician is of the utmost importance for the survival and continuation of the family home as the foundation of the nation.

Finally, let us hope that the physician of the future will be fully conscious of the vastness of the causes which he must advocate and the usefulness of the deeds he must accomplish; that he may have wisdom, poise and capacity of understanding that will breed in his patient an extraordinary confidence and esteem; that he may have a vision of a healthier, happier world which will blossom into unheard of activity. May we hope that to this end he will dedicate himself "through service to all that will advance and maintain and increase the sum of human happiness."

Every man who looks toward the future is charged with being a dreamer. But the verdict of history has always been that the onward march of science, religion and civilization has been led by dreamers. I have ventured modestly to tell my dream, knowing that it will find a thousand responsive cords in the hearts of my colleagues whose ambition and passion is to serve our fellow-men.

> Who dreams shall live. And if we do not dream
> Then we shall build no temple into time.
> Yon dust cloud, whirling slow against the sun,
> Was yesterday's cathedral, stirred to gold
> By heedless footsteps of a passing world.
> The faiths of stone and steel are failed of proof,
> The king who made religion of a sword
> Passes, and is forgotten in a day.
> The crown he wore rots at a lily's root,
> The rose unfurls her banners o'er his dust.
> The dreamer dies, but never dies the dream.

Though Death shall call the whirlwind to his aid.
Enlist men's passions, trick their hearts with hate,
Still shall the vision live. Say nevermore
That dreams are fragile things. What else endures
Of all this broken world save only dreams!

LYMPHOBLASTOMA (MALIGNANT LYMPHOMA)

AGE AND SEX INCIDENCE, DURATION OF DISEASE, AND THE EFFECT OF ROENTGEN-RAY AND RADIUM IRRADIATION AND SURGERY

GEORGE R. MINOT, M.D.
AND
RAPHAEL ISAACS, M.D.
BOSTON

(Concluded from page 1189)

INFLUENCE OF AGE AND SEX ON DURATION

Age and sex influence the duration of the types of lymphoblastoma under discussion, as well as the acute and chronic forms of lymphatic and myelogenous leukemia. These factors are to be recalled in considering the effect of therapy.

The data show that among the males the chance for a long duration of lymphoblastoma is definitely greater for those over 34 and under 65 years of age than for those below 25. For the age periods 0-14 and 15-24, about 75 per cent of the males died within 2.5 years, and only 5 per cent lived six or more years after the onset of illness. This is in contrast to the facts that 63 + per cent of both those aged 45-54 and 55-64 died within 2.5 years, and 18 and 8 per cent of each group, respectively, had their disease for more than six years. Figures of the same sort for the two decades between 25 and 45 are much alike and intermediate between those for young and relatively old ages.

The females in the age groups 0-14, 15-24, etc., up to the age of 55 showed, except in one group (25-34) a lower or equal incidence than males for a disease duration of 2.5 years or less. The lowest parcentages were 50, 57 and 52, respectively, for the ages 0-14, 15-24 and 35-44, and 30, 14 and 27 per cent, respectively, for the cases at these ages lasting six years or more. None of the females in the age groups 25-34 and 55-64 had their disease more than six years, and 77 per cent in the latter group died within 2.5 years after the initial symptoms. Comparable figures for the women from 45 to 54 are intermediate between those for the latter and the former groups.

The men 65 years of age and over had lymphoblastoma distinctly longer than the women of this age. At this time in life the factor "life expectancy" becomes an important one to reckon with when drawing conclusions. Thus, without taking into consideration persons over 65, the duration of lymphoblastoma in females tends to be longer than in males, being longer in men 35 years or more of age and in women under 25 years of age than in younger males and older women, except when the latter are from 35 to 44 years old. It may be noted that at the ages when females are relatively susceptible to lymphoblastoma the duration of disease seems to be longer than at other times. On the contrary, at the ages when the incidence in males is high the duration is apt to be shorter than when such is not the case. This rather peculiar difference is open to speculation. Averaged data concerning the duration of lymphoblastoma as related to age and sex are presented in chart 8, and the absolute number of cases composing the different age groups is listed in table 1. The chart shows in a different manner what has been recorded above.

The separate data for males and females treated and not treated with irradiation at different ages is relatively scant. No distinction in favor of irradiation can be observed between comparable groups, except that perhaps it influenced beneficially the duration of life of some males and females whose age was the same as those noted above to live the longest after the appearance of symptoms referable to lymphoblastoma.

To illustrate further that women live longer than men after lymphoblastoma develops, and that most of the cases of short duration occur in males, the percentage of males composing each group of patients having their disease for one, two, three, etc., years is shown in chart 9.

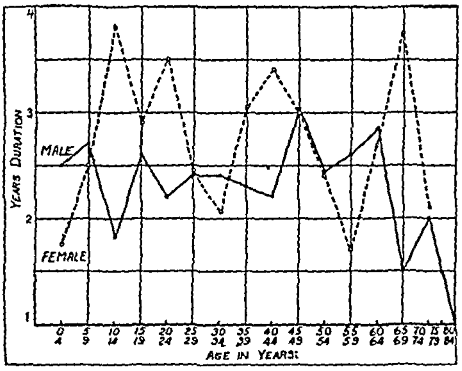

Chart 8.—Average duration of lymphoblastoma in those patients who had their disease less than ten years, with reference to the ages at onset, excluding one girl, aged 7, whose disease lasted nine years: solid line, males (277 cases); broken line, females (116 cases).

ESPECIAL INFLUENCE OF AGE ON DURATION OF DISEASE IN IRRADIATED AND NON-IRRADIATED PATIENTS

The duration frequency for three groups of cases, those lasting up to three, from three to six, and six or more years, correlated with the age of the patients is presented graphically in chart 10. The lines in this chart illustrate one more way of considering the influence of age on duration without taking into account the factor of sex or treatment. The data plotted similarly, but separately, for the irradiated and nonirradiated patients do show differences. There is, however, no distinction between that for the thirty irradiated and the thirteen that were not, who had their disease six years or more. The age distribution of the irradiated patients (158) with a duration of less than three years yields a curve very much like that in chart 10 for all cases of this duration. On the contrary, the nonirradiated patients (115) with a duration of less than three years have an incidence of about 7 per cent less for the age groups 0-14, and 15-24, and about 9 per cent greater for the age groups 25-34 and 45-54. Similarly constructed curves for cases of from three to six years' duration in which the patients were treated and not treated with irradiation differ considerably. That for the nonirradiated group (thirty-six patients) to the age of 54 is somewhat like that in chart 10 for all cases of this duration, the chief difference being an incidence that is 10 per cent less at the ages 25-34. Then there occurs at the ages 55-64 a rise to 23 per cent, or 10 per cent more than for all cases at these ages. The age distribution curve for the fifty-two irradiated patients with a duration of from three to six years shows a peak of 28 per cent incidence at the ages 25-34, rising rapidly from 6 per cent for those 0-14 years old and 15 per cent for the 15-24 age group. After the peak, the curve falls first slowly to 25 per cent for the 35-44 age group, and then rapidly, but constantly, to 5 per cent for the ages 55-64 years. Thus, the chief difference in the percentage distribution between the irradiated and nonirradiated patients with similar duration and like age was as follows: A greater percentage of irradiated than nonirradiated patients below the age of 24 had the disease less than three years, and a greater percentage of nonirradiated than irradiated in the age groups 25-34, and 45-54 had lymphoblastoma for this amount of time. The distinction between the three to six year cases is that there is a somewhat smaller percentage of irradiated ones in the 15-24 year group, a distinctly greater percentage in the 25-44 year period of life, and a much rarer occurrence at the ages 55-64 than for the nonirradiated patients.

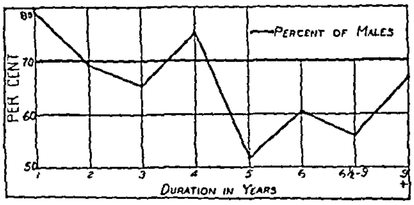

Chart 9.—Duration of lymphoblastoma: percentage of male patients having the disease for different periods of time. Of all 401 patients, 70 per cent were males.

Thus, it might be considered that irradiation had not influenced the duration of the cases lasting six or more years, yet had doubled the chances of persons from 25 to 45 years old having their disease from three to six years, and that it had influenced some groups less markedly, and others not at all or unfavorably. A similar tendency for irradiation to enhance apparently the chances of cases of chronic myelogenous leukemia to last from three to six years has been noted.[8] The treatment may be blamed for the greater incidence of irradiated than nonirradiated patients below the age of 24 with lymphoblastoma of short duration. The high frequency in young males of acute types of lymphoblastoma who happened to be irradiated more often than not may account for this great incidence of cases with irradiation. On the contrary, there is considerable evidence at hand that it is exceedingly easy for irradiation to cause a rapid dissemination of Hodgkin's disease, which composes the majority of the cases of lymphoblastoma in youth. Irradiation in what is often considered suitable therapeutic doses can lead to injury of the lymphoid tissue, and there occurs in Hodgkin's disease progressive sclerosis of this tissue, which is reflected in the peripheral blood by the characteristic lymphopenia. Thus, such treatment in undesirable amounts may intensify the process, so that an increased rate of progress of the disease ensues although a decrease occurs in the size of the irradiated lesion. Such overdosage may well account for the high incidence of irradiated cases of short duration in youth. A similar effect may occur in other types or groups of cases, but is not so distinct as for the patients with Hodgkin's disease.

TREATMENT OF CASES OF LYMPHOBLASTOMA OF SIX OF MORE YEARS' DURATION

A tabular view of sixty cases (thirty-nine patients dead[9] and twenty-one living) that have had some form of lymphoblastoma for six years or more is presented in table 2. The incidence among the 401 dead patients having their disease this length of time is about 10 per cent, which is essentially the same percentage as for those irradiated and those that were not. However, among the seventy-six living patients there are now twenty-one (27 per cent) who have had their disease this long. One has had no treatment of any sort, and the others have been treated with roentgen rays or radium, with or without surgery. Among the dead patients only ten (25 per cent) of the thirty-nine were considered to have been irradiated early so far as the character of the disease was concerned. Seven of these were treated also by surgical measures. There were three patients who underwent a therapeutic surgical operation early, but were never irradiated. Fifteen of the twenty-one living patients were irradiated first when their disease was in its early stages, and eleven of them had surgical treatment. Thus it may be noted that the percentage of patients that have had lymphoblastoma for six years or more approaches three times as great a figure for the living as for the dead. In turn, nearly three times as many living as dead patients received early treatment. Offhand, it would seem that the incidence of long duration had been increased by early treatment or modern methods, and, although this may be so, various other factors than treatment can account for this high incidence. The percentage frequency of cases lasting long is about the same for each of four groups of patients first coming to the clinic in four equal periods of time since the year 1900. This suggests that with irradiation and the improvement in irradiation methods the duration of the disease has not been influenced favorably. It must be appreciated that as time passes by there is an accumulation among the living patients of cases that are of particularly long duration. Likewise, the statistics must be considered with the knowledge that living patients accepted for study in the past year have been fewer than in recent years, and a tendency to select cases has probably occurred within two years, so that the total number of living patients may be proportionately few, compared to other times.[10] Also, unconsciously a greater effort has been made to keep track of cases of long than of briefer duration, so that perhaps all of long duration are listed and undoubtedly some of short duration excluded.

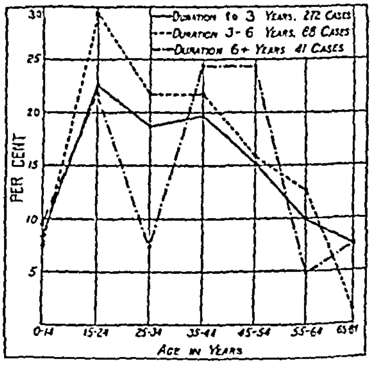

Chart 10.—Duration of lymphoblastoma: Curves showing age distribution of all patients (dead) whose disease lasted up to three years (272, solid line), from three to six years (eighty-eight, broken line), and six years or longer (forty-one, dash-dot line).

---

[9] Two of the total forty-one are not included.

[10] That this is so is shown by the fact that in the four months since the data were compiled the number having lymphoblastoma six years or more remains the same. On the contrary, fifteen new cases have been seen; and none are of more than four years' duration. Three of the patients previously alive have died. Thus, the living patients now total eighty-eight rather than seventy-six, which would decrease the percentage frequency of long cases among the living patients.

Following the initial symptoms of all these patients who had lymphoblastoma for a long time, the progress of disease as a rule was slow; and although surgical or irradiation treatment may have been undertaken in an early stage, this at times was a few years, even up to eight, after onset. There appears to be a definitely greater percentage of such instances among the living than the dead patients, so that by chance there are relatively more among the living whose disease remained local a long time before treatment was begun. Thus, therapy cannot be the sole reason for the unusual duration. The type of case that naturally lasts long is the one with a slow rate of progress early, spontaneous remissions, and apparently with the initial lesions developing particularly in parts of the body readily accessible for therapy. This permits a good opportunity for diagnosis before the disease is advanced, and thus treatment may be given at a desirable time. It is just such cases that are frequent among this group of living patients treated early in their disease. In view of the control series of cases, together with other aspects referred to above, it certainly seems as if treatment had not played the entire part in increasing the incidence of cases of long duration among the living, eleven of whom at present appear healthy.

TABLE 2.—*Lymphoblastoma of Six or More Years' Duration*

Type of Case; Number; Sex		Duration			Treatment (Often Long Periods Without Any)				
		9 Years or More	5 or More Years after Pathologic Diagnosis	Location Where Lesion First Noted; Number of Cases	Arsenic or No Therapy	Stage of Disease	Surgery	Surgery and Roentgen-Ray or Radium	Roentgen-Ray or Radium
Hodgkin's	19*	4 cases (3 ♀);	15 cases;	Neck 16	3	Early	2	7**	1
Male 8		longest,	longest,	Axilla 2		Middle	0	0	3
Female 11		17¾ years	13 years	Groin 1		Late	0	0	3
Lymphosarcoma	23†	6 cases (3 ♀);	16 cases;	Neck 10	1	Early	2	10 (roentgen-ray late in one)	3
Male 12		longest,	longest,	Tonsil 1					
Female 11		16 years	13 years	Nose and sinus 2		Middle	0	2	3
				Eye 2		Late	0	0	2
				Abdomen 6				(10 living)	(1 living)
				Groin 2					
Pseudoleukemia	13‡	5 cases (1 ♀);	6 cases;	Neck 8	5	Early	1	0	3
Male 10		longest,	longest,	Groin 2		Middle	0	0	2
Female 3		12 years	7 years	Spleen 2		Late	0	0	2
				Abdomen 1					
Lymphoblastoma, unclassified	5§	1 case (1 ♀)	2 cases;	Neck 2	1	Early	0	1	1
Male 3		longest,	longest,	Eye 1		Middle	1	0	0
Female 2		3 years	6 years	Axilla 1		Late	0	0	1
				Abdomen 1					

Total, 60; male, 33 (55%); female, 27 (45%). Dead, 39; living, 21.

* In the Hodgkin's group the disease became slowly generalized. Spleen enlarged late. In thirteen cases abnormal nodes were in two locations within three years of onset; and in two cases within a year. In three others they did not occur in more than one location until five years or more. In one (eight and one half years' duration) of four living patients there have been no signs of disease for five years.

** In two, roentgen ray not for several years after surgical treatment.

† Twelve of the lymphosarcoma group are dead. One died of heart disease without recurrence of the lymphoblastoma. In one the disease remained confined to the head region, and in one almost entirely to the abdomen. The disease became generalized in nine; in one of which the original lesion was in the vicinity of the eye. It was generalized in four in from three to four years after onset, in two in five years, in three in from seven to thirteen years. Eleven are living. In four the disease is generalized and it began in the neck, abdomen or eye region. No recurrence has been noted in five patients whose initial lesions were in the neck for two cases, and in the rectum, nasal and eye region for the other three. The disease remains local in two cases; in the mediastinum of one, and in the pelvis of another. The spleens of these twenty-three patients were seldom enlarged more than slightly. Roentgen ray or radium often improved the patient's health greatly and caused rapid shrinkage of masses.

‡ In the cases called pseudoleukemia, frequently no treatment with roentgen ray or radium was given for from four to six years. Such treatment caused less striking effects than in the cases of lymphosarcoma. The disease became generalized in less than one and one-half years in all the cases of pseudoleukemia, except in one patient now living. Abdominal masses were present in all but one of the ten deceased patients. These masses were often present early in the disease, when the spleen was usually enlarged. Prominent symptoms usually did not appear until four years after onset of the disease.

§ In the unclassified cases of lymphoblastoma the disease became generalized in three, and in one remains confined to the eye region and in another to the abdomen.

Be this as it may, it does remain true and noteworthy that there is a high frequency among the cases of long duration of those treated early by surgery and irradiation, the latter being continued in a suitable manner. It becomes difficult not to believe that therapy does, at least sometimes, influence the duration of the disease. Even so, the facts might not be reconciled in this way; for it is true that similar cases, either with or without any irradiation or surgery, or such treatment only very late in the course of the disease, are alike in duration, and that among the cases of all types are some with long intervals, even years, between irradiation treatments.

A few notes are given regarding several cases to illustrate certain points, including how treatment must in all reasonable certainty be able to lengthen the life of a patient with lymphoblastoma.

Complete removal of diseased tissue by surgical measures was done early in very few cases. One boy, now 15, had the diseased nodes in his neck removed nine years ago, when no other enlarged ones were detected. The pathologic examination of the tissue undoubtedly shows lymphoblastoma and apparently of the Hodgkin type. A series of radium treatments was given during the two years after the operation. About a year after operation, there appeared slight enlargement of nodes in the vicinity of the scar, but none since. This boy has had no irradiation or especial treatment for more than six years and appears well in all respects. One woman with Hodgkin's disease, who had surgical and irradiation treatment early, showed at that time enlarged lymph nodes in various parts of her body, which fluctuated in size during the following five years. She has been given no irradiation in the last four years, and there have been no detectable symptoms or signs of disease during this time, except that her blood picture has shown a progressive lymphopenia. It must be recalled that with or without treatment of the patient symptoms may be absent for a number of years. It is believed that the boy may be cured of lymphoblastoma, but that this woman, especially on account of her blood picture, will develop serious symptoms before long. One can decide if he chooses that treatment has not affected the duration of either case, and somewhat similar cases without especial treatment make this assumption tenable.

Cunningham [11] has recorded a case of Hodgkin's disease of twenty-five years' duration. The longest duration of lymphoblastoma in the present series was seventeen and three-fourths years The patient was a girl, aged 12 at the onset of her illness, and she never was treated by irradiation or surgery. The diagnosis was established by microscopic examination of an excised lymph node thirteen years before her death. Intermittently for years there was swelling of nodes in the neck, with a slow involvement of other nodes and enlargement of the spleen Finally, two years before death, essentially all external and internal nodes became enlarged

---

[11] Cunningham, W. F.: Hodgkin's Disease: A Study of a Series of Twenty-Five Cases, Am. J. M. Sc. **150**: 868 (Dec.) 1915.

Among the patients whose disease was termed lymphosarcoma is one who had a tumor of this sort removed by resection of a portion of the small intestine at a time when no other evidence of disease existed. Following the operation, this patient had no symptoms for seven years Then there appeared multiple masses in the abdomen with enlargement of nodes in the groin, and she died nine years after the onset of symptoms Similar instances are reported in the literature,[12] but none with such a type of lymphoblastoma have lived so long after initial symptoms except following surgical treatment. Thus it seems logical to attribute the long duration to surgical intervention. Another patient, one with a lymphosarcoma of the rectum, appears now entirely well, after very complete treatment with irradiation that was last administered five years ago A somewhat similar state of affairs holds for a patient whose lesion has been confined to the neck, and for another in whom the disease was in the nasal region. The mediastinal case of long duration, first treated with roentgen rays early, has been reported by Holmes[13] After the cases in table 2 had been listed, it was noted that no surgical procedure was undertaken on those of long duration called pseudoleukemia. The reason for this is simple to understand; namely, this type of lymphoblastoma becomes generalized early, so that at the time the patients are seen or a diagnosis made there is no single local lesion for operation.

DURATION OF CASES IN WHICH IRRADIATION WAS DONE EARLY

A survey has been made concerning the duration of lymphoblastoma in cases selected because it was believed that the patients had had early and adequately continued irradiation treatment. These patients are now all dead. Fifty-four were selected to compose one group because they first received irradiation early so far as the disease state was concerned; i. e, when relatively local, when toxemia signs and symptoms and the like had not occurred A second group of eighty-one cases was chosen because irradiation was begun before 33 per cent of the duration of each patient's illness had occurred (i. e., for example, two months or less for disease with a duration of six months; two years or less for disease with a duration of six years)

The frequency of the different durations of lymphoblastoma for each of these two groups is contrasted in chart 11 with that for (1) 184 cases treated with irradiation late in the course of the disease so far as its character was concerned, (2) 157 cases treated with irradiation after 33 per cent of the disease duration had taken place, (3) 163 cases not treated with irradiation

The length of the disease in those irradiated and not so treated has been shown for half-year periods in chart 6, and is shown in chart 11 for yearly periods. No further comment of a comparative sort on these data is required

The data yield curves for the different groups of irradiated patients that are very similar except for those treated early so far as the state of their disease was concerned. This would suggest that, no matter whether irradiation is begun when a small or large percentage of the duration of disease has occurred, the influence of this treatment on duration was nil. On the contrary, the data for the fifty-four cases treated with irradiation early so far as the disease state was concerned indicate that the chances of these patients having their disease long were relatively great. However, one is forced to recognize that it is a case of this type that is apt to last a long time without any special treatment These fifty-four cases usually developed slowly, so that though a long time occasionally occurred from onset to diagnosis, during the interval progress was slight. In many other cases a more rapid progress occurred, and though it may have taken the same long time for the patient to *obtain a diagnosis, the disease, unfortunately, was relatively* advanced and so treatment was not begun until late Furthermore, any case among those treated by irradiation early so far as the disease state was concerned can be paralleled by a similar case of like duration that was not treated with irradiation or not given such treatment until a far-advanced stage of the disease had been reached Thus, in spite of the fact that patients irradiated when lymphoblastoma had progressed but little have lived with their disease relatively long, there are reasons for not attributing this desirable circumstance to the therapy alone.

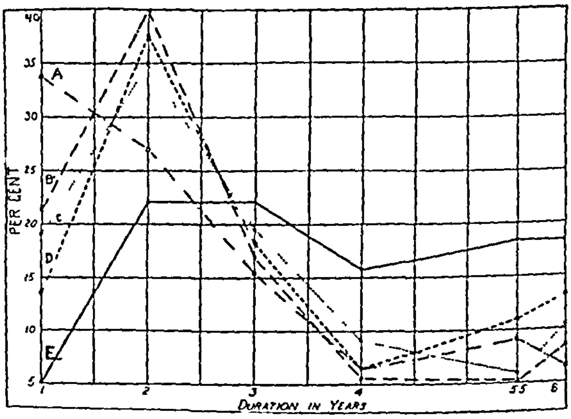

Chart 11 —Percentage frequency of the duration of lymphoblastoma in groups of patients selected with reference to when roentgen ray or radium treatment was first begun *A*, 163 patients not treated with roentgen ray or radium, *B*, 184 patients treated late, with reference to the character of the disease, *C*, 157 patients not treated early, irradiation therapy started after 33 per cent of the disease had passed, *D*, eighty-one patients irradiated early (38 per cent of all irradiated) in that treatment was begun before 33 per cent of the total duration of the disease (in each case) had occurred, of the eighty one, 22 per cent had surgical treatment, *E*, fifty four patients irradiated early (22 per cent of all irradiated) so far as the disease state was concerned; nineteen of the fifty four (35 per cent) also had surgical treatment

CONCLUDING COMMENTS ON THERAPY

There is, of course, no question but that lymphoblastoma lesions may regress in size either spontaneously or as the result of irradiation There is evidence also that the administration of arsenic, perhaps especially in the form of one of the newer arsphenamine-like preparations, can influence favorably the patient and the size of his lesions However, this happens much more frequently and as a rule is more marked following irradiation than occurs naturally or after treatment with any drug. Likewise, though the lesions may remain small for from weeks to years, they are much more apt to do so for a long time when irradiation has been given than when it has not. Such treatment is undoubtedly valuable since it improves the patient's efficiency and alleviates symptoms. The present methods of irradiation are better than former ones because the dangers of heavy and too constant dosage have been learned, the amount given can be controlled accurately, and roentgen-ray sickness and undesirable effects on the marrow minimized. In spite of the fact that the statistics for groups of cases show that irradiation has not prolonged significantly the duration of lymphoblastoma, it does seem as if in certain instances it did so. Besides cases of this sort cited above, one cannot help being impressed by the fact that patients with lymphoblastoma and apparently near death constantly are seen to be relieved by irradiation, and at times even restored to apparently normal health. For example, large masses in the thorax may cause partial suffocation; the patient becomes desperately ill, and irradiation appears to prevent death at that time. Perhaps some extension of life can be attributed to such therapy when death is at hand from a mechanical cause, especially when developing relatively soon after onset, and that otherwise irradiation does not influence the progress of disease. This is similar to the prevention of death from starvation of a patient with cancer of the esophagus, by the administration of food through a stoma in the stomach. Although irradiation occasionally may influence duration desirably, it can also shorten life if not given wisely. The occurrence of such cases may counterbalance in the statistics the slightly increased duration of lymphoblastoma produced in patients with much mediastinal pressure and the like and perhaps in some first irradiated very early. However this may be, there is no definite evidence that irradiation has prolonged distinctly the duration when a group of cases is considered as a whole.

[12] Graves S Duration of Lymphoblastoma of the Intestine, J M Research **40** 415 (Sept) 1919

[13] Holmes G W, in Case Clinics of Massachusetts General Hospital, Case 10432, Boston M & S J **191**.783 (Oct 23) 1924

Neither roentgen rays nor radon should be given in a repeated, perfunctory, routine manner. The state of the patient, his blood, and the precise character of the case all require evaluation in order to give the most suitable irradiation. Also, we have noted that the basal metabolic rate may serve as a guide to treatment not only for cases of lymphatic leukemia but also for the other forms of lymphoblastoma. Irradiation seems desirable when the metabolism is elevated. This may occur when lesions are small and when treatment would not be considered wise so far as their size alone is concerned. Such matters are not for discussion here, but it is pointed out that although the statistical data have been obtained without taking into account the nature of the case as regards the location of the initial lesions or what parts of the body are prominently involved, there are some differences for the duration of lymphoblastoma according to the particular mode of onset and developments of the pathologic process. These differences do not appear to cause any essential change in the facts presented in the contrasted data, as the variety of types of cases composing contrasted groups were similar, except as have been described.

The value of surgical treatment of lymphoblastoma is not to be neglected. Surgical intervention relatively late in the disease is of very problematic use and best never be considered. However, it is logical, as Yates and Bunting[14] have shown, to expect benefit from complete, not partial, removal of the diseased tissue, especially in that type of case that appears to have a single seat rather than multiple places of origin. There is some rather definite evidence at hand that, following incomplete surgical removal of lymphomatous masses, the disease then may spread with greater rapidity than if no operation had been done, and wounds of such tissue tend to heal sluggishly. Unfortunately, the opportunity for radical surgical treatment early is infrequent, as these patients usually do not obtain a correct diagnosis for many months after the onset of their illness. It is, indeed, a striking fact that patients with lymphoblastoma, particularly when some external lymph nodes are but slightly enlarged, or none appear to be, form a group that puzzles many physicians. A correct diagnosis of a form of lymphoblastoma made only when a case is far advanced is vastly too common.

The data in table 2, as well as other information, do suggest that early complete removal by surgery of lymphoblastoma offers patients an opportunity for life extension and perhaps actual cure. Surgery most certainly is not to be employed indiscriminately, nor had it best be used for merely partial removal of lymphoblastomatous tissue in the body. Following operation, the administration to these patients of suitable irradiation appears wise.

SUMMARY

Four hundred and seventy-seven cases of all types of lymphoblastoma, excluding lymphatic leukemia, have been studied. Four hundred and one of the patients are dead; 238 were treated by roentgen-ray or radium irradiations, and 163 were not. Sixty-eight per cent of all were males.

The ages at which lymphoblastoma most frequently began were from 20 to 24, when most of the cases were of the Hodgkin type. The next ages when persons were most susceptible were from 35 to 39. At this time in life other forms of lymphoblastoma than Hodgkin's disease composed the majority of cases. Females tended to have the different forms later in life than males.

At all ages except at the age of puberty the number of males exceeded the females, and a relatively large percentage of women had the condition at or near the time of the menopause.

The duration of lymphoblastoma in the females was apt to be longer than in the males. It tended to be longer in men over 35 years old and in women under 25, than in younger males and older females, except when the latter were from 33 to 44 years of age.

Comparisons between the lengths of the course of disease in irradiated and nonirradiated patients do not indicate that such treatment significantly affects the duration of lymphoblastoma. It may do so in selected cases and yet can be blamed, in cases of short duration in the patients that were below the age of 24, for the greater incidence of those in which irradiation was given than those in which it was not.

The chances of lymphoblastoma lasting long were relatively great for those first irradiated when their disease was in an early stage. However, the duration of any such case can be paralleled by one given no special form of therapy.

Surgery probably can influence beneficially the duration of some cases of lymphoblastoma, particularly if it is employed early and thoroughly and is followed by irradiation.

The type of case usually treated early by surgery or by irradiation is apt to be the same as that destined by nature to last a long time.

tion of lymphoblastoma in the present series was seventeen and three-fourths years. The patient was a girl, aged 12 at the onset of her illness, and she never was treated by irradiation or surgery. The diagnosis was established by microscopic examination of an excised lymph node thirteen years before her death. Intermittently for years there was swelling of nodes in the neck, with a slow involvement of other nodes and enlargement of the spleen. Finally, two years before death, essentially all external and internal nodes became enlarged.

Among the patients whose disease was termed lymphosarcoma is one who had a tumor of this sort removed by resection of a portion of the small intestine at a time when no other evidence of disease existed. Following the operation, this patient had no symptoms for seven years. Then there appeared multiple masses in the abdomen with enlargement of nodes in the groin, and she died nine years after the onset of symptoms. Similar instances are reported in the literature,[12] but none with such a type of lymphoblastoma have lived so long after initial symptoms except following surgical treatment. Thus it seems logical to attribute the long duration to surgical intervention. Another patient, one with a lymphosarcoma of the rectum, appears now entirely well, after very complete treatment with irradiation that was last administered five years ago. A somewhat similar state of affairs holds for a patient whose lesion has been confined to the neck, and for another in whom the disease was in the nasal region. The mediastinal case of long duration, first treated with roentgen rays early, has been reported by Holmes.[13] After the cases in table 2 had been listed, it was noted that no surgical procedure was undertaken on those of long duration called pseudoleukemia. The reason for this is simple to understand; namely, this type of lymphoblastoma becomes generalized early, so that at the time the patients are seen or a diagnosis made there is no single local lesion for operation.

DURATION OF CASES IN WHICH IRRADIATION WAS DONE EARLY

A survey has been made concerning the duration of lymphoblastoma in cases selected because it was believed that the patients had had early and adequately continued irradiation treatment. These patients are now all dead. Fifty-four were selected to compose one group because they first received irradiation early so far as the disease state was concerned; i. e., when relatively local, when toxemia signs and symptoms and the like had not occurred. The average duration of lymphoblastoma in the 401 deceased patients was 2.76 years, yet about 10 per cent of both the irradiated and nonirradiated had the disease for six or more years. A greater percentage of the seventy-six living patients have had lymphoblastoma this long duration of time. Although among them the frequency of surgical and early irradiation treatment is greater than for the deceased group, the treatment by modern methods will explain at the best but partially the increased percentage of cases of long duration.

Irradiation is undoubtedly of great value to patients with lymphoblastoma; it alleviates symptoms, decreases the size of lesions, and improves the patients' efficiency, in spite of the fact that it does not appear to influence importantly the duration of the disease.

OBSERVATIONS ON THE ETIOLOGY OF TUMORS

AS EVIDENCED BY EXPERIMENTS WITH A CHICKEN SARCOMA *

JAMES B. MURPHY, M.D.
NEW YORK

In a series of papers published between 1911 and 1916, Rous[1] and his associates described a group of transplantable sarcomas of the chicken which could be transmitted from fowl to fowl by means of a cell free filtrate. The nature of these agents was not determined, but the natural deduction was that they belonged to the class of ultramicroscopic organisms. The main objection to this deduction was the high degree of specificity both in the animals affected and in the type of differentiation induced in the tissue. From these points it seemed more likely that the agents were closely associated with the mechanism controlling cell growth and differentiation than with an extraneous organism.

Recently, Gye[2] has reported experiments which he interprets as proving the presence of a living organism as the cause of malignant disease. According to him, this organism is active only in conjunction with a specific chemical factor which determines the animal species and tissue infected.

The basis for this theory is as follows: A piece of one of the chicken sarcomas mentioned above, when placed in a special culture medium and incubated in the absence of oxygen, in the course of a few days loses its power to produce a tumor. If, however, the clear supernatant fluid from such a "culture" is mixed with a fresh filtrate of the chicken tumor in which the tumor producing agent has been killed by chloroform, this mixture is now capable of inducing a typical malignant tumor of the chicken. Furthermore, similar "cultures" of rat, mouse and even human neoplasms in conjunction with the chloroform killed extract of the chicken sarcoma are equally potent in inducing a malignant change in the tissues of chickens. Gye reports that the organism of the chicken tumor may be subcultured through a number of generations and still be active when injected along with the so-called specific chemical factor. It is significant that these subcultures were made with the same type of medium employed for the initial "culture," but with the addition of a generous supply of embryonic tissue.

The fundamental nature of the problem involved has led us to examine the experimental proof on which this theory is based. The only source of the so-called chemical factor up to the present has been a filtrable chicken tumor. The supposed organism has been obtained from a variety of neoplasms, but in Gye's original publication no mention was made of control cultures of normal tissues.

The present report has to do with this point.

METHOD

Throughout the experiments we have attempted to follow in detail the methods used by Gye in his investigation.

Medium.—Hartley's broth was used as the base. To this was added 0.2 per cent potassium chloride and sufficient sugar to give a concentration of 0.7 per cent. The medium was tubed in 5 cc. amounts and sterilized. Then to each tube was added 1 cc. of fresh rabbit serum, and they were incubated for forty-eight hours to test the sterility.

Filtration.—The transmissible chicken tumor was the same one as that used by Gye in his experiments (chicken tumor 1). It was prepared in the usual way by grinding the fresh tissue with sand and adding about 50 cc. of Ringer's solution for each gram of tumor material used. The suspension was centrifugalized and the supernatant fluid filtered through a coarse Berkefeld filter (Gye used a sand and paper pulp filter).

The filtrate was placed in large test tubes in 10 cc. amounts, and to each was added from 0.15 to 0.2 cc. of chloroform, which was allowed to flow down the side of the tube so that a layer remained on top of the filtrate. In this condition the tubes were placed in a water bath at 36 C. for one-half hour, and then the filtrate and chloroform were thoroughly mixed and the tubes returned to the water bath for three hours. The amount of chloroform used was sufficient to insure a saturated solution with an excess, as shown by the fact that an appreciable amount was still present in the form of fine droplets in the bottom of the tube at the end of incubation. The chloroform was next boiled off in a vacuum at room temperature, and the fluid was ready for use.

Experiment 1.—A filtrate was prepared from a rapidly growing chicken tumor, and a portion of this was submitted to the chloroform treatment. An equal amount of the filtrate was added to the supernatant fluid of each of the following: eight day culture of chicken tumor 1; four day culture of chicken tumor 9,[3] and a four day culture of mouse placenta. Five cubic centimeters of each mixture was injected into the pectoral muscle of a Plymouth Rock hen. For control, 5 cc. of the chloroform treated filtrate was likewise injected into a hen. Thus the control received twice the amount of treated filtrate given to the test fowls. The activity of the untreated filtrate was likewise tested.

No tumor resulted from the injection of chloroformed filtrate alone, but rapidly growing typical sarcomas developed in the chickens receiving this filtrate mixed with the culture fluids of chicken tumor 1 and chicken tumor 9, and also with the culture fluid of mouse placenta. The latter tumor developed just as early and grew just as rapidly as did the other two.

Experiment 2.—The general technic of this experiment was the same as the foregoing. Of six chickens injected with 5 cc. of a mixture of equal parts of chloroformed filtrate of chicken tumor 1 and the supernatant fluid of a forty-eight hour culture of rat placenta, four developed typical tumors. Two of these progressed fairly rapidly, one grew slowly, and the fourth after a period of growth retrogressed following the removal of a piece for section. This last proved microscopically to be a typical sarcoma.

Of two chickens injected with 5 cc. of a mixture of equal parts of the chloroformed filtrate and the untreated filtrate of chicken tumor 9 (a nonfiltrable tumor), one developed a rapidly growing sarcoma of the type of chicken tumor 1.

---

* From the Laboratories of the Rockefeller Institute for Medical Research.

[1] Rous, Peyton: J. Exper. Med. **13**: 397, 1911. Rous, Peyton; Murphy, J. B., and Tytler, W. H.: A Filtrable Agent the Cause of a Second Chicken Tumor, an Osteochondrosarcoma, J. A. M. A. **59**: 1793 (Nov. 16) 1912. Rous, Peyton; and Murphy, J. B.: J. Exper. Med. **19**: 52, 1914.

[2] Gye, W. E.: Lancet **2**: 109 (July 18) 1925.

Two chickens inoculated with 5 cc. of the chloroformed filtrate, twice the amount received by the test chicken, showed no evidence of tumor.

Experiment 3.—The general technic was again the same. Each of four chickens received 5 cc. of a mixture in equal parts of chloroformed filtrate of chicken tumor 1 and the supernatant fluid of a five day culture of chicken embryo. Three developed tumors, two rapidly progressive with extensive metastases at necropsy, and one slowly progressive, the hen being still alive.

Three chickens received 5 cc. of a mixture of chloroformed filtrate of chicken tumor 1 and the fluid from a five day culture of rat placenta. Of these, one developed a progressive tumor.

For controls, two fowls received 5 cc. of the chloroformed filtrate, again, twice the amount given the test fowls. They have remained free from tumors.

There are several additional experiments of the same nature, not yet completed, in which tumors have already developed from the treated filtrates mixed with fluid from cultures of embryo and placenta. In all cases the chloroformed filtrate alone has proved inactive.

In all experiments, the cultures were incubated under strict anaerobic conditions.

Placenta and embryonic tissue were selected for the control culture for the reason that they share with malignant tissue the ability to utilize sugar in their metabolism in the absence of oxygen.[3] This seemed important in view of the possibility that the substance activating the chloroform treated filtrate might be a product of metabolism.

COMMENT

Apparently the power to activate a chloroformed filtrate cannot be considered as proof of the action of a living organism, for cultures of embryonic tissue or placenta are just as potent in this respect as so-called cultures of malignant tissues.

Two possibilities present themselves in explanation of the results attained. First, that the causative agent of the chicken tumor is in the nature of an enzyme-like substance which is inactivated by chloroform and may be reactivated by a diffusible substance from malignant tumors, embryonic tissues and placental tissues. The second possibility is that the chloroform treatment does not destroy but simply attenuates the causative agent to a point at which unaided it is too weak to induce a tumor but in conjunction with some injurious or stimulating substance supplied by the "culture" it becomes effective. The fact that a great excess of chloroform so completely destroys the agent that no reactivation is possible is rather in favor of the latter possibility. Further experiments are in progress to elucidate these points.

SUMMARY

Anaerobic "cultures" of chick embryo and rat placenta have proved just as effective as so-called cultures of malignant tumors in activating chloroform treated filtrates of a chicken sarcoma. The necessity of assuming a cultivated living organism in the interpretation of Gye's results is eliminated.

THE RELATION OF ANAPHYLAXIS TO IMMUNITY

STUDIED BY PASSIVE SENSITIZATION IN DOGS

W. H. MANWARING, M.D.
Professor of Bacteriology and Experimental Pathology, Stanford University School of Medicine
RALPH W. WRIGHT
AND
PHIL W. SHUMAKER
STANFORD UNIVERSITY, CALIF.

One of the debated questions in immunology is the relation of acquired hypersusceptibility to acquired immunity. Is hypersusceptibility an expression of an incompletely developed immunity, being possibly even a necessary integral part of the immunity mechanism? Or are the two processes wholly unrelated, independent expressions of toxic injury and bodily adaptation to foreign products?

Among serologists, the debate has narrowed down to a question of the identity or nonidentity of the specific precipitin and the so-called specific sensitizing antibody. Several observers have noted that the power of a rabbit antiserum to produce passive sensitization in guinea-pigs varies with its precipitin titer. Others have noted that in rabbits active sensitization is synchronous with the appearance of a certain definite amount of precipitin in the serum. Many serologists therefore believe that the sensitizing antibody and precipitin are identical, and that small amounts of precipitin give hypersusceptibility, larger amounts conferring immunity.

We have thought to throw light on this question by studying the relationship between the sensitizing antibody and the immune antibodies in the dog, an animal not yet used in such comparisons.

TECHNIC

To do this, one series of dogs was sensitized to horse serum by the routine method adopted in our laboratory.[1] A second series was immunized by from ten to twelve subcutaneous, intraperitoneal or intracardiac injections of 0.25 cc. of horse serum per kilogram of body weight, given at intervals of from four to six days. Transfusion tests were made from fourteen to twenty-one days after the final immunizing dose.

In dogs anaphylactic serums and immune serums usually gave approximately the same precipitin titer.

PASSIVE SENSITIZATION

Anaphylactic Donor.—If a normal dog is exsanguinated as completely as possible, and its blood volume restored by transfusion from an anaphylactic donor, the transfused dog becomes typically hypersensitive. Twenty-four hours later, on intravenous injection with 1 cc. of horse serum per kilogram of body weight, there is a typical fall in arterial blood pressure, typical contractions of smooth muscle structures, typical cyanotic engorgement of the abdominal viscera, and a complete loss of blood coagulability. Recovery is usually complete in from thirty to sixty minutes.

Immune Donor.—If in a similar way from 5 to 80 per cent of the total blood volume of a dog is replaced by transfusion from an immune donor, no suggestion of specific hypersusceptibility is conferred on the transfused animal. On a routine test, twenty-four hours later, there is no fall in arterial blood pressure, no engorgement of the abdominal viscera, and no reduction in blood coagulability.

---

[1] Manwaring, W. H.; Chilcote, R. C., and Hosepian, V. M.: J. Immunol. 8: 233 (May) 1923.

This differs markedly from published results with rabbits and guinea-pigs, in both of which a passive transfer of from 10 to 25 per cent of the total serum volume from an immune donor renders the normal animal typically hypersensitive, in many cases sufficiently so to give fatal anaphylaxis.

CONCLUSION

In dogs, therefore, the difference between the sensitizing antibody and the immune antibody is not merely a quantitative one. The two antibodies apparently have wholly different physiologic properties.

PRACTICAL VALUE OF EXAMINATION FOR ENDAMEBA HISTOLYTICA BY CULTURE *

J. H. ST. JOHN, M.D.
Captain, Medical Corps, U. S. Army
WASHINGTON, D. C.

The discovery of a successful method [1] for the cultivation of *Endameba histolytica* has given the medical profession a valuable aid in the management of amebic dysentery. The following exerpts from my experience may serve to exemplify the worth of the procedure.

1. Patient F. C., Walter Reed General Hospital, had had amebic infection for about ten years. Several years prior to his admission, a colostomy had been performed in a civil hospital for the purpose of treatment by irrigation. Motile amebas, containing red blood cells, were present in the stool and in the colostomy wound. Study of the movements and structure of the nucleus provided additional proof that the ameba was undoubtedly *E. histolytica.* Culture in this case was positive in twenty-four hours, and the ameba recovered was identical with that observed in direct examinations. By subculturing every forty-eight hours, this ameba has been carried in culture for the last four months.

2. Patient A. P. had had amebic infection. Physical examination and operation revealed a liver abscess, which was opened and drained. Many examinations of the feces had been made for amebas by the usual procedures, but none ever had been found. A culture of the feces, however, disclosed an ameba, typically *E. histolytica.* This ameba has been maintained in culture for the last three months.

3. In a survey of apparently healthy men, cultures of sixty-one stools were taken from as many individuals. Amebas corresponding in morphology to *E. histolytica* were recovered in six, an incidence of 9.8 per cent. Previous examinations by direct smear preparations were negative in five of the six instances. These amebas have been in culture for a period of two months.

4. In cultivation of a specimen received by mail, a stool, 48 hours old, contained a moderate number of cysts of *E. histolytica.* Motile amebas, *E. histolytica,* were recovered in culture at the end of twenty-four hours' incubation. The stool was placed in the icebox, and subcultures were taken after a lapse of eight days, when motile amebas were again recovered.

Theoretically, the multiplication of amebas in culture and their settling to the bottom by gravitation should give at one and the same time the equivalent of an examination of a large sample of feces by one of the methods of concentration. In practice, this is exactly what takes place. The practical value of this finding rests in the use of the cultural method for diagnosis in questionable cases, and in the control of treatment.

The simplicity of the preparation and use of the culture medium for amebas recommends it to any laboratory. It is prepared as follows: Four whole eggs are broken into a sterile receptacle. Fifty cubic centimeters of sterile Locke's solution [2] is added, and the whole emulsified. The emulsion is then distributed in about 10 cc. portions to suitable test tubes, inclined and heated to about 70 C. until solidified. They are then sterilized in the autoclave for twenty minutes at 15 pounds pressure. To this solid medium is now added the liquid component, so that a layer of the liquid covers a whole or part of the slant. The liquid component is sterile, inactivated human or horse serum diluted seven times its volume with sterile Locke's solution. The medium is inoculated by rubbing up against the wall of the tube a selected sample about the size of a pea. The medium should have been previously warmed to body temperature and sterility insured by incubating several days prior to its use. The culture is examined by taking a drop of fluid from the bottom of the tube with a capillary pipet.

The differential diagnosis of the amebas encountered in culture is beyond the scope of this note; however, after long study I have reached the conclusion that the movement and form taken in movements are sufficiently characteristic of the large strains of *E. histolytica* to aid materially in its identification. The rate of movement in culture, calculated from that of four active specimens, is 27.9 microns to the minute, or slightly less than 1½ inches a day. The form assumed while in motion is that spoken of as "band form"; that is, the long diameter is two or more times that of the transverse. So characteristic is the movement of *E. histolytica* that any entozoic ameba obtained from man in culture which is found to move actively across the field of the microscope should at once incite a strong suspicion that the ameba in question is *E. histolytica.*

The culture medium also contributes materially to the assets of the systematic student of the amebas of man and to the epidemiologist. To the investigator, a way is opened for more extensive research into the biology of the organisms than has been possible in the past. To the epidemiologist, an effective instrument is offered for the detection of carriers of *E. histolytica* and thus indirectly assistance in the control of the spread of the disease. It is probable that the application of the cultural method to surveys of the population will necessitate a revision upward of the incidence of amebas in man.

The field of the cultural method for the detection of amebas, therefore, is wide, and it is confidently expected that, through the use of this medium, a wealth of discoveries will be forthcoming in the very near future. Undoubtedly, this discovery of Boeck and Drbohlav marks another milestone in the history and conquest of amebic dysentery and is worthy of a place along the path blazed by Lösch, Koch and Kartulis, Schaudinn, Councilman and Lefleur, Craig, Vedder and Walker and Sellards.

ERROR OF BASING SERUM DIAGNOSIS OF SYPHILIS ON THE KAHN REACTION ALONE *

SIGMUND S. GREENBAUM, M.D.
Associate Professor of Dermatology and Syphilology, Graduate School of Medicine of the University of Pennsylvania
PHILADELPHIA

It is so well known and generally recognized that the Wassermann test may at times yield a falsely negative reaction in syphilis that it is not my purpose here to discuss the subject except to state that improvements in technic have reduced their occurrence to a minimum, this being especially true of the Kolmer complement-fixation test. But the question of falsely positive reactions has been discussed at even greater length, so that the impression generally prevails that the occurrence of falsely positive Wassermann reactions is even more common than falsely negative reactions. This is certainly not true of the Kolmer complement-fixation test, as experience has shown conclusively its specificity for syphilis, as indicated by the recent review of Kilduffe.[1] The Kolmer test has been used in this clinic for about four years, and in no instance can falsely positive reactions be said to have occurred. But the Kolmer test may occasionally yield a falsely negative reaction, as is true of all complement fixation tests for syphilis, although in my experience it is the most sensitive complement-fixation test evolved for the serum diagnosis of syphilis, which preserves intact the more important factor of specificity. It is to be understood, however, that these remarks are based on tests conducted by the quantitative method of Kolmer and not by modifications of his technic or the use of his new antigen in other methods. The only modification introduced by him since the method was published in 1922 is the routine removal of natural antisheep hemolysin, which has still further increased the sensitiveness of the reactions. Many, but not all, of the reactions reported on in this communication were conducted with this improvement in technic.

Just as there have been numerous modifications of the Wassermann test in the last twenty years, many different serum precipitation tests for syphilis have been proposed since Michaelis[2] discovered the phenomenon in 1907. During the last five years, interest has been greatly increased by Sachs, Georgi and Meinicke in Germany, Dryer and Ward in England, Vernes in France and Kahn in the United States. In this country, the Kahn test has commanded most attention; in a series of comparative tests in Kolmer's laboratory by Dr. Max Strumia,[3] it was found one of the most satisfactory. Since then, Kolmer has had the Kahn precipitation test conducted as a routine with all specimens submitted to his laboratory from the clinic of Dr. Schamberg and other services in the Polyclinic Hospital, believing that the serum diagnosis of syphilis was best served by conducting both tests with each serum.

* From the clinic of dermatology-syphilology of Dr. Jay F. Schamberg, Polyclinic Hospital, Graduate School of Medicine of the University of Pennsylvania.

[1] Kilduffe, R. A.: Kolmer Modifications of Wassermann Reactions, Arch. Dermat. & Syph. 6: 709 (Dec.) 1922.

[2] Michaelis: Berl. klin. Wchnschr. 44: 1477, 1907.

[3] Strumia, M. M.: Study of Serum Flocculation Reactions in Syphilis, Arch. Dermat. & Syph. 8: 50 (July) 1922.

This is based on the observation that, with about 4 per cent of serums, the Kolmer reaction may be positive when the Kahn is negative or the Kolmer negative when the Kahn is positive. A number of instances of this kind have already been reported by Kelly[4] from Schamberg's clinic and Kolmer's laboratory; but since then numerous additional and similar reactions have been observed, which it is my special purpose to discuss in this paper, in order to express a note of warning against the use of the Kahn or any other precipitation test alone in the serum diagnosis of syphilis or as a serologic guide in treatment. My purpose, however, is likewise to state that the same is true of the Kolmer or any other complement-fixation test and to express the opinion that the serum diagnosis of syphilis is best served by using both tests as a routine as has been Kolmer's practice during the past year.

I have previously expressed the opinion that the Kolmer complement-fixation reaction has been found specific for syphilis in our experience, and the Kahn test has likewise shown a high degree of specificity, although weakly positive reactions are occasionally reported with the serums of individuals regarded clinically as nonsyphilitic. This is especially true when the reactions are read after the serums stand over night in a refrigerator, and I advise that reactions of this kind be regarded with some reservation in the absence of a history or clinical evidences of syphilis.

In table 1, I have briefly summarized cases regarded as syphilitic in Schamberg's clinic yielding positive Kolmer and negative Kahn reactions. In table 2 are shown an equal number in which the Kolmer reaction was reported negative and the Kahn positive. They have been listed as observed and without selection as reported to the clinic during the past year, and constitute about 3 to 4 per cent of discrepancies between the two tests. In other words, both tests agreed as far as positive or negative were concerned in from 96 to 97 per cent of the cases; but the fact that, in any particular case, either one of the tests may yield a falsely negative reaction constitutes, in my opinion, an important practical reason for conducting the serum diagnosis of syphilis by both instead of by either one alone.

Instances of discrepancies of this kind occurred in all clinical types of syphilis, although in my experience the larger number are instances of negative Kolmer and positive Kahn reactions in treated cases of syphilis. When treatment is guided by the Kolmer reaction, far more is required to produce a state of negativity than with the original Wassermann test or most of its modifications; but not infrequently the Kahn test continues to yield positive reactions even after the Kolmer reactions are negative. Whether this indicates continued infection with *Spirochaeta pallida* or merely the longer persistence of antibody in the blood cannot be stated at present, although in a number of such instances spinal fluid studies still showed a positive Kolmer reaction.

Of course it is frequently observed that the two reactions vary in the degree of positiveness, but it is impossible to compare them accurately on this basis, because they vary so greatly in technic and the immunologic principles involved. Nor is this a matter of much clinical

importance; and it is of infinitely less importance than the question of a true and specific positive or negative reaction regardless of the degree of positiveness.

I hope, however, that the instances listed in the tables will serve to indicate the mistake of using the Kahn test alone for the serum diagnosis of syphilis. I believe it is particularly necessary to publish data of this kind at present, in view of the fact that some may be induced to use the Kahn or other precipitation test alone in the serum diagnosis of syphilis. It is true that under acceptable conditions the two tests agree so far as positive or negative reactions are concerned, but in the best interests of the serum diagnosis of syphilis both the Kolmer and the Kahn tests should be employed.

MODIFICATION OF PRESENT METHODS OF GASTRODUODENOSTOMY *

WALTER HUGHSON, M D.
BALTIMORE

The increasing interest in pyloric resection and its growing importance as a method of treating ulcerations of the stomach and duodenum are matters of common knowledge. Furthermore, there is the mounting conviction that in suitable cases some form of pyloroplasty or gastroduodenostomy is the operation of choice. Unfortunately, until quite recently the choice of operations of this type was comparatively small. The Billroth I operation, the Finney pyloroplasty and the physiologic pyloroplasty of Horsley for many years offered the only satisfactory surgical means of restoring the normal physiologic relations of the stomach after resection of an ulcer at the pylorus or in the duodenum. The Billroth I operation fell into a rather undeserved disrepute, and in the latter two operations ordinarily half the pyloric ring remained intact, which may possibly be a disadvantage, for certain it is that there is a marked delay in emptying in many cases following pyloroplasty.

In 1923, Finney [1] reported an operation for gastroduodenostomy independently of von Haberer,[2] whose paper had appeared the previous year (fig. 1 *a*). In this operation the end of the stomach was sutured to the side of the dodenum after the end of the duodenum had been inverted. This operation marks a distinct advance in surgery at the pylorus and of course adds to the available methods. Horsley [3] reports an interesting modification of the Billroth I operation, which he has practiced with satisfaction for some time. This procedure involved splitting the duodenum in the long axis for a short distance and flaring out the end to avoid occlusion of the lumen by the circular sutures of the original operation (fig. 1 *b*).

The method here described is offered only as a modification of the Finney-Haberer operation and in no sense as a new procedure.[4] Inversion of the duodenal stump is always a source of some concern, and inversion with subsequent reopening, as in the Finney-Haberer operation, does not seem necessary in all cases. This inversion uses up at least 2.5 cm. of the available duodenal length, and where mobilization is so important—a fact repeatedly emphasized by Finney—

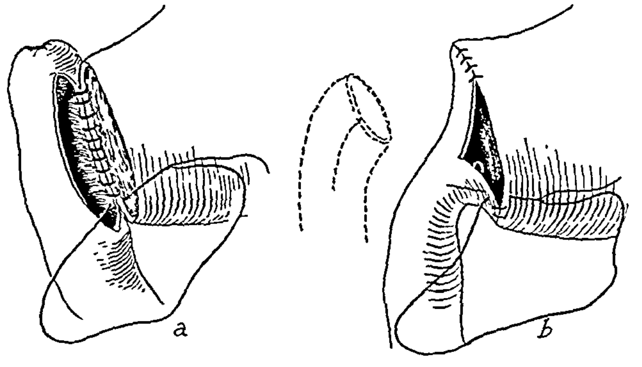

Fig 1 —*a*, Finney gastroduodenostomy, showing inverted end of duodenum impinging on new stoma; *b*, Horsley's modification of Billroth I operation.

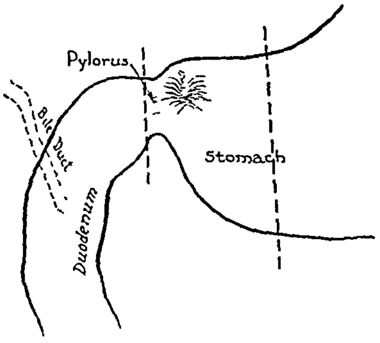

Fig 2 —Ulcer on gastric side of pylorus and area to be resected

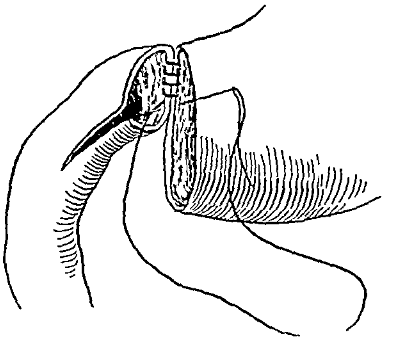

Fig 3 —Beginning suture of duodenum to posterior wall of stomach at lesser curvature and longitudinal incision started

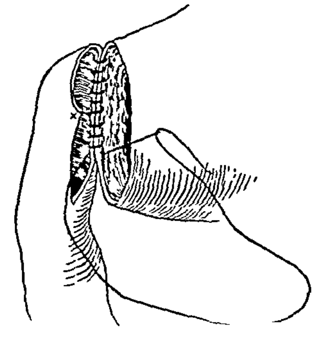

Fig 4 —Posterior row almost completed, *x*, small tab of duodenum, which is trimmed off before suturing

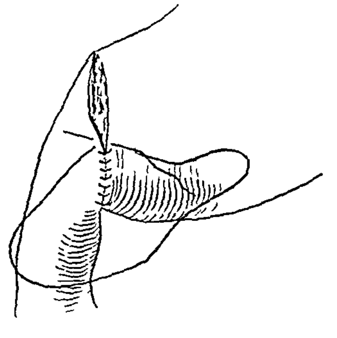

Fig 5 —Anterior wall being closed: general relations and appearance at end of operation

this distance can sometimes ill be spared. In addition, the inverted duodenal stump may become edematous and partially obstruct the available lumen—this fact has been noticed frequently in dogs. It seemed advisable, therefore, to preserve the entire length of available duodenum for suture, and figures 2, 3, 4 and 5 illustrate the method evolved. This procedure was carried out repeatedly on animals two years ago. Starting at the lesser curvature, the end of the duodenum is sutured to the stomach by any method the operator may prefer. When half of the circumference has been used in this way the duodenum is split in its long axis about 1 cm. from its attachment, for a distance sufficient to make the opening correspond exactly to that of the stomach. The small angular tab shown in figure 4 is trimmed off. The posterior suture being completed, the anterior wall is closed in the usual manner. The blood supply is not interfered with in any way and is entirely adequate.

[4] Babcock reports splitting the inner side of the duodenum with combined end to end and side to side anastomosis of duodenum to stomach, and gives a diagram (Am J. Obst & Gynec **9**: 473 [April] 1925).

Opportunity has presented itself to use this method in only one clinical case, but the patient's postoperative course was so perfectly smooth that a brief report seemed justified. At operation the patient presented a perforating ulcer on the lesser curvature about 2 cm from the pylorus. The duodenum could be mobilized readily. The pylorus and pyloric antrum were resected and the technic described above was carried out with a minimum of difficulty.

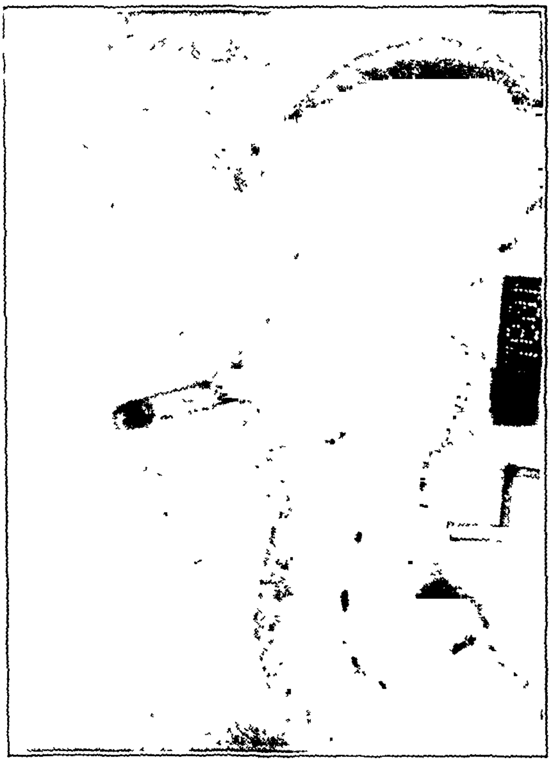

Fig 6.—Rapid emptying one week after operation in case treated by modified gastroduodenostomy.

The patient's postoperative course was quite uneventful. There was no vomiting, no elevation of temperature, and no evidence whatever of retention. A roentgen-ray examination one week after operation showed a perfectly normal emptying time—less than five hours. Figure 6 shows the result of this immediate examination. Gastric analysis done at the same time showed a marked reduction in free acid and practically no regurgitation of bile.

Figure 7 shows the result in a patient on whom a Finney-Haberer operation had been performed. The emptying time here too was normal.

CONCLUSION

The modification of the Finney-Haberer gastroduodenostomy here described offers further choice of procedures for restoring the normal physiologic relations of the stomach after operations that have involved resection of the pylorus.

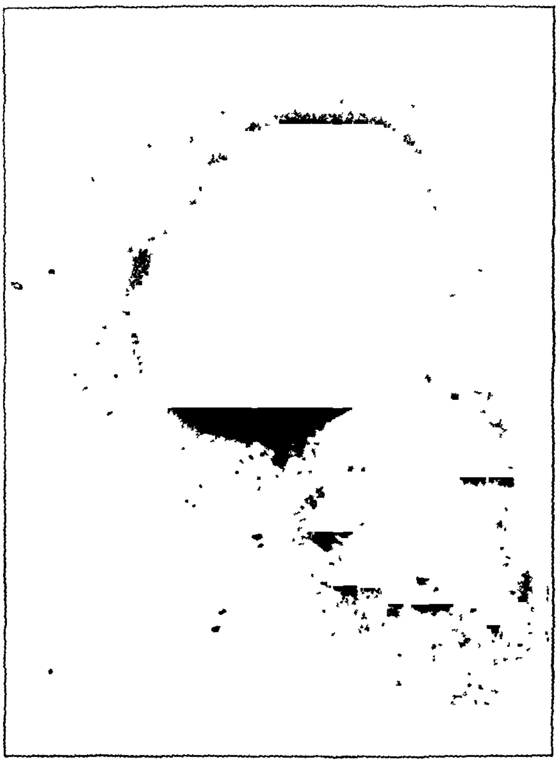

Fig 7.—Examination made two weeks after operation in case treated by Finney-Haberer gastroduodenostomy.

Disease as Regarded by Ancients.—If we look back to ancient medicine we find everywhere the same essential picture, disease regarded as the work of demons or of magic, and a corresponding treatment by the aid of incantations, charms, and exorcisms. Side by side with these demonological conceptions and therapies, however, there existed a certain number of simple surgical practices, and a herbal lore in which, among masses of extraordinary and revolting ingredients, one finds the names of drugs of undoubted efficacy, and value. The Ebers papyrus (1550 B. C.) for example, describes the incantations used in Egyptian medicine, but it also contains a list of remedies including such familiar drugs as opium, hyoscyamus, squills and castor oil. The records of Babylonian medicine show a similar demonological view of the causation of disease, and detail the litanies and incantations necessary for its treatment. Diagnosis is closely connected with astrology, and is made by the interpretation of omens. "In the Old Testament disease is an expression of the wrath of God, to be removed by moral reform, prayers and sacrifice." Yet in both these cases there is ample evidence of the use of simple surgical, herbal and hygienic measures, apparently without relation to the supernatural conceptions applied to disease in general. It is, perhaps, legitimate to assume that the former originally developed on a basis of empirical observation essentially identical with that on which the structure was ultimately to be erected.—Hart, Bernard: *Lancet* **1**:586 (March 20) 1926.

A COMPARATIVE METHOD FOR DEMONSTRATION OF NORMAL DEVELOPMENT IN INFANCY

ARNOLD GESELL, M.D.
Professor of Child Hygiene, Director of the Yale Psycho-Clinic, Yale University
NEW HAVEN, CONN.

Is it desirable for medical students to become more systematically familiar with the normal? In connection with the general course in pediatrics, given at the Yale University School of Medicine, I recently had opportunity to test the feasibility of demonstrating to junior students the developmental characteristics of normal infants. The present paper is a stenographic report of one session devoted to the clinical demonstration of two pairs of normal infants, respectively 4 and 6 months, and 6 and 9 months of age.

This session was followed by a clinical demonstration of mental deficiency in infant subjects. It was our purpose, in the comparative examinations, to clarify the nature of developmental retardation by a preliminary presentation of normal characteristics; and also to illustrate the principles of developmental diagnosis.

From the standpoint of developmental diagnosis we are primarily interested in all those forms of behavior, mediated by a nervous system, which are coherently related to the attained maturity of that nervous system. We may conceive such behavior as being a functional index of developmental status. An infant is as old as his behavior.

In this sense the mind becomes an observable object within the scope of developmental diagnosis.

For several years we have been attempting at the Yale Psycho-Clinic to determine behavior norms of infancy, and to define diagnostic procedures which might enable us to make objective estimates of developmental status in early life.[1]

A few of these procedures are illustrated in the comparative examinations described below. The conditions of the examination were simple. Two ordinary, normal infants were brought into the pit of the clinical amphitheater by their mothers. The mothers seated themselves side by side at two small tables, the babies in their laps. The spontaneous behavior of the babies was noted and compared.

While the infants were thus seated facing the student group, psychologic test material was served to them in duplicate. One clinical assistant was assigned to each child, and the test situations were presented simultaneously, in order to bring the behavior reactions of the children into immediate, comparative relief.

The convincingness of the demonstration depended, of course, on the actual behavior of the children, which is only imperfectly suggested by the accompanying illustrations. The comparative situations and the comments made on them were substantially as follows:

NORMAL BEHAVIOR AT FOUR AND SIX MONTHS

The purpose of this demonstration is to show the importance of the comparative method in developmental diagnosis.

A law of contrast apparently controls clinical perception and clinical judgment. It is difficult either to see or to evaluate symptoms of development as isolated phenomena. They take on definition and meaning only when seen in terms of a higher or lower level of development; that is, in comparative terms.

Systematic comparison is a fundamental scientific procedure. It is of especial value in the elusive field of development. We cannot measure development with mathematical precision, but we may descriptively formulate successive levels of development and we may bring these levels into diagnostic comparison. We may do this whether we are concerned with normal or subnormal manifestations.

Naturally, our basis of reference is the normal or median child. Our true norms or standards must be sought in a study of the normal. Next week it will be time to see mentally retarded subjects. Today we shall observe infants who are making normal progress on their developmental journey but who have not covered the same distance. One is two months "ahead" of the other. If you will compare their behavior you will see a discrepancy. That discrepancy is a measure of the difference in their developmental status. Developmental diagnosis deals with just such comparative differences.

Ordinarily the physician diagnoses one individual at a time. Now, however, two are being scrutinized. One is estimated or measured by means of the other.

You see at once the usefulness of the comparative method of approach because without your willing it, I think, your perception is sharpened by the fact that you can bring two infants into simultaneous comparison. You observe a certain control and poise in the senior infant (aged 6 months) compared with the perfectly normal, but wobbling equilibrium of his junior (aged 4 months). This confers a certain aspect of sedateness and poise on the older child which is a valid clinical impression. This more advanced motor control is a behavior difference, correlated, of course, with the greater maturity of the nervous system of the older child.

[Each baby is lifted in turn. And then they are placed side by side on the tables, to show the difference in sitting posture.]

If I hold these babies and just lift them in order to get the tension feel, I detect a difference that is motor in character, as the result of a greater tonicity and reactiveness in the postural control of the older child, who is in fact much farther along in the mastery of the sedentary posture, in which students are quite skilled. This baby, if he is carefully placed, will momentarily maintain a sitting posture. This is scarcely possible with the 4 months old child, and it will be noticed that nature has therefore conferred a little more solicitude on the part of the mother of the 4 months old child, who is a little less ready to release her protective hold. Naturally so, because the baby is not quite so independent as yet. There is a certain nicety in this adjustment of relation between the mother and child which asserts itself all along the growing period, in conformity with the increasing independence of the child as he matures.

[The examiner demonstrates a difference in the rigidity of head posture by placing the baby's head between the palms and gently exerting pressure to right and left, and then forward and backward.]

Now there is another item worthy of inspection under certain diagnostic conditions comparable to the one just referred to; namely, the resistance of the head to lateral pressure and to pressure backward and forward. We have no precise objective measure of this resistance.

---

[1] The norms of development and their diagnostic applications are described by Gesell, Arnold: The Mental Growth of the Preschool Child: A Psychological Outline of Normal Development, Including a System of Developmental Diagnosis, New York, The Macmillan Company, 1925.

However, you see that there is a difference in the fixity and rigidity of the head control in the case of the two children at this level of development; and since the lack of attainment of postural control of the head is an important symptom of mental retardation in early infancy, this item of observation is well worth considering.

[The babies are placed in the dorsal position, and the spontaneous movements are noted. The babies are then placed in the prone position to show the difference in postural response.]

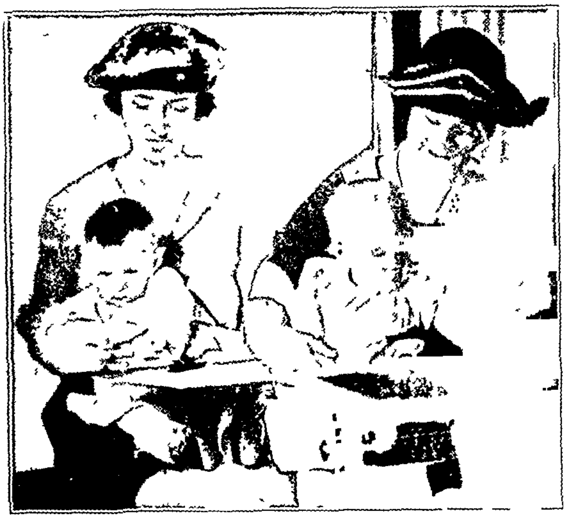

Fig 1.—Normal children, aged 4 and 6 months, side by side for comparison. Tests were simultaneously made to bring out comparative differences in behavior and developmental status.

It will be noted that these babies do not disport themselves in just the same manner while they lie here, in the dorsal position. There are significant differences in the scope and character of the movements of both arms and legs.

The prone position is worth testing in children about whose developmental status one has any doubt, and it will be noticed that at 4 months there is already considerable capacity in the erection of the head. The 6 months child is still farther along; his shoulders are above the table, and one can see the beginning of the creeping posture.

[Each clinical assistant takes a small red ring (4 inches in diameter), suspended from a string, and dangles it before the infant, within easy reach.]

Now something very significant may be witnessed. At 6 months one sees characteristic direct reaching. At 4 months, when the ring is dangled, there is a cruder closing-in reaction in which the coordination is much less under visual control. The directness, the accuracy and the promptness of response are less. This child at 4 months is really somewhat advanced beyond the average level in this reaction. He is just at the brink of reaching, and if by happy chance or by casual contact he touches the ring, the reaction is one which simulates reaching, but which is not true reaching. The difference in the perfection between these two responses is very significant from a normative point of view.

[Each infant is now held in a sitting position and brought slowly toward the table until his hands are within favorable range of the edge of the table, or just touch the table surface.]

Perhaps you are waiting for me to perform a test. Well, this is the test. The question is, How do these two babies react to the table surface? A marked behavior difference may be noticed here. The 6 months old child is aggressive. He playfully exploits the table surface and the table edge. The hands of the 4 months old child are rather idle in this situation. You may say he is inhibited by your presence. I think not. I think his failure to exploit the table is due to his immaturity. His neuromuscular mechanism has not advanced to that stage which is characteristic of the 6 months old child, and therefore he gives only casual heed to the table surface. If his hands touch the table they are likely to linger there, which itself has some significance. He may sometimes perform in a way that simulates a patting motion, but his present restricted reactiveness is the characteristic behavior observed under the more normal conditions of the examining room.

[The infants are still seated in their mothers' laps, facing the table A spoon is placed before each infant. The attention of the infants to the spoon is noted. The spoon is then shifted to the edge of the table, and each examiner brushes it from the table, so that the spoon falls to the floor. The reaction of the infants to the disappearance of the spoon is likewise noted.]

Now we are going to test the perceptual reactions of our subjects—the perceptual capacity. You are certain that the 6 months old baby sees that spoon and he is making a reaching response toward it. We also have definite evidence of regard for the spoon on the part of the 4 months old child. We see the regard expressed in the fixation of facial and ocular muscles; but it is a rather transient regard, certainly not the prolonged attention which this 6 months youngster is showing.

We are still dealing with neuromuscular mechanisms, because the whole perceptual process is a motor process as well as a sensory one, and we are also dealing with symptoms of mental adaptation. We have before us an objective difference—a clinical cleavage with respect to attention, when the mental adjustment of the younger infant is compared with that of his more mature senior. Now, it is clinical cleavages like this that we are interested in. We are trying to formulate behavior differences in such a way that they will enable us to record descriptively and analytically developmental status, and thus take the problem of mental growth somewhat out of its present state of elusiveness.

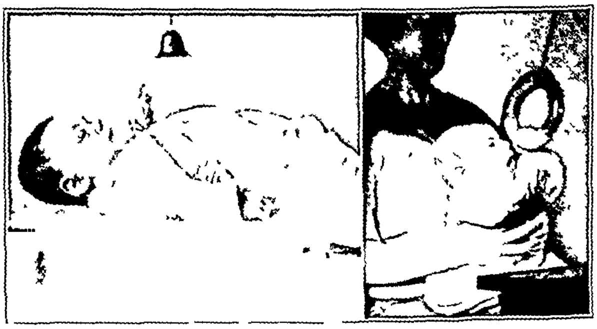

Fig 2.—The 4 months old infant lies down and looks at a stimulating object; the one 6 months old sits up (with support) and reaches for the object

Now please note the difference in behavior, when the spoon suddenly falls to the floor. The 6 months old baby is transiently aware of the disappearance of the spoon; gives heed, so far as we can infer, to its disappearance. The 4 months old baby may also "miss" the spoon, but in a different manner. Neither child pursues a quest for the vanished object.

We must reckon here in some way with the mechanism of attention, because attention has to do with fixation, and surely it has to do with this fundamental quality of projection, or of prolongation of interest which we often call concentration. When we bring in our 9 months old infant we shall doubtless see a projection of interest which can well be considered as a kind of inquisitiveness into the fate of the dropped spoon.

[One by one, several small disks of diminishing size are placed on the table before each child. The first disk is a large wooden button, 4 cm. in diameter; the last in the series is a small pellet, 0.5 cm. in diameter.]

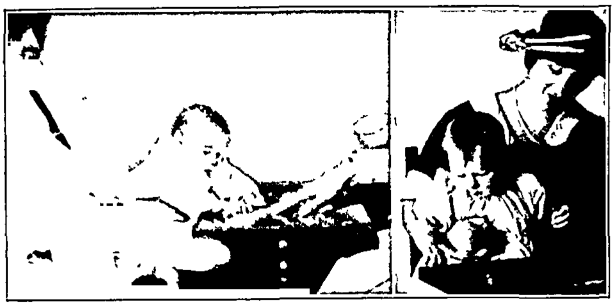

Fig. 3.—Prehension: The 6 months old infant scoops up a small pellet with his palm; the 9 months old infant picks it up with forefinger and thumb.

We come back to the question of perceptual reactions and present a series of disks, graduated in size. This simple test indicates that the size of the stimulus and the age factor influence the perceptual response.

The visual fixation of the 4 months old child is elicited by the larger buttons. A reaching response, as well as visual regard, is aroused in the 6 months old child. The 4 months old child does not pick up any button. The 6 months old child picks up the larger buttons with ease, but as we approach the smaller sizes we get into his difficult zones. The typical 9 months old infant can pick up this smallest pellet with fairly adept prehension. At 6 months we get characteristically a visual regard for the pellet, and not infrequently a palmar scoop reaction which results in a raking in of the pellet. But we are never very much alarmed or surprised if, under favorable conditions, he fails to make a manual approach on this tiny pellet.

[A piece of paper, 8 by 10 inches, is presented to the 4 months old child and pressed into his hands. A similar piece of paper is presented to the 6 months old child. The difference in the playful activity of the babies with the paper is noted.]

The 4 months old child does not reach for the paper even when it is very favorably presented. That is, he does not actively reach for it. At 5 months we have observed that paper favorably placed in this manner will be attained by the child. The 6 months old infant seizes it directly. The 4 months old infant, however, will grasp the paper if it is pressed into his hand. Both children "play" with the paper. But the degree and the quality of manual exploitation of the paper are distinctly superior in the 6 months old infant.

Taken by itself, this observation is not of much importance; but, comparatively interpreted, it is an objective item that may contribute to our diagnostic estimate. The 4 months old infant is apparently below the level of the 6 months old infant both in play interest and in play capacity.

Does your baby play with toys? we ask the mother of the younger child, and she answers, No. Does he play with his hands? Yes. He has just begun to hold them up for playful inspection. In this way he is perfecting the neuron connections which bring eye and hand into coordination for the reaching-on-sight, which becomes so prominent in the behavior picture at the age of 6 months.

We question the mother of the 6 months old child and find that he plays with toys—a rattle and a rubber doll. He has not, however, acquired any domestic tricks, such as waving bye bye. These acquisitions, as symptoms of normal development, come somewhat later, as we shall see. We must not expect too much; but we may say that, from the standpoint of norms or standards, the average 6 months old babe is competent to play with a rattle. Even one such item may have a normative value in constructing an estimate of developmental status.

Summing up, we may say that the behavior of both these babies rates up to the expected level. In actual performance and in the quality of their reactions, both subjects are normal. It has been our purpose to give a clear-cut comparative view of the normal behavior characteristic of two closely adjacent age levels. Only two months separate these children chronologically. If, however, this 6 months old baby today, under our tests, had behaved consistently like our 4 months old baby, we should have to infer a grave degree of retardation. Constitutional retardation expresses itself early. The time clock is an important factor in determining normality of development. Attained development is a true index of prospective development. Within judicious limits, even infants must measure up to certain standards.

NORMAL BEHAVIOR AT SIX AND NINE MONTHS

[A 6 months and a 9 months old infant are next brought in, and observed in the same comparative manner as the previous pair. Their postural control and their spontaneous reactions to the new situation are first noted.]

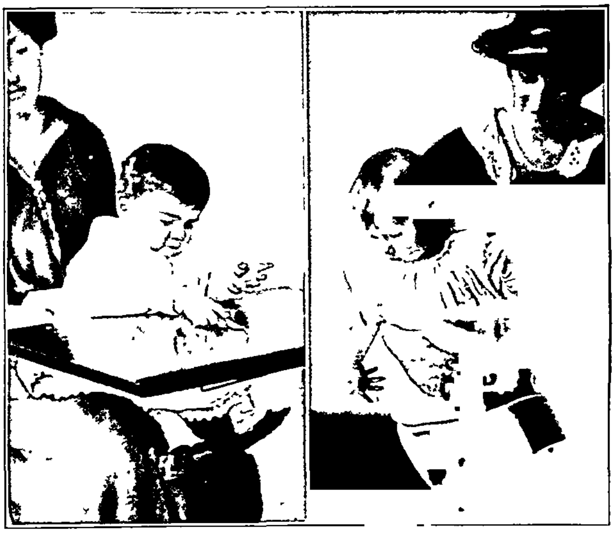

Fig. 4.—Memory and attention: The 6 months old infant shows a transient awareness of the disappearance of a spoon, when it is dropped on the floor; the 9 months old infant shows a definite follow-up interest.

The ages of these infants are, respectively, 6 months and 9 months. We might have used the same 6 months old subject as before for this comparison, but it is just as well to have another representative. We may be pretty sure that his behavior will approximate that of his predecessor.

Three months makes a difference. It will be noted by the behavior of the 9 months old infant as he is brought into the room that we shall have to be duly considerate of his emotions. We are dealing with a more highly socialized individual. By several tokens he has already shown that his social maturity, his personality, is on a perceptibly higher level. The 6 months old child is sensitive to persons, but not to the same degree or to the same extent as the 9 months old child.

Postural control is definitely more advanced in the older child. The mother is holding him much less securely. In fact, he is maintaining a sort of independent position in the lap. His head control is more advanced. This may be noticed when he turns his head, as he frequently does toward his mother, as though seeking assurance. But he is becoming rapidly adjusted to his new situation.

When placed on the table, the 6 months old child cannot sit without support. The 9 months old child can.

On the first comparative examination, it was the 6 months old child who seemed posturally steady, but now the situation has altered. It is the six months old child who seems to lack equilibrium by contrast with the 9 months old. This suggests the significance of comparative and normative procedures in developmental diagnosis.

[The children are seated in their mothers' laps at the tables. A spoon is proffered to each one simultaneously to elicit the reaching and prehension responses. The spontaneous play with the spoon is noted. The spoon is then withdrawn from the child's hands, is placed near the edge of the table and suddenly brushed from the table onto the floor, to determine whether there is any follow-up interest on the part of either child.]

A definite difference will be observed in the reaching response. The 9 months old infant reaches with more directness, particularly overhead. His reaching is also more unilateral in character; right handed differentiation is asserting itself. When the spoon is placed on the table, he picks it up with perceptibly greater skill. He exploits it more elaborately in play, and resists withdrawal of the spoon. He is audibly expressing his "impatience" or his desire to play some more with the spoon. He was quietly content a few minutes ago; but having been keyed up to playing, he wishes to continue. A kind of circular reaction is at work.

We promised you a comparison with the 9 months old infant in the fallen spoon situation. Here you have it. The 6 months old infant betrays merely a dim, fleeting awareness of the sudden disappearance; the 9 months old child shows a follow-up interest by promptly looking down on the floor in quest for the spoon.

[A small pellet (0.5 cm. in diameter) is placed before each infant, to note the character of the prehension.]

This simple but rather interesting test clearly reveals the advance which has been made in the prehensory apparatus; that is, in the concealed part of the apparatus; namely, its neuronic organization. In the 6 months old infant there is still a rather crude scooping reaction by simultaneous flexion of the digits and cupping of the palm. In the 9 months old infant there is a more precise pincer-like prehension, bringing the forefinger and thumb into opposition on the pellet.

[A small wood cube is offered to each infant as before; then a second, and a third.]

You observe that the 9 months old infant holds two cubes with more readiness than his junior partner. He also shows more interest in a third proffered cube. Sometimes the 9 months old child will acquire the third cube, by dropping one in hand, or holding two in one hand, or by a prehensile reach with his mouth. This means, of course, that the scope of attention is widening. In another year this child will take and retain almost as many of these cubes as you can offer him.

[The table is cleared. One of the small cubical blocks, an enamel cup, and later a piece of paper are presented to each infant to elicit spontaneous play behavior.]

You note that the 9 months old child makes a more vigorous playful attack on the table, when only the table surface is the stimulus. He also plays more elaborately with the block and the cup. He shoves the cup back and forth or brings it up to his mouth, or bangs the block against the cup. At the age of 1 year he may repeatedly place the block into the cup in his experimental activities, but this is quite beyond his powers now.

The range and general character of the playful exploitation of the sheet of paper indicate the greater psychologic maturity of the 9 months level, compared with the 6 months level.

One can also detect a greater social maturity in his responsiveness to your presence and to your laughter. You may describe this as greater interest in the social environment. This interest shows itself in numerous ways in his domestic life. He is more communicative than his junior; he is more sensitive to communication; he has assimilated more from his personal surroundings. We ask the mother, "Does he say anything?" "Yes, mama and dada." "Does he wave bye bye?" "Oh, yes!" "Has he learned any tricks?" "Yes, he can put a handkerchief over his head, when you tell him."

Behavior items like these are good indicators of what is going on in the growth of the child's nervous system. Not only do they suggest an increase of intelligence but a development of the countless social habituations, emotional trends and attitudes which steadily build up what we psychologically designate as "personality." Mental growth is permeated with conditioning factors. It is interesting to note that this particular 9 months old child is at present so conditioned that he will wave bye bye to his father, but to no one else.

The differences we note in the behavior of this pair of infants are therefore differences not only of intelligence but also of personality make-up. This comparative view may serve to remind us that there are arrests, retardations and deviations in the sphere of personality development as well as in the development of intelligence.

The comparative or normative approach, therefore, is essential to the task of developmental diagnosis. We cannot evaluate behavior altogether on its own merits but only on its comparative merits, with scrupulous regard for the age factor. Both of these children have made relatively normal developmental progress; but reverse the behavior pictures, so that the senior member of the pair reacts like the junior member, and there is a syndrome that may justify a diagnosis of mental subnormality.

COMMENT

The pediatrician, accordingly, must take a critical interest in norms of development. Such norms are the objective standards for deriving a clinical judgment in all situations requiring a diagnosis of developmental status.

Development, as well as disease, falls within the scope of medicine. Development may be studied from purely anatomic and physiologic points of view. But it may also be studied through the functional index of behavior. By the comparative method, we have tried to demonstrate that this index is a lawful one and therefore clinically significant. We have also, perhaps, suggested one way in which a study of the normal may be incorporated into medical instruction.

Clinical Notes, Suggestions, and New Instruments

AUTOTRANSPLANTATION OF A TOE FOR TRAUMATIC LOSS OF A FINGER

JOSEPH E. FULD, M.D., NEW YORK

Nicoladoni[1] was the first to describe the autoplastic transplantation of a toe for the traumatic loss of a finger. He successfully performed and described an operation in which he replaced a thumb by transplanting the second toe. Since then very few cases of successful transplantation of toes to replace lost fingers have been reported.

Fig 1.—Amputated finger.

REPORT OF CASE

G. S., a man, aged 30, while operating a bread-slicing machine, Sept. 18, 1925, accidentally amputated the distal third of the middle finger of his right hand. The wound being recent and clean, I considered this a favorable opportunity to attempt grafting a toe to replace the missing finger. The day following the injury, the patient was placed under ether, and after exceptional care of the surgical field, I made an incision at the level of the head of the fifth metatarsal bone, transversely across the dorsum of the small toe of the right foot, deepened through, exposing the extensor tendon. This was cut across and the bone disarticulated. The incision was carried farther until the toe was left attached to the foot by only a pedicle plantar flap, consisting of skin subcutaneous tissue, plantar vessels and flexor tendon. The dorsal skin edge of the stump of the finger was freshened. The end of the extensor tendon was sutured to the distal end of the extensor tendon of the toe, and the dorsal skin edge of the finger was sutured to the distal dorsal skin edge of the toe. This necessitated complete immobilization of the parts with the hand in constant juxtaposition with the foot. Plaster of Paris was not used, it being found that complete immobilization could be made by properly placed adhesive plaster and gauze bandages. The patient was placed in a Gatch bed, which permitted flexion of the body to almost an upright sitting position. This gave a fairly comfortable position and relieved tension on the bandages. I am of the opinion that at least two weeks is necessary, with constant attention and frequent dressings, for a union to take place.

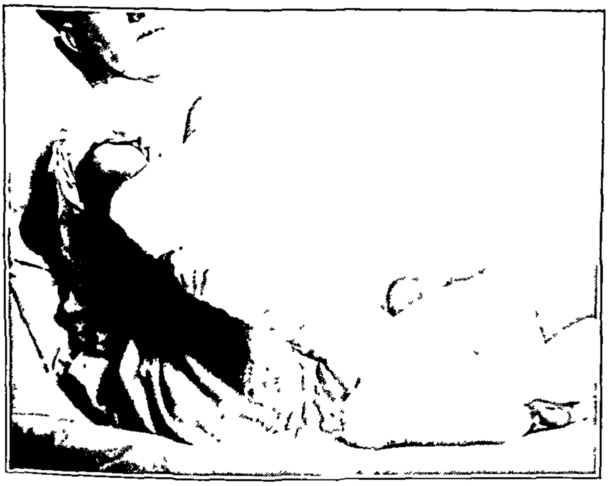

Fig. 2—Position of patient in bed, with hand and foot approximated.

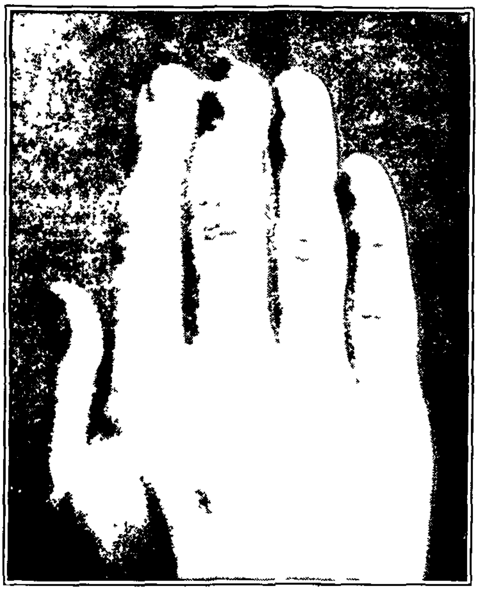

Fig 3—Appearance of hand two and one half months after transplantation of toe. The transplanted toe was long enough to extend as far as the tips of the index and fourth fingers.

The second stage of the operation was performed as follows: The pedicle flap was cut across transversely, exposing the flexor tendon, which was also cut and sutured to the flexor tendon of the finger. The skin wound was closed with interrupted sutures. Passive motion, confined to flexion, was instituted on the third day after the second stage of the operation. No hyperextension was necessary or used. The cosmetic result was satisfactory, and sufficient function was obtained to permit the closing of the hand in complete flexion. Sensibility has partially returned. The color of the skin is practically the same as the color of the other fingers.

COMMENT

The value of the operation does not consist alone in giving a more sightly hand, but in restoring the normal length of the finger. It gives to those whose occupation requires exceptional use of the fingers an opportunity to continue their work. Musicians, pianists, violinists, typists and penmen will appreciate a functionally complete member. Laborers whose chief finger is the thumb will regain the grasping power that is necessary to continue their wage earning ability.

Nicoladoni advocates two methods. The first consists in a plastic cuff from the chest, into which a graft from the tibia is transferred. This permits of abduction and adduction only, whereas in the second method a transplant of the toe carries with it the extensor and flexor tendons, which offer not only abduction and adduction, but also flexion of the new thumb, which restores in great part the grasping ability of the hand

Close application to details is essential to provide a good healthy plantar pedicle flap and the preservation of as many blood vessels as possible, the proper suturing of tendons, strict asepsis, and a careful watch to guard against hematoma, which is almost certain to become infected and destroy an otherwise perfect result. If these precautions are observed, a useful member may be added to the hand at the expense of a seemingly unnecessary toe.

MODIFICATION OF TURNBUCKLE JOINT FOR TREATMENT OF SCOLIOSIS: SUGGESTION AS TO MANAGEMENT[*]

Charles N. Pease, M.D., Chicago
Assistant Attending Orthopedic Surgeon, Home for Destitute Crippled Children

In 1924, Lovett and Brewster[1] published a series of articles on the treatment of scoliosis with a turnbuckle jacket. Briefly, their principle is the application of pressure on the curved part of the spine and counterpressure on the spine above and below the apex, thus correcting lateralization and, at the same time, rotation of the spinal column. This is obtained by a jacket made from a corrected plaster torso of the patient. It is divided transversely at the level of the apex of the lateral curve, at which point a hinge is fastened. Opposite this is placed the turnbuckle and lock, which are used to separate the segments and to hold them in position, respectively.

The correction obtained with this type of jacket is exceptionally good. The question is whether or not the new position can be maintained after its removal. It cannot, unless the musculature of the trunk is developed sufficiently. It is well known that plaster jackets applied to scoliotic patients cause a marked atrophy of the thoracic and abdominal muscles, sometimes to such a degree that if the patient is allowed to stand unsupported after his jacket is removed, he goes into collapse.

In order to maintain the muscular development the patient already has and to strive to increase it if possible, he must be exercised several times a day. Many short periods of exercise are better than one or two exercise periods of long duration. This is because, in the latter case, muscle fatigue occurs, which is worse than no exercise at all. Exercising below the limit of fatigue is efficacious in the development of musculature. The present jacket cannot be removed several times a day, which is desired, because it becomes weak and is easily broken.

Therefore, I have taken the turnbuckle jacket and have divided it in the midline of the back and fastened it together with hinges. This does not alter the strength or stability of the jacket and yet allows it to be removed without breaking. As easy application and removal are thus facilitated, the patient may exercise several times a day and, during the intervals, be held in a corrected position. This, I believe, may aid greatly in solving a most important problem in the treatment of scoliosis.

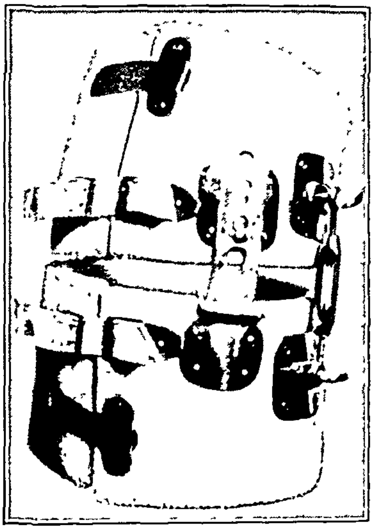

Fig. 1.—Front view of jacket, showing turnbuckle and lock.

Covering the jacket with stockinet before application of the metal parts is a suggestion received by the department of nursing at the Home for Destitute Crippled Children.

When this paper was presented for discussion, Dr. John Ridlon called attention to the fact that the divided jacket was not new, it having been used fifty years ago. Milton Josiah Roberts[2] first used it in the treatment of Pott's disease, and due credit should be given him. However, it may be stated that Lovett and Brewster used it in a different manner and were the first to use it in the treatment of scoliosis.

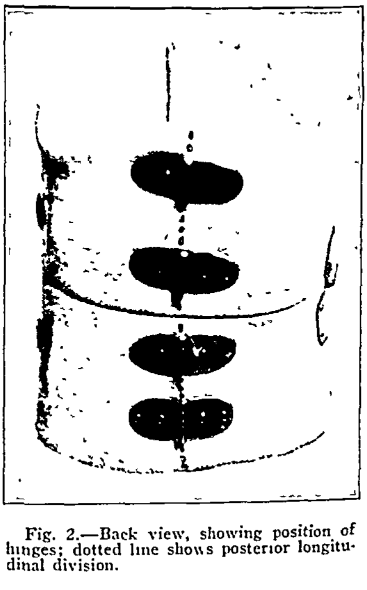

Fig. 2.—Back view, showing position of hinges; dotted line shows posterior longitudinal division.

104 South Michigan Avenue.

The Athenian State Little Concerned with Education.—The school age for the boy (in Athens) began with his seventh year. Custom required that each son of a free citizen should be given instruction in gymnastics and music; but, beyond keeping an eye on the morals of teachers and the conduct of their charges, the state did not concern itself with education. It rested with the parent alone to decide how much schooling his boy should receive, and the schools were in all cases private institutions, supported by the fees of pupils.—Leonard: History of Physical Education, p. 20.

SOME NEW ASPIRATING DEVICES

L. K. Ferguson, M.D., Philadelphia
Agnew Fellow in Surgery, University of Pennsylvania School of Medicine

In an effort to increase the neatness and dispatch of an operation, to reduce infection, and to minimize the trauma and manipulation, especially in operations under local anesthesia, these aspirating devices were made. They have proved so useful that I feel justified in publishing a description of them.

The aspirator is not a new apparatus in the surgical clinic, but its application is daily becoming more general and its use, once one becomes accustomed to it, is nearly indispensable. By its use, fluids in the wound or in a cavity may be quickly removed from the field, thus keeping the operating table neat and tidy. Since the aspirator can be used in a wound to remove obscuring fluids while the operator proceeds with his manipulations, nearly obviating the necessity for sponging, the speed of an operator can be materially increased. By removing pus from cavities without spilling, a large amount of wound contamination is avoided, and healing is much more rapid. In much of the work under local anesthesia, the trauma of sponging, however slight, is painful. This element can largely be eliminated by the substitution of an aspirator for a sponge.

The aspirators shown herewith have one point in common, which is absent from most aspirators in use today. Heretofore, one was frequently afraid to insert an aspirator into a cavity, especially the abdomen, for fear some delicate body, frequently the omentum, would be sucked into the fenestra, and its removal would necessitate removal of the tip or the cutting off of the aspirated part. We have been able to overcome this tendency by the insertion on our aspirators of an air valve which can be closed or opened by the operator's thumb. This valve was originally devised by Dr. Gabriel Tucker for use on the aspirators used in Dr. Jackson's clinic. When the thumb is removed from the valve, the suction at the tip is relieved. The tips are all made with an angle so that, when the aspirator is inserted into a wound, the user's hand does not obscure the field. This feature has also allowed us to substitute them for retractors in some positions, allowing the aspirator tip to keep the field dry and also to keep obstructing tissues out of the operative site.

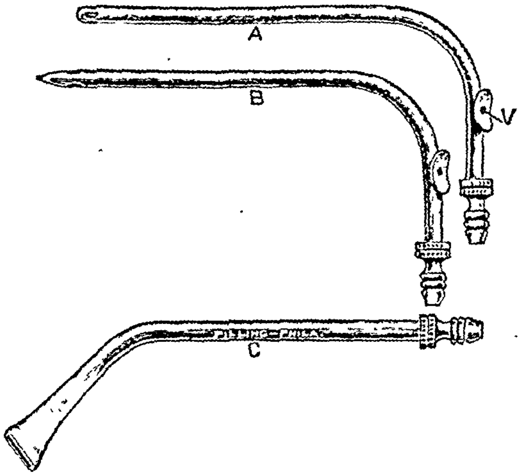

Fig. 1.—Aspirating tips.

The tips that I have devised are of various shapes made to meet various requirements. The aspirating trocar (fig. 1 *B*) is made with a sharp, round point, with fenestra close to the point. It was intended for use in fluid-containing cavities, to evacuate the cavities rapidly without spilling their contents into the operative field. The round point makes a hole in the containing wall which closely fits the aspirator tube, and with a good negative pressure in the suction circuit, no leakage occurs. As the cavity walls collapse, they may be grasped by Allis forceps and the sharp pointed tip substituted for the blunt pointed one (fig. 1 *A*) by means of which practically all the fluid can be removed.

We have employed these two tips in the aspiration of gallbladders, ovarian cysts, empyemas, liver abscesses, breast abscesses, enterostomies for intestinal obstruction, and, in short, in virtually every condition in which a fluid-containing cavity had to be opened. Depending on the size of the cavity, some time is necessary to evacuate the fluid, but this time is much less than that necessary to sponge out the wound when the fluid spills into it.

The tip illustrated in figure 1 *C* is one originally devised for aspirating in perineal operations in gynecology and obstetrics, but it has been found useful in keeping abdominal and other wounds dry. It has a broad, flat tip which allows for a rapid removal of fluids on a comparatively flat surface.

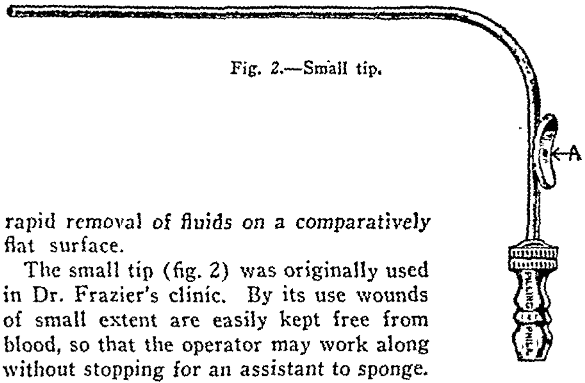

Fig. 2.—Small tip.

The small tip (fig. 2) was originally used in Dr. Frazier's clinic. By its use wounds of small extent are easily kept free from blood, so that the operator may work along without stopping for an assistant to sponge. It has proved most useful in any situation in which careful dissection is necessary, in choledochotomies and other small field work.

These tips have been adopted for daily use in the obstetric clinic of Dr. B. C. Hirst and in the gynecologic clinic of Dr. John G. Clark. In each of these clinics and in our own, a simple water pump is used to obtain the necessary suction, which is connected to a 4 liter reservoir. The water suction is cheap and noiseless, and it never gets out of order.

The nurses in our clinics are most enthusiastic over our use of the aspirators, because, by their use, considerable of their thankless labor of making sponges is reduced. The supervisor of Dr. Hirst's clinic tells me that since the use of the aspirator, the sponges in a cesarean section have been reduced from about seventy-five to thirty-five. Such a saving is an economy which is of some moment in a busy clinic.

These aspirating tips are made by the George P. Pilling & Sons Company of Philadelphia.

326 South Nineteenth Street.

A PECULIAR CASE OF TRANSMISSION OF SCARLATINA

Dean P. Crowell, M.D., Albany, Ore.

B., a boy aged 16, slept in the same bed with his brother, C., aged 14, who had scarlet fever. B., therefore, was in constant contact with his brother for two nights preceding the appearance of a typical rash, and during the usual onset with severe sore throat and high temperature. On diagnosis, the morning of the third day, B. was kept out of his sick brother's room, but remained in the same house. Eleven days after the appearance of the rash, C. left his room and associated with the family and with B. The same day an uncle, aged 35, visited in the home. Ten days after this, B. and the uncle both developed sore throat and three days later the typical rash of scarlet fever.

It seems probable that B., after being thoroughly exposed during the first three days of his brother's infection with scarlet fever, did not take the disease, but eleven days later contracted it at the same time as his uncle and then, after an incubation period of ten days, developed a typical case of scarlet fever. General symptoms were mild in all three cases, and antitoxin was not available. No other scarlatina was present in the rural district in which the cases occurred. The diagnosis of scarlet fever was not doubtful and, within thirty days, a well developed epidemic was in progress in the county.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS*

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(*Continued from page 1213*)

PERORAL ADMINISTRATION OF LIQUIDS IN GENERAL

Solid dosage forms are, as a general rule, preferable to liquid dosage not only because solids are more easily disguised but also because, in prescribing solutions, we must pay especial attention to the solubility, incompatibility, palatability, and the keeping quality of drugs. Liquid dosage is indispensable: (1) for liquid medicines the dose of which is more than a few drops; (2) for deliquescent and liquefying bodies; (3) for irritant substances, including all highly soluble substances given in fairly large doses, though some of these, especially if the dose is quite large or they are not very soluble, are best prescribed in powder form to be dissolved before taking; (4) for ease of variation in dosage—ascending or descending dosage; (5) when the patient cannot well take solid dosage forms, e. g., for children, or (6) because of somewhat greater rapidity of action.

Though all irritant drugs should be given freely diluted with fluid, which means in from a wineglassful to a tumblerful of water or watery liquid, we should, for the sake of economy, aim to make the bulk of medicines in the prescription as small as possible to be diluted before taking: for druggists charge not only in accordance with the expense of the ingredients, but also according to the size of the bottle. so that a patient has to pay considerably more for an 8 ounce bottleful containing the same active ingredients as a 2 ounce bottle. But we must not go to the extreme of preferring drop dosage merely for the sake of economy.

DROP DOSAGE

Drop dosage carries with it some uncertainty, as there is a great variation in the size of the drops, according to the capillarity constant (not the viscosity) of the fluid, the temperature, the fulness of the container. the surface from which it is dropped, and the rapidity of dropping. As drop bottles and medicine droppers vary greatly in size of orifice, the size of their drops differ. The French pharmacopeia specifies a standard medicine dropper that will yield, at a temperature of 15 C., 20 drops per cubic centimeter. With such a dropper, alcoholic fluids yield from 50 to 60 drops per cubic centimeter, according to the alcohol percentage. Ether is so tenuous a fluid that it yields 93 drops per cubic centimeter with the standard medicine dropper. Broadly speaking, drops of strongly alcoholic liquids or of volatile oils are only one-third the size of drops of water, and drops of ether or of chloroform one-fourth or one-fifth the size. On the other hand, so-called viscous fluids may have considerably larger drops than water.

Another disadvantage of prescribing drop dosage is the difficulty the average person experiences in reliably pouring or counting the desired number of drops. The simplest method is to drop directly from the bottle with its stopper partially inserted, so as to permit air to enter from above as the drops escape from below. It is well to moisten, with the fluid, the lower lip of the bottle before the dropping is started; otherwise, some difficulty is experienced at the beginning. Dropping bottles with ground glass stoppers grooved in such a way as to admit air to the bottle at one point and permit drops to escape at another point in its circumference are a great convenience but somewhat expensive. The prescriber should know that it is practically impossible to drop directly from narrow cylindric vessels, as the so-called homeopathic vials of from 4 to 8 cc. size. In such an instance the patient should be provided with a small pipet (medicine dropper) having a rubber nipple attached, which is also the least expensive and perhaps the most generally useful means of aiding patients in the counting of drop dosage of medicine. A modification of the medicine dropper, which is also usable as a container for the remedial liquid to be used in drop dosage, is obtainable. The tip of this dropper bottle is closed by means of a rubber cap, which is removed when the dropper is to be used. This is a good means of dispensing and using not only drop medication for internal use but most especially eye lotions.

In view of these disadvantages of drop dosage, it is best to prescribe drops only when "ascending dosage" is required—when the dose must be found that will give the best effect by gradual increase in its size. In such a case the variation in the size of the drop is of little importance, as the patient starts with a dose that is certainly less than the one that will ultimately be tolerated, and gradually increases it until he finds that which gives the desired result.

ASCENDING DOSAGE

In prescribing, for instance, solution of potassium arsenite (Fowler's solution) in the treatment of chorea, one may start with 5 drops to be taken three times daily after meals, and increase each dose by 1 drop daily, until the desired effect is obtained or until symptoms of intolerance manifest themselves.

In a similar manner, fluidextract of cascara sagrada may be used in conjunction with coarse diet and increased exercise in the curative treatment of constipation, by having the patient determine by experience on himself exactly the dose needed to secure not less than one and not more than two bowel movements daily. This dose may now be continued for a time—say a week—and then reduced by one-half progressively, perhaps every week, until the dose has become quite small and regularity has been established. The patient may put each dose in gelatin capsules just before taking it.

Tincture of digitalis is also frequently prescribed in drop dosage for auricular fibrillation, though best in descending rather than ascending dosage. To a patient who has not recently had digitalis substances given him and who is in great need of the remedy, as much as 60 drops of the tincture may be administered every four hours for a day or two, the effect being carefully watched; and, as soon as the desired result is obtained or untoward symptoms appear, the dose may be cut in half, soon to be still further reduced in an attempt to find the smallest dose required to maintain the therapeutic action.

---

* This is the seventeenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

Diluted hydrochloric acid is frequently prescribed in ascending dosage for patients suffering from hypochlorhydria, to find the dose that will improve digestion best without producing distress. To protect the teeth, the medicament should be given well diluted and taken by means of a glass tube or a straw.

Solution of potassium iodide (official in the new National Formulary), of such strength that each cubic centimeter represents 1 Gm. of the drug, is frequently prescribed in ascending dosage in the treatment of tertiary syphilis. It is best administered diluted in liberal quantities of milk three times daily, after meals.

Creasote carbonate is efficiently given to patients with chronic bronchitis and profuse expectoration, with or without tuberculous infection, by starting with 5 drops shaken up with milk and each day increasing the dosage by 1 drop up to 15 or more, according to tolerance.

These examples may suffice to show the importance of drop dosage in everyday practice.

Ascending dosage—progressive increase of dosage—is employed not only to determine the amount of medicament most suitable for the case in hand, but also and most especially in the process of immunization, to render the patient less susceptible to the influence of certain poisons. The all important question here is the desirable rate of increase. For rapid increase, as at the beginning of antigen (such as tuberculin, pollen toxin or vaccine) treatment, when beginning with a dose much below the one that produces "reactions," doubling the dose might be permissible until a slight reaction is obtained. As soon as this point is reached, the rate of increase will have to be much more gradual. Indeed, it is often advisable to repeat without increase the dose that produced the reaction, if it was at all severe, and then to increase the dose by a much lower rate.

For the proper grading of the further increase in dosage, especially in immunization, but also for other purposes, the common sequence of figures is unsuitable. If, for example, we were to increase the dose from 1 to 2 and then to 3, and so on, the proportion of increase will be much greater at first, when we double the dose, than later when, let us say, we increase it from 9 to 10, in which case the increase would be only by 10 per cent. To increase dosage by approximately 50 per cent, the following row of figures is convenient and sufficiently correct for practical purposes:

First dose, 0.10; 2d, 0.15; 3d, 0.20; 4th, 0.30; 5th, 0.50; 6th, 0.70.

This series may be continued indefinitely by always starting with the same fractions of a ten times more concentrated solution.

If a 50 per cent increase in dosage is too high a rate, then a suggestion made by Ernst Füld [44] might be used. Füld points out that for an approximately 25 per cent increase the following row of figures might have to be employed:

1.0, 1.29, 1.67, 2.15, 2.78, 3.59, 4.64, 6.00, 7.74, 10.00.

It will be readily seen that, by moving the decimal point, the series can be prolonged indefinitely. However, these quantities are not convenient for weighing or measuring. Hence, Füld suggests that progressive dilutions be made 1 to 8 rather than 1 to 10. From any one of these solutions two further dilutions are prepared, the one seven times (designated as solution S) and the other five times (solution F). One part of solution S is used first; then one part of solution F; next, two S, two F; then four S, four F, and next one part of S of the next higher eight times stronger solution, and so forth.

The failure to appreciate the fact that the rate of increase in an immunization process must vary, that a rate suitable at first is unsuitable later, and vice versa, frequently accounts for slow results and even failure. If the lower rate of increase necessary later is employed from the first, time is wasted and the appearance of appreciable results delayed, which may disgust the patient and lead him to discontinue treatment. If the rapid rate of increase permissible at first is continued too long, the severe reactions cause undue suffering, may even do harm, and may make the patient give up the treatment.

The proper spacing of the injections in immunization treatment is also of importance. As is well known, when an antigen is introduced into the system, it causes at first what is called a "negative phase," during which the resistance of the system to the antigen is lessened. Focal reactions in the form of increased activity of the disease process may occur at this stage. Under favorable circumstances this is followed by an increased resistance, the "positive phase," which reaches a certain height and then diminishes very slowly. If the next injection is given too soon, if it coincides with the negative phase, it will still further lessen the patient's resistance. If the intervals are too long, the process of immunization becomes needlessly drawn out. From five days to a week is probably, in most cases, the proper interval between antigen injections.

DESCENDING DOSAGE

When the desired effect has been obtained, it is often good policy to continue the medicine in gradually decreasing dosage. A simple method of accomplishing this purpose is to order the patient to replace each dose by an equal volume of water. In this manner, the content of the active ingredients per dose diminishes steadily and slowly. The rate of decrease is governed by the size of the bottle. The larger the bottle in proportion to the dose, the slower is the rate of decrease. That under these circumstances the decrease is surprisingly gradual is shown by J. R. Miner,[45] who calculates that if, for example, 40 cc. of solution is prescribed, containing 400 mg. of morphine sulphate, and 1 cc. is given at each dose, and if 1 cc. of water is added to the solution for each cubic centimeter withdrawn, then at the tenth dose the morphine content would be diminished by only one fifth, and even at the twentieth dose by less than two fifths. A stage at which the dose of the drug would be one tenth of the original would occur only at the ninety-second dose of the series. Incidentally, it should be noted that the morphine would never entirely disappear from the bottle. Morphine might be prescribed in this manner for treatment of a habitué by the gradual reduction method. The first dose would be the one to which the patient has been accustomed. Bromide is well prescribed in this manner in the treatment of "night terrors" of infants or children, a teaspoonful being put into the bottle for each teaspoonful taken. Hypnotics might also preferably be prescribed in this way.

(To be continued)

THE ABSORPTION OF LEAD THROUGH THE SKIN

The special advisory committee appointed by the Surgeon General of the United States Public Health Service to determine whether or not there is a public health hazard involved in the manufacture and use of tetra-ethyl lead gasoline has made public its report, which shows that "there are at present no good grounds for prohibiting the use of ethyl gasoline as a motor fuel, provided that its distribution and use are controlled by proper regulations."[1] However helpful this report may be, it assuredly cannot be regarded as the "last word" on the subject. The committee itself clearly recognized this when it advised that with the experience obtained and the exact methods now available, it should be possible to follow closely the outcome of more extended use of this fuel and to determine whether or not it may constitute a menace to the public health after prolonged use or under conditions not now foreseen. The Journal likewise has repeatedly warned physicians[2] of the uncertainty that the situation presents.

Education is the best safeguard when experience does not afford convincing conclusions. The impression most prevalent at present with respect to the development of lead poisoning is that the toxic agent finds access to the organism primarily through inhalation of dust and fumes. Interest has thus been centered in the respiratory and alimentary tracts, and prophylactic measures have been directed to these possible channels of entry of the poisonous element. The study of the behavior of "tetra-ethyl lead" and "ethyl" gasoline, such as has recently been reported by Flinn[3] of Columbia University, directs attention to the possibilities of absorption through the sound skin, in addition to the introduction of lead through ingestion and inhalation. So far as application of ethyl gasoline to the skin of animals is concerned, entrance of lead may be secured. The storage of the element may even exceed its elimination for the time being. Flinn insists that this is entirely in agreement with medical experience. Thus far, cases of lead poisoning have not been found at filling stations or garages. Flinn remarks that the time between the man's exposures may be long enough to permit him to remain in apparent good health though he may be storing lead. It may take years before he stores enough or before a sufficient change takes place in his metabolism to cause the symptoms commonly attributed to lead poisoning. The fact to bear in mind, Flinn adds, is that there is no doubt that a storage of lead takes place under exposure.

Lead stored in the body constitutes a potential lead poisoning. These comments are not intended to controvert the conclusions of the committee. They should serve for the present merely to reemphasize an underappreciated avenue for the entrance of lead into the body.

THE HOOKWORM CARRIER

Infestation with hookworm is by no means always of equal intensity among the thousands of persons who harbor the parasite. Theoretically, every hookworm in the intestine may be producing a pathologic condition. Those who deal with the persons affected realize, however, that a large number of the persons whose feces contain hookworm ova are apparently well and strong. If the few hookworms harbored are causing harm, it is not apparent. Cogent evidence of this has further been supplied by actual measurements of groups of children from villages and rural districts in areas of hookworm infestation. Smillie and Augustine,[1] who undertook the latest study of the effect of varying intensities of the infection on the physical condition of school children, argue that if any measurable injury is done by the parasites it should definitely affect the physical development of the growing child. If light infestations are found to have little or no effect on the normal growth and development of a child, then it seems fair to assume that they would have no greater deleterious effect on adults.

The records of Smillie and Augustine refer solely to *Necator americanus,* the species that occurs in our Southern states. They indicate, as might have been anticipated, that heavy hookworm infestation (with 500 or more worms) causes marked retardation in the normal growth in height and weight and lowers the hemoglobin of children of school age. An intensity of from 100 to 500 hookworms produces measurable injury. Such intensities of infestation should be regarded as true hookworm disease. Light hookworm infestation (from one to 100) produces no measurable retardation in the normal development of children of school age, nor is the hemoglobin of this group reduced to a measurable degree. An infestation of twenty-five worms may be considered as the economic base line of cure. An infestation of twenty-five worms or less represents a carrier state, and is not true hookworm disease.

---

[1] Smillie, W. G., and Augustine, D. L.: *Hookworm Infestation,* Am. J. Dis. Child. 31: 151 (Feb.) 1926.

The prophylaxis of hookworm disease, as well as the cure of those infested, is complicated by the literally enormous numbers of persons concerned. The approach to a problem of such magnitude often calls for compromises that are not necessary under less formidable conditions. The treatment that may advantageously be accorded to a few patients cannot always be extended with equal thoroughness when many thousands are involved. This represents in some measure the situation prevailing with respect to hookworm infestation. Accordingly, if one is justified in regarding the latter from a quantitative or intensity standpoint and considering persons showing the mildest types of involvement and no physical injury as "carriers" rather than "patients," it may be advisable at present to concentrate personal attention on those in greater need of immediate relief. Smillie and Augustine believe that elimination of carriers can be accomplished only by sanitation and education. These procedures, they aver, can be used effectively as the sole weapons of offense, and, in time, will eliminate both the disease and the carrier; but this method is very slow. It is a more economic and humanitarian policy to use treatment to control the disease and sanitation and education to eliminate the carriers.

CREEPING ERUPTION

About the middle of the sixteenth century, botany began to receive attention as a branch of knowledge which, as was then believed, it was important for physicians to study; and from that time forward, for more than two centuries, it formed a regular part of the curriculum in all the leading medical schools. The two chairs of botany and anatomy were not infrequently combined. Fallopius, for example, held the chair of anatomy, surgery and botany in the University of Padua.[1] This association has continued almost to the present generation in recognition of the helpfulness of botany in the search for drug-yielding plants or their cultivation. Zoology, on the other hand, has not been recognized to the same extent by the medical fraternity, except as certain specialized fields of biologic interest have become developed. It should be admitted that a somewhat desultory consideration has long been accorded to certain groups of animal parasites that may infest the human organism. Not until the significant rôle of insects as vectors of disease was clearly recognized did entomology, a branch of zoology, come into world-wide scientific prominence. Presently protozoology began to attract attention, until it has actually become the subject matter of serious consideration in every school of hygiene and public health;[2] and the study of zooparasites of other types is also being vigorously prosecuted.[3]

The helpfulness of highly expert knowledge of the lowlier forms of animal life for medicine has again been illustrated in a recent study[4] of "creeping eruption," a disease that has generally been considered a cutaneous myiasis or invasion of the skin by the larvae of certain flies. The location of such parasites is not confined to wounds or sores, but the larvae are wont to penetrate long distances through more or less superficial tunnels. The identification of the responsible agents as fly larvae has been positively made in a number of well authenticated instances. In rarer cases, nematode invasion of the skin has been reported. In a human disease having a linear skin eruption with an advancing end apparently caused by a migrating parasite, observers[4] in the United States Bureau of Entomology have detected a nematode larva approximately one-fiftieth inch in length and one twelve-hundredth inch in breadth. It was recovered from each of five excisions, representing four patients and as many different localities. The causal nematode is reported here for the first time and described under the name *Agamonematodum migrans* by Kirby-Smith, Dove and White. For the disorder occasioned by it, these investigators propose that the name "creeping eruption" shall for the present be specifically retained.

This cutaneous nematode is apparently not uncommon in at least the southeastern and southern coastal areas of the United States. Kirby-Smith has observed more than 2,500 cases during the fifteen years of his practice at Jacksonville. It has been seen also in the Carolinas, Georgia, Alabama, Texas and Oklahoma. Some persons are more susceptible to infection than others. White persons are more susceptible than negroes. Infection occurs more often in children than in adults, and is most frequent during the summer following rainy weather. The origin of some cases in proximity to sewage disposal suggests a possible relationship with intestinal worms of man, while other cases have originated at points distant from such likely sources of contamination. The evidence at hand tends to indicate that rats might be the normal host of the adult worm. Poultry, cats, dogs and other animals may possibly be concerned. Several promising modes of treatment have been proposed. Successful prevention must await further knowledge of the life history of the adult of the nematode parasite.

SALIVARY DIGESTION IN THE STOMACH

When saliva is admixed with hydrochloric acid even under conditions in which the resulting hydrogen ion concentration—the acidity, as it is now usually expressed—is small, the starch-digesting property of the secretion is rapidly destroyed. This is a fact demonstrated in many biochemical laboratories by medical students. A generation or more ago, after the discovery of this phenomenon of amylase destruction by the acid of the gastric juice, it was assumed that salivary digestion must necessarily come to an abrupt end as soon as the bolus of food admixed with salivary enzyme reached the acid-secreting stomach. The pioneers in this study failed to take into account the comparatively slow motility of the latter organ. Yet more than twenty years ago Starling[1] was wont to remind his hearers that the swallowed mass lying in the fundus of the stomach, impregnated with saliva and kept at the body temperature, is penetrated only with difficulty by any juice secreted in the stomach, so that, in those animals whose saliva contains ptyalin, the process of salivary digestion can go on unchecked, at any rate in the center of the mass, for from twenty to forty minutes.

Essentially the same conclusion regarding the persistence of the salivary digestion of starch in the stomach has recently been reached by Bergeim[2] of the University of Illinois College of Medicine. His studies of salivary digestion in the stomachs of normal men showed that, on the average, 76 per cent of the starch of mashed potatoes and 59 per cent of the starch of bread was converted to maltose, an additional percentage being changed to dextrins. This considerable degree of starch conversion was generally brought about within from fifteen to thirty minutes after the meal was finished, active amylase disappearing and free hydrochloric acid appearing simultaneously. Obviously, as Bergeim has pointed out anew, in disease one may expect salivary digestion to be influenced by the quantity and digestive power of saliva secreted and by the motility and secretory power of the stomach. In achylia, salivary digestion in the stomach will be undisturbed and will proceed to practical completion for this type of digestion. If the stomach possesses a bulky and highly acid residuum, such as is sometimes found in ulcer with retention, or if the secretory response of the stomach is rapid, salivary digestion will evidently stop sooner than it otherwise would.

The observations indicate that a rapid development of gastric acidity is not incompatible with a high degree of salivary digestion, because, if food is properly masticated and starch digestion allowed to proceed for fifteen minutes or so in the stomach, almost as much starch is broken down as when digestion can proceed for a longer time. For this the high amylase concentration of saliva is responsible. The use of amylase preparations in medicine has lost its former vogue. From the standpoint of "replacement therapy" there is little, if any, indication of serious need of them. With starch presented in readily digestible form, the salivary enzymes have great opportunity to promote its conversion to the desired alimentary products to be augmented by supplementary digestion in the long reaches of the intestine. Responsibility for proper digestion of starch is thus being transferred more largely to the technic of the food factory and the kitchen instead of the purveyor of digestive ferments.

Current Comment

THE OMENTUM

One will seek in vain in textbooks of physiology for any reference to the omentum; yet the pathologist is intimately concerned with its function. During health the omentum is a comparatively passive structure which, like many other parts of the body, would not even betray its own existence if no effort were made to discover it by anatomic search. A surgeon[1] has termed the omentum "the abdominal policeman," intimating that "it travels around the abdomen with considerable activity, and is attracted by some sort of information to neighborhoods in which mischief is brewing." Thus it happens that when inflamed or septic areas develop or foreign bodies are introduced into the abdomen, a reaction occurs which consists essentially in the walling off and isolation of the inflamed or injured area from the remainder of the abdominal cavity. The omentum becomes adherent to the offending zone and, when this is sufficiently small, encapsulates it. In explanation of these remarkable performances, the occurrence of active omental movement has sometimes been assumed. Although it is not easy, in view of the known structure of the tissue, to conjecture how intrinsic excursions of the omentum in the abdominal cavity can be brought about, the possibility has been taken into account by investigators, notably Florey and Carleton[2] of Cambridge and Oxford, respectively. Their experiments clearly establish that the omentum is totally incapable of any intrinsic activity of the organ itself; but it is moved passively by postural changes of the body, by the peristalsis of the alimentary tract, and occasionally also by movements of the diaphragm. Through such displacements of the abdominal structures, the omentum comes into contact with injured areas or foreign bodies. The mode of attachment consists in the long known production of a layer of fibrin at the point of contact. The power of fibrin production by the omentum is said to be far greater than is that of the peritoneum. According to the English students of the subject, leukocytic emigration also is prompt, so that in the course of a few days, organization of the fibrin layer by new blood vessels and fibroblasts results in the encapsulation of the offending zone by connective tissue fibers. In other words, the powers of adhesion and encapsulation are intrinsic, whereas the movements of the omentum are passive and extrinsic.

THE HEART IN MERCURIC CHLORIDE POISONING

The familiar picture of the consequences of ingestion of lethal doses of mercuric chloride includes a succession of symptoms that may develop with varying rapidity and often only slowly reach their terminal stages. Cramps, bloody vomitus and diarrhea often occur; anuria frequently follows an acute tubular nephritis; and death in uremia is a delayed feature. Acute collapse may occur, but it rarely terminates in an immediately fatal outcome. Thus, among more than half a hundred fatalities recorded within a few years by a single German observer,[1] only one occurred early. The cause of such occasional early deaths after acute mercurial poisoning, undeniable, though they are rare, remains to be accurately ascertained. Nephritis will not always explain them, for there may be circulatory collapse with little evidence of renal damage and without uremia. Kohn[2] has made electrocardiographic studies in experimental animals which suggest that direct myocardial injury may account in part, at least, for this early toxic death. The quantities of mercuric chloride per kilogram that showed this action were of the same order as might be assumed for absorbed mercuric chloride from the average amount ingested by human beings. The heart therefore deserves early attention in cases of such intoxication.

THE INTESTINAL PHASE OF GASTRIC SECRETION

The question of the mechanism of the secretion of gastric juice is a physiologic theme that deeply interests the clinician. The regulation of gastric digestion becomes a task for him not only in connection with alimentary disorders but sometimes also for the accomplishment of adequate nutrition, on which a patient's ultimate recovery or well being may largely depend. Not long ago, reference was made in THE JOURNAL[3] to the evidence for the existence of various "phases" of secretion into the stomach, notably the cephalic, gastric and intestinal. The gastric aspects have naturally excited discussion from the outset, notably since the pioneer and lately verified observations of William Beaumont on the effects of local stimuli to the gastric mucosa. The psychic factors have become recognized through the widely reported studies of Pawlow and emphasized by the work of subsequent investigators. There is a peculiar interest attached even in lay circles to the idea of a psychic influence on the work of the digestive organs; possibly it is thought to illustrate the much vaunted "power of mind over matter." The intestinal phase of gastric secretion, however, has for the most part been overlooked or neglected; yet it has no small importance from a clinical standpoint. The beautiful experiments of Ivy, Lim and McCarthy[4] at the University of Chicago show that the pouch of the entire stomach secretes gastric juice after a latent period of one or more hours, when a mixed meal is ingested and enters the intestine directly without contact with the stomach wall. The delay in the gastric response is presumptive evidence that the effective agent is to be found in products of digestion as they arise in the intestine; at any rate, meat, starch and fat as such do not act. Alcohol, a stimulant of gastric secretion, has long been known to act when introduced directly into the lower bowel; and water also stimulates, though not invariably. Perhaps the response in this case is due to the resulting increase in circulating blood, which in turn promotes secretion. From a practical standpoint it needs to be borne in mind that the intestine affords a pathway for stimulation of the gastric glands. In attempts to "spare" the latter, such "long distance influences" need to be taken into account.

THE SEARCH FOR ACUTE FEBRILE ANEMIA IS BEGUN

In a recent issue of THE JOURNAL,[5] reference was made to Moschcowitz's novel description of an "acute febrile pleiochromic anemia with hyaline thrombosis of the terminal arteries and capillaries." At the time, it was intimated that such precise formulation of nosologic data was likely to bring to light further instances of the same condition; for the history of medicine furnished many illustrations of how careful description of supposed rarities has made physicians more alert in discovering duplicates. A companion case to Moschowitz's[6] clinical entity has been reported by Brill[7] from Portland, Ore.; and he has in turn called attention to a comparable observation by Macintosh and Cleland[8] in Sydney, Australia. Three cases of an apparently identical morbid condition have thus afforded a fairly complete description of the clinical manifestations and pathologic anatomy of a disease unknown heretofore. Moschowitz has detailed some of the principal pathologic manifestations; Brill has succeeded in effecting a cure in one case through blood transfusions given in small amounts at frequent intervals; and the Australian clinicians, through isolation of bacteria from the tissues at necropsy, have raised the questions of a microbic etiology. Thus the problem of the newly identified acute febrile anemia is before the medical profession.

PROCEEDINGS OF THE DALLAS SESSION

MINUTES OF THE SEVENTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT DALLAS, TEXAS, APRIL 19-23, 1926

HOUSE OF DELEGATES

First Meeting—Monday Morning, April 19

The House of Delegates convened in the Baker Hotel, and was called to order at 10 a. m. by the Speaker, Dr. Fred C. Warnshuis, Michigan.

Preliminary Report of the Committee on Credentials

A preliminary report of the Committee on Credentials was submitted by the Chairman, Dr. J. D. Brook, Michigan, who reported that there had been filed with the committee registrations totaling 114 members with proper credentials.

The report of the committee was accepted.

There being no objections, the report of the Committee on Credentials was considered the roll call of the House. A quorum being present, the Speaker declared the House duly constituted and ready for the regular order of business.

The next order of business was the presentation, correction and adoption of the minutes of the Seventy-Sixth Annual Session. The Secretary announced that the minutes had been printed and sent to each member of the House of Delegates registered at Atlantic City, with a request for corrections, but that none had been offered.

On motion of Dr. A. T. McCormack, Kentucky, seconded and carried, the minutes of the last session were approved as printed.

Radiogram from Dr. Simmons

The Secretary read the following radiogram from Seapoint Cape, South Africa:

"Congratulations to delegates on Twenty-Fifth Anniversary. Creation of House made possible accomplishments of the quarter century. May Dallas session be glorious success. Regret absence. "GEORGE SIMMONS."

ADDRESSES OF EXECUTIVE OFFICERS

Address of the Speaker, Dr. F. C. Warnshuis

The Vice Speaker, Dr. Rock Sleyster, Wisconsin, took the chair, after which the Speaker delivered his address:

Members of the House of Delegates:

For the fifth time, by reason of your tolerance and kind consideration, I am privileged to preside during your annual deliberations and to address you at the opening session of this meeting. I would be unappreciative indeed did I fail to convey to you my hearty thanks for the trust you repose in me. It will be my purpose to acquit myself in a manner that justifies the confidence expressed. In doing so I bespeak your assistance.

DELEGATES' RESPONSIBILITY

As delegates, representing constituent units of our Association, a responsibility that extends beyond and supersedes personal opinions or quests is reposed in you. On various occasions the House of Delegates has been approached by individuals not included in its membership, requesting the passage of resolutions for personal and selfish interests, and not planned for the good of all. Each Delegate may well consider before introducing a resolution the reason for its introduction, and whether or not a personal consideration is involved.

By your action at our last session it was made possible that proposed resolutions could be sent to the Secretary one month prior to the convening of this House. There has been a negligible response. This procedure was advanced in order that your work might be expedited rather than to limit enactments. Your speaker will rule that, during this session, resolutions may be introduced during the first two sessions and that those subsequently presented will require unanimous consent or else conform to the provisions set forth in our By-Laws.

ASSOCIATION'S ACTIVITIES

By virtue of my office it has been my privilege to attend the meetings of the Board of Trustees. I would that it were possible for every Delegate to be present at the Board's sessions. I have been impressed by the earnest sincerity with which our Trustees assume the responsibility that we place on them. In considering the business matters that come before them, whether it be the purchase of a $65,000 press, the problems of a constituent county unit, legislative activities, public education, scientific work or what not, I have yet to see the faintest inkling of selfish quest or individual prejudice. Each transaction is considered from one fundamental basis, and that is the interest of the physician as an individual and the Association as a whole. I want to voice again the belief of this House that our confidence is well placed in our Trustees, and that they merit our heartiest thanks for their contribution of personal time and thought for the advancement of the profession's interests.

We are extremely fortunate in having executives who are intensely eager, forgetting self, in conducting our business and organizational affairs. The contributions they are subscribing, that which they are achieving, the example they reflect cannot but command respect and commendation. That same spirit and service characterize and permeate the entire personnel at Headquarters. A splendid loyalty to the profession predominates. I feel that we, as Delegates, representing our entire fellowship and membership, owe much of our present organizational stability to the work that is being accomplished by our officers and executives.

What the past year has wrought is clearly set forth in the report of the Board of Trustees. A delegate fails in his duty if he has not read this report. He doubly fails if he neglects to acquaint his state society with these reports of their parent national organization and neglects thereby to obtain whole-hearted interest and support in his state for the work that is being accomplished. Your Speaker is deeply impressed by the possibilities that can be made to result from the activities we are engaged in if our entire profession will but become actively concerned with them.

May I not urge on you that as you return to your state society you will avail yourself of the opportunity and devote time and effort in securing an increasing degree of interest and extended sustained support to these activities. Surely we can no longer stand by in placid attitude when the opportunity is ours to a greater extent than ever before, to set forth these ideals and aims of the medical profession.

As an Association, as units forming our federacy and as individuals, our professional and personal responsibility is divided into two general divisions: the pursuit of scientific study and research and the enhancing of our personal capabilities as physicians to apply these proved principles in the prevention and treatment of disease and, second, the education of the public as to the truths of scientific medicine.

Our professional standing, our scientific advancement, the sifting of the real from the unproved rests with those who are associated with our universities, laboratories and hospitals. In those environments they are able to pursue research and study of the problems partly or still remaining unsolved and establish on a sound basis that which scientific research has uncovered. These workers command our respect for unfolding the erstwhile mysteries of physiologic and biologic functions and the pathobacteriologic changes resulting in disease conditions. As they unfold and establish principles and tenets, he who is engaged in general or special practice must exhibit their application. He cannot remain five or ten years in the rear of the march of scientific progress. He will, if he fails to devote sufficient time each month to acquiring this knowledge. In failing in this, he lowers the profession's standing, for we are appraised not always as a group but as individuals. It therefore devolves on state and county units to pursue vigilantly a program of scientific activity that will enable its members to remain abreast of scientific progress and reflect that progress in their daily contact with their patients. They must guard against the mediocre, the obsolete, and bring up to standard the professional knowledge and work of their members. We lay ourselves open to justified criticism if organized medicine condones, by inactivity, the deficiencies and vagaries of its members. My earnest desire in this is for greater, well planned and concentrated instruction of members in order that they may receive sustained education abreast of the progress of our science. A higher, much to be desired standard and type of practice will then be evolved. This I hold to be an outstanding obligation of our county units—an obligation that is apparently neglected and to which state societies should devote thought and action. Your Speaker recommends that this House direct the Secretary to refer to our state societies this problem.

The second general division of associational responsibility is that of the educational enlightenment of the public as to what the science of medicine may and can achieve for man's individual and collective welfare. This is the greatest public contribution that we can make to all peoples. Our science has made wonderful strides. We are able not only to prevent but also to cure many of the physical ills that beset mankind. We can extend the span of life and enhance it. But of what avail is this ability if we fail to disseminate this knowledge to the public? The public has evidenced an increasing eagerness to receive facts regarding scientific medicine from sources that are authoritative. Our federacy is that source and agency. Our responsibility is an outstanding one. The duty is ours to expend greater time and effort in imparting this knowledge. To do so, we must with concerted, well thought action disseminate these scientific facts and refute the vagaries and fallacies of those who have, and are holding forth as pseudoscientists or as cultists and scientists on theories and principles that rest on a factless premise. By the imparting of the knowledge that we hold, by setting forth that which has been proved, we render a dual service to humankind in conserving physical health, and relieving them of human ills and in exposing those who are posing as possessed of ability to treat disease by means and vagaries that are scientifically valueless. The purpose of your Speaker in so expressing himself is to add emphasis anew to the importance of public education in scientific medicine, and to urge that this House take added action that will promote increased activity to that end.

STATE MEDICINE AND CONTRACT PRACTICE

This House of Delegates and the Judicial Council have defined and voiced opinions as to the Association's attitude toward so-called state medicine, contract practice and group practice. There can be no confusion, doubt or questioning as to definition, inclusiveness or policies, for our Association has very clearly set forth its position. In like manner, expression has been voiced in regard to clinics of the free, charity and "pay" classification. Notwithstanding this action, the resolutions adopted and the Judicial Council's activities, there are evidenced in many communities tendencies toward rapidly growing development of this type of medical practice. They are being aided, abetted and sponsored in many instances by medical men, members of constituent units and of our Association, who, hiding under the guise of public health education, seek to justify their actions and ignore in doing so the Association's enunciated policies. They defeat county and state societies' efforts toward regulation and direction of these forms of medical practice. Your Speaker does not purpose entering on a detailed discussion of the problems at this time, but he does desire to recommend that the House give consideration toward formulating some type of action that will consist of disciplinary measures whereby your former enactments will be observed and complied with by Fellows of the Association, who evidently consider themselves immune from your regulatory enactments. The query, hence, is propounded: Shall we not consider the recommendation and institution of procedure that will command compliance with the enactments of this Association?

PLACE OF ANNUAL MEETINGS

Our Association's annual meeting entails a tremendous amount of work to provide satisfactory arrangements for meeting places for the scientific sections, general meetings, commercial and scientific exhibits, in addition to hotel accommodations for those in attendance. From contact with our officers who are concerned with these details I am impressed with the labor and expense involved and the hundred matters that require adjustment as well as difficult local problems that call for finesse and judgment to overcome. There are but relatively few cities that afford satisfactory accommodations for the holding of our annual meeting. At times we condone unsatisfactory conditions and expend unnecessarily large amounts of money for alterations and building changes. It would therefore seem wise that we change our By-Laws, empowering the Board of Trustees to designate, after careful study and investigation as it only can through proper officers, the place for the holding of our annual meetings. Your Speaker therefore recommends that this comment be accepted as a notice of change in our By-Laws and that the Reference Committee on Constitution and By-Laws bring in the wording of such amendment for your further action at this session.

DEATHS

During the year there have passed on to eternal rest, Thomas McDavitt, Grover Wende, F. A. Stine and G. F. Keiper. Their demise is recorded in deep sorrow and with our sincere sympathy to their immediate relatives. Recognition is accorded to the time and labor they have contributed for the advancement of the interests of scientific medicine and our organization. We who are still privileged to serve must assume their tasks and carry on.

CONCLUSION

Your Speaker feels that, since each Delegate is actively alert to the purposes, activities and needs of our Association in its several professional and public contacts, further comment or discussion of our problems would at this time be superfluous. Your program of work, for this session, is well set forth in the reports of trustees, councils and committees. I am confident that your combined wisdom and their consideration will result in recording indicated action in a manner that will redound to your credit and inspire increasing confidence in your legislative acumen.

The address of the Speaker was referred to the Reference Committee on Reports of Officers.

Reference Committees

The Speaker resumed the Chair and announced appointments to reference committees:

SECTIONS AND SECTION WORK

T. B. Throckmorton, Chairman	Section on Nervous and Mental Diseases
B. R. Shurly	Section on Laryngology, Otology and Rhinology
J. L. Rothrock	Minnesota
W. P. Eagleton	New Jersey
W. G. Ricker	Vermont

RULES AND ORDER OF BUSINESS

H. P. Linsz, Chairman	West Virginia
E. M. Neher	Utah
W. R. Bathurst	Arkansas
W. H. Seeman	Louisiana
William Kuykendall	Oregon

MEDICAL EDUCATION

F. B. Lund, Chairman	Massachusetts
J. N. Hunsberger	Pennsylvania
J. A. Witherspoon	Tennessee
William Allen Pusey	Illinois
B. R. McClellan	Ohio

LEGISLATION AND PUBLIC RELATIONS

H. M. Brown, Chairman	Wisconsin
Donald Macrae, Jr.	Iowa
A. D. Dunn	Nebraska
W. A. Cook	Oklahoma
A. J. Bedell	New York

HYGIENE AND PUBLIC HEALTH

A. T. McCormack, Chairman	Kentucky
S. W. Welch	Alabama
C. E. Mongan	Massachusetts
C. E. Humiston	Illinois
L. H. McKinnie	Colorado

AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

J. W. Van Derslice, Chairman	Illinois
C. T. Pigot	Montana
D. E. Sullivan	New Hampshire
E. A. Hines	South Carolina
D. E. McGillivray	Washington

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

E. Eliot Harris, Chairman	New York
C. J. Whalen	Illinois
Holman Taylor	Texas
E. J. Goodwin	Missouri
A. H. Bunce	Georgia

REPORTS OF OFFICERS

A. W. Booth, Chairman	New York
V. G. Vecki	California
W. Gerry Morgan	District of Columbia
A. E. Bulson, Jr.	Indiana
J. N. Henry	Pennsylvania

CREDENTIALS

J. D. Brook, Chairman	Michigan
G. C. Madill	New York
C. E. Piersall	Nevada
G. C. Cottam	South Dakota
Henry Boswell	Mississippi

MISCELLANEOUS BUSINESS

B. L. Bryant, Chairman	Maine
Charles O'Donovan	Maryland
E. E. North	Missouri
M. L. Stevens	North Carolina
E. D. Ebright	Kansas

Address of President William D. Haggard

The Speaker introduced the President, Dr. W. D. Haggard, Nashville, Tenn., who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker, Members of the House of Delegates, and Ladies and Gentlemen:

Among the many activities of the Association during the last year, a persistent effort has been made to popularize the periodic health examination of the apparently healthy. This has been done by editorials, special articles, addresses by the officers of the Association, and especially by a meeting of the secretaries of the component state medical societies, for which a special two days' program was arranged to consider the question.

As an officer, I have labored in season and out of season to bring this matter before the attention of every state, county and local medical society that I have had the honor of addressing, together with many educational and other lay organizations.

Every other profession and utility is striving for service to its patrons. The annual health examination is a new type of service that the profession has never yet employed as a whole for the benefit of its clientele. There is no gainsaying the great importance and wonderful opportunity for the betterment of mankind, and especially in preventing future disability, than the universal health examination. It would add not only years to life, but life to years. It would in all reality increase the scope of each individual's life by detecting the insidious maladies of all types in their incipience. The skill of the physician could be utilized in the anticipatory prevention of the many maladies whose early recognition makes for cure. It would mitigate the age long wail of the medical profession that patients present themselves too late. This is particularly true of cancer and the precancerous lesion. The oftener the examination from head to toe, the surer the beginnings of new growths can be determined. If cancer alone were the only disease that could be detected by these examinations, it would be of incalculable benefit.

It is the insidious diseases of the great organs, the degenerative diseases, that especially go undetected unless an examination, even in apparent health, discloses their first evidences.

The greatest field of the physician, which has been so long neglected, is the health guidance of his clientele. His judgment, wisdom, experience and knowledge can be massed in an attack against all forms of abnormal and unhealthful living, bad eating, and environmental and occupational disorders.

Social hygiene, in its best sense and in its own most rightful application by a man of sane and practical experience, could be employed to throttle abnormal behavior tendencies and bad habit formations and in the training of character.

It is not only the physical handicap but also the mental and environmental that so often needs surveillance. Thus will the true physician come into his very own in the close and intimate management of the health and happiness of his patients and render a vital service for which no one else is so transcendentally fitted.

Blanks of the physical examination, including the history of the patient, which he himself can fill out, should be in the waiting room of every physician for the use of his office patients, with a little placard over it, as employed by the Pennsylvania Medical Society, inviting the patient to take a health examination blank, fill it out, and be examined that he may have better health and longer life.

When once inaugurated, there could be no objection to the physician notifying his clientele by mail that the yearly examination would be due on a certain date, just as dentists do about their prophylactic treatments. It is not only a courtesy but a valuable thing to the patient and would embolden a large percentage to apply for examination who would neglect it if not reminded of it.

Each medical society should determine its own charge, both minimum and maximum, which it thinks would be wise and reasonable for the annual health examination.

The publication of the "Manual for the Conduct of Periodic Examinations," which has been issued by the Association under the direction of the Bureau of Health and Public Instruction, is very complete and helpful and has been very well received by the profession. It should be in the hands of every physician in the United States.

It is obvious that mere propaganda, while all important in the beginning of a great movement of this sort, cannot realize its object unless it has as a basis a plan whereby every one in the profession can be brought to the acceptance and employment of the plan. It is clear that such a far reaching effort cannot rest on a few men or on the officers alone of the various societies, but it must be put in the hands of the individual members.

It would seem, therefore, that on the county society as a unit should be devolved the responsibility of giving every one of its members the information and the facilities, and further, through its cooperation, to bring the matter to the attention of every individual in the community.

To that end and to the practical utilization of the idea of periodic health examinations, the following plan has been elaborated by the retiring president as a suggestion in order to get the maximum number of patients examined by a maximum number of family physicians:

PLAN FOR PROMOTION OF PERIODIC HEALTH EXAMINATIONS

1. The House of Delegates should recommend to the thirty-four states that have not yet acted, that the manual be obtained from headquarters at cost price, together with a suitable number of examination blanks, and supplied to each individual member.

2. The House of Delegates should recommend to the county societies that a special meeting on this subject be held at least once a year in order to popularize the plan and bring it into being.

3. A medical society clinic emphasizing the need, value, method and technic in the conduct of health examinations, and their bearing on preclinical medicine, should be arranged by local or neighboring clinicians.

4. A strong, active committee in each county society on periodic health examinations should supervise the inauguration and perpetuation of the health examination.

5. A nation-wide educational campaign should be inaugurated during "Health Week," or some designated period in cooperation with the existing board of health or with some local activity, such as the Anti-Tuberculosis Association, or other lay organization, to interest the civic clubs and other organizations in the great importance and benefit to be derived from this plan. Health parades with banners carried by Boy Scouts, films, large posters, and folders could be utilized, as was so successfully done by the Illinois Medical Society.

6. A statement in the nature of a circular letter should be prepared by the county society and sent impersonally as a statement from the county society to the clientele of the various members, calling their attention to the importance of the annual health examination and urging their acceptance of it at the hands of their physicians.

7. Many organizations, lodges, clubs, large industrial corporations, etc., could greatly facilitate the idea by having cards mailed to their various members on their birthdays, urging the importance of the acceptance of the birthday physical examination.

8. The medical society as such should start the campaign by having as many of the individual members as possible to undergo the examination, first, as an educational measure and, secondly, to imbue the individual members themselves with the importance and far reaching value of the plan. This method was employed by the King's County Medical Society. Nothing will stimulate the universal application as much as the profession themselves who so sorely need it, utilizing the idea for their own benefit as well as for the advancement of the general scheme.

9. The press should be requested to carry articles prepared and issued by the county society, preferably unsigned, as a news article or under the signature, if desirable, of the officers of the society, explaining the importance of periodic physical examinations and the benefit to be derived by the health client.

These recommendations are to strengthen the work already done, crystallize it and have it activated by the House of Delegates.

No more humane, scientific and socially and economically beneficient movement for the well being of the American people could be fostered and put into nation-wide practice than the universal periodic health examination by the American Medical Association.

Address of President-Elect Wendell C. Phillips

The Speaker introduced the President-Elect, Dr. Wendell C. Phillips, New York, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

Since the World War, the histories of foreign nations have been marked by intense nationalism. This nationalistic trend has led them to take advantage of every possible opportunity to exploit their merits, and medical science has been no exception. Unfortunately, many of the medical discoveries thus far proclaimed and promoted as national interests have not fully proved their worthiness. In other words, the rush for publicity has led the promoter far afield from the pathway of proved science.

From Switzerland has come the Spahlinger treatment of tuberculosis; from England, the Gye-Barnard work on cancer, also the Dreyer vaccine for tuberculosis; from France, the Calmette work on vaccination against tuberculosis with living organisms; from Germany, Blumenthal's investigations on cancer, and from Denmark, Sanocrysin.

Not one of these discoveries has thus far been established as of great value, although, according to Park, the Calmette work on vaccination seems to possess possibilities of virtue.

The United States, on the contrary, without having made any great pretense to the forcing of its scientific discoveries into the nationalistic program, has given to the world remarkable discoveries and scientific advances in medicine.

The work of the Dicks and of Dochez and Blake on scarlet fever seems to be established on a definite scientific basis. The discoveries made on the virtues and the relation of light to rickets represent another real achievement in the advance of science.

The toxin-antitoxin prevention of diphtheria has been definitely and positively proved. An intensive antidiphtheria campaign carried on in the city of Auburn, N. Y., has been so successful that no deaths from diphtheria have occurred in that city for the last two years. An antidiphtheria campaign now going on in New York State carries the slogan "No diphtheria in New York State in 1930," and the state commissioner of health believes that this is possible. It would seem that the future holds out hope that diphtheria—the dread destroyer of child life—may ultimately disappear, at least as an epidemic disease.

We may also claim a distinct advance in studies related particularly to the elimination of scarlet fever, measles, and possibly whooping cough. Moreover, the United States may truly be called "teacher to the world" in organization and methods of preventive medicine.

All these are distinct achievements in the advance of medical science, but in this country they have not been promoted in a nationalistic spirit. They have been offered freely to the world as our contribution. Let us not hesitate to do all in our power to give our own people the knowledge and the benefit of these discoveries. The public should know that children may be made immune from diphtheria as surely as from smallpox, and every physician should endeavor to persuade all patients to safeguard their children, especially those of preschool age, by the employment of preventive treatment.

During the last few years, many of our leaders of medical thought, and particularly those clothed with the responsibility of outlining medical policies, have given serious consideration to the subject of public health education. There has been a slight awakening of the medical conscience as to the trusteeship of physicians as promoters of individual and community health. These pioneers have become alive to the fact that physicians only are qualified by heritage, by education and by experience to give to the public the basic principles of health preservation, and the protection of life that is afforded by sanitation and the scientific application of all the phases of preventive medicine. Given such responsibility, I ask you in all seriousness whether the medical profession of the country has ever lived up to its great opportunity to teach the people how to keep well. It sounds like a simple thing to do, but the reticence of medical men and the innate fear of publicity, the supposed restriction of ethical limitations, have tended to prevent these great educators from fully covering this proper field for a physician's activity.

Nevertheless, there has gradually developed on the part of the public demands for public health education. Gradually, great newspapers and newspaper syndicates are coming to realize that public health knowledge is a valuable commodity for which the people are willing to pay. This tendency is leading newspapers, magazines and newspaper syndicates to realize that the public must be given the true facts regarding individual and community health. This further knowledge in turn is showing its influence by the gradual elimination from these publications of the publicity which is sought by nostrums, cults, quackery and other menaces to the public health. This naturally engenders a desire to purvey only well founded information regarding health matters.

In the quest for such information on the part of great publications, they have learned that organized medicine is the only possible source from which correct information can be obtained. Our headquarters is well equipped to furnish every form of advice and counsel that any publication may need regarding irregularities and fakes. We are able from headquarters to supply health educational material covering a wide variety of topics, but we must not forget that a hundred and fifteen million people in the United States need information and education both as individuals and as communities. The American Medical Association has positively and definitely entered the field of public health education. We have shown this in various ways, particularly by the publication of *Hygeia,* which is distinctly a public health journal, devoted to individual and community health. I am happy to say that this journal is proving its worth and is rapidly becoming the text for sound public health principles.

We have also endorsed the scheme for periodic health examinations, and we are beginning to promote this wise, humane, healthful program through our county and state societies. We are also entering into cooperative relationship with great newspaper and magazine agencies, through which information from the highest medical sources is furnished to the public over the names of the men who write the articles. These are all steps in the right direction, but as I see it they mark only the entering wedge into what must eventually become universal health education, participated in by every medical practitioner as one of the basic duties of his profession. There should be in the United States a great public health preventive medicine university with a hundred and fifty thousand physicians as teachers. Universal health education of the public received from a properly informed physician will eventually result in a new type of patient and an increased activity for the physician, which will greatly enhance not only his field of service but also his financial status.

I am convinced that modifications in the undergraduate curriculum that will provide for broader education in preventive medicine, public health, psychology and sociology should receive serious consideration on the part of medical educators.

To this end I recommend that the House of Delegates urge every practitioner of medicine to become a public health educator in the broadest sense of that term; that the American Medical Association devote sufficient time to the development of ways and means for properly conveying personal and community health education; and that either by the appointment of a special committee or through one of the bureaus of the Association an intensive survey of the general subject of public health education should be inaugurated and reported on at the 1927 meeting of the House of Delegates.

REPORTS OF OFFICERS

Report of Board of Trustees

Dr. Edward B. Heckel, Pennsylvania, read an abstract of the report of the Board of Trustees. The report was referred to the Special Reference Committee on the Report of Board of Trustees.

Dr. William Allen Pusey, Illinois, said: "The report in connection with the medical relief in times of disaster was taken up in conference with the surgeon generals of the several departments and with the executive officers of the Red Cross, and they gave it their entire approval. Surgeon General Ireland, however, suggested that by a little change in phraseology, we make it plain that we had to do clearly with medical relief. So with permission we would like to change the report from 'Report of the Committee on Disaster Relief' to 'Report of Committee on Medical Relief in Disaster,' and to change the several phrases throughout the report, adding 'medical' before 'disaster' in connection with it to indicate more clearly that this is a matter of medical relief."

Resolution in Memory of Thomas A. McDavitt

On motion of Dr. E. B. Heckel, Pennsylvania, Dr. A. R. Mitchell, Nebraska, read the resolution adopted by the Board of Trustees in memory of Dr. Thomas A. McDavitt, deceased:

> Dr. Thomas McDavitt, for thirteen years a member of the Board of Trustees of the American Medical Association, and for two years its chairman, died at his home in St. Paul, Minn., March 4, 1926.
>
> Dr. McDavitt was born in St. Louis, Mo., May 15, 1857, graduated from the Chicago Medical College in 1879, and entered on the practice of medicine at Minneiska, Minn., immediately thereafter. In 1891 he located in St. Paul and was engaged in practice in that city, specializing in ophthalmology and otolaryngology, until the time of his death.
>
> The son and the grandson of physicians, Dr. McDavitt had instilled in him from his childhood the high principles and honorable traditions of the profession in which he served for nearly forty years. He was thoroughly loyal to the ideals of the true physician, and stood with all his strength against any effort to drag them down.
>
> Early in his professional career Dr. McDavitt identified himself with medical organization and gave himself freely to its advancement. For nearly twenty years he was secretary of the Minnesota State Medical Association. At four annual sessions of the American Medical Association he served as a member of its House of Delegates, and in 1913 was elected as one of its Board of Trustees, in which capacity he served continuously until his death. As chairman of the Finance Committee, as a member of the Executive Committee and of the Committee on Scientific Exhibit, Dr. McDavitt rendered invaluable service to the Board of Trustees and to the Association. He looked on his duties seriously, and his every official act was performed with the most conscientious regard for what he believed to be for the best interest of the medical profession as represented in and by the American Medical Association. Always tolerant and considerate of the views of others, Dr. McDavitt was none the less guided by his own convictions, formed after mature deliberation.
>
> In his official and personal relations with his fellows, his every act was marked by high minded courtesy. Because of his fidelity to his every trust, his unswerving loyalty to his profession, his kindly bearing and his willingness to do his full part in every task, he won and held a high place in the esteem and affections of those who were privileged to serve with him on the Board of Trustees.
>
> Dr. McDavitt served his state with the same fidelity that characterized his service as an officer of this Association. For fourteen years he was secretary of the Minnesota State Board of Medical Examiners. In this capacity he stood between the people of his state and unqualified persons who sought license to practice the healing art. He demanded that the terms of the law be complied with, and was uncomprising in his stand against quackery and fraud.
>
> In the affairs of the Federation of State Medical Boards of the United States, Dr. McDavitt took an active part and always supported the efforts of this and other agencies to secure efficient medical service for the public. Be it
>
> *Resolved,* By the House of Delegates of the American Medical Association, that through the death of Dr. Thomas McDavitt this Association has lost a friend and counselor who, through his untiring and devoted service, played an important part in its development and in extending its influence as a scientific society and its benefits as a philanthropic organization. And be it further
>
> *Resolved,* That while we bow in sorrow that our friend and Fellow has passed on and that we are deprived of his companionship and helpful counsel, we are deely grateful for the privilege of our long association with him and revere his memory, because of his work for this Association and because of his devotion to the noblest traditions of our profession.

Report of Secretary

Dr. Olin West presented an abstract of the Report of the Secretary. The report was referred to the Special Reference Committee on the Report of the Board of Trustees, so far as matters that are reported on by the Secretary are related to subjects reported by the Board of Trustees. That part referring to amendments to the Constitution and By-Laws was referred to the Reference Committee on Constitution and By-Laws.

Supplementary Report of Judicial Council

Dr. M. L. Harris, Illinois, Chairman of the Judicial Council, presented a supplementary report as follows, the report of the Judicial Council having been printed in the handbook:

During the past year there have been submitted to the Judicial Council, for decisions, questions that have made it clear to this Council that a few slight changes are desirable in our fundamental law if consistent and effective decisions are to be made possible.

As the matter stands at present, there is a lack of uniformity in the laws of the several county societies and state associations, so that when appeals are taken to the Judicial Council, the Council finds itself unable to render consistent decisions owing to irreconcilable contradictions found in the laws of the societies or associations taking the appeal. The appeals that give rise to the greatest difficulties are those which involve a question of membership. It seems to be quite generally recognized that the county society has the sole right to determine who shall or shall not be admitted to membership. As membership in a state association and in the national association is made dependent on membership in a county society, it is provided in the laws of many state associations that a physician who has been refused admittance to his county society may appeal to the council or board of censors of his state association and in some instances to the House of

Delegates, and the board of censors may overrule the action of the local society and direct that the person be admitted to membership. It is at this point that the difficulties arise. Should the board of censors or the House of Delegates overrule the action of the local society and direct that the rejected person be admitted to membership, there is no way of enforcing the mandate.

Of course, the state association may revoke the charter of a local society, which may be likened to killing the goose to get an egg which, after all, may be bad. Certainly the remedy is too destructive, but without some remedy the situation reaches an impasse which the Judicial Council is unable to bridge over.

Appeals have come to this Council in which diametrically opposite conditions are found to exist. For instance, a local society refused to admit a physician to membership, and an appeal was taken to the state council, which overruled the action of the local society and directed that the physician be admitted to membership. The local society refused to comply with the order of the state council, and the matter was referred to the Judicial Council.

Again, a local society admitted to membership a physician that the state association considered most objectionable and directed that the local society expel him. The local society replies that the physician in question is *persona grata* to its members and refused to comply with the demand of the state association.

The Judicial Council is without power to act in either case. In the one instance, local prejudice or personal animosity prevents a good man from becoming a member of his state and of the national association, and in the other instance, local indifference forces a most undesirable man into the state and national associations.

At present there is no adequate remedy in such cases. We believe that the difficulty may be overcome in one of two ways:

The local society may not be the sole or final judge of who shall be admitted to membership, or some provision may be made by which the state and (or) national associations may, under certain conditions, determine its own membership.

It does not seem feasible or perhaps possible to remove from the local society the right to judge as to who shall be admitted to its membership. The attempt to force a local society to accept as a member one who has been rejected by a fair vote of the society can result only in disaster to the organization. On the other hand, local prejudice or personal animosity or spite may, as has already come to the attention of this Council, by keeping a man out of his local society, unjustly debar him from membership in our organization. This injustice may be remedied by making some provision by which one who has been unjustly kept out of his local society may become a member of his state and thus of the national association.

No one should be permitted to apply directly to the state association for membership unless and until he has been definitely refused admittance to his local society and until he has appealed his case to the board of censors or council of the state association, and only then provided the board of censors or council has given his appeal a fair hearing and is convinced that he has been unjustly kept out of his local society, and that it is impossible to reconcile the local society to admitting him to membership, and provided further that the board of censors or the state council recommends him for membership in the state association. The state House of Delegates may then elect him to membership, in which case he would thereby become a member of the American Medical Association.

The House of Delegates of a state association should also have the power to expel a man from membership, in case the local society refused to do so, on the advice and recommendation of the board of censors or council.

The House of Delegates of the American Medical Association, on the recommendation of the Judicial Council, should have the power to expel a member in case the state association and local society refused so to do.

The Judicial Council suggests that the House of Delegates of the American Medical Association and of the several state associations make such amendments to their By-Laws as will make effective the foregoing recommendations.

The report of the Judicial Council, taking into consideration certain changes in the Constitution and By-Laws, was referred to the Reference Committee on Constitution and By-Laws.

Report of Council on Medical Education and Hospitals

Dr. N. P. Colwell, Illinois, presented an abstract of the report of the Council on Medical Education and Hospitals. The report was referred to the Reference Committee on Medical Education.

The Speaker drew to the attention of the Reference Committee on Medical Education the instruction of the House that was given at the St. Louis session and repeated at the San Francisco session at which this Council was charged with taking up the study of the nursing problem and bringing some definite report to the House.

Report of Council on Scientific Assembly

Dr. J. Shelton Horsley, Chairman of the Council on Scientific Assembly, read the report, with the following interpolation after the section referring to the Section on Stomatology:

Of course, it is highly important that we have some contact with dentists. Only two papers at the last session of the Association could be classed as stomatologic papers. The others could be assigned to other sections. It seemed unnecessary to continue a section with such small attendance on that particular subject, whereas it could be distributed among other standard sections.

The report was referred to the Reference Committee on Sections and Scientific Work.

Report of Committee on Narcotic Drugs

Dr. W. C. Woodward, Chicago, read the report of the Committee on Narcotic Drugs:

The House of Delegates, at its last meeting at Atlantic City, appointed a committee on narcotic drugs. The main committee consisted of: Dr. William C. Woodward, Chairman, Chicago; Dr. S. Dana Hubbard, New York; Dr. C. G. Jennings, Detroit; Dr. Alexander Lambert, New York; Dr. Dean Lewis, Baltimore; Dr. George McCoy, Washington, D. C.; Dr. Olin West, Chicago, and Dr. Orrin S. Wightman, New York. The Advisory Committee consisted of: Dr. Ray Lyman Wilbur, Stanford University, Calif.; Dr. Frank Billings, Chicago; Dr. Hugh Cabot, Ann Arbor, Mich.; Dr. James F. Coupal, Washington, D. C.; Dr. Hugh S. Cumming, Washington, D. C.; Dr. George E. de Schweinitz, Philadelphia; Dr. William D. Haggard, Nashville, Tenn.; Dr. Merritte W. Ireland, Washington, D. C.; Dr. Franklin H. Martin, Chicago; Dr. William E. Musgrave, San Francisco; Dr. Wendell C. Phillips, New York; Dr. William A. Pusey, Chicago; Dr. George H. Simmons, Bromsgrove, England; Dr. Charles T. Sturgeon, Los Angeles, and Dr. Hubert Work, Washington, D. C.

The committee has held one meeting during the year. As the result of that meeting, the attention of the committee was called to the apparent inadequacy of instruction in medical schools with respect to narcotic addiction. It was voted to bring this matter to the attention of the Council on Medical Education and Hospitals and to the attention of the House of Delegates.

On the basis of a letter received from the Surgeon General of the Army, Dr. Merritte W. Ireland, a resolution was adopted recommending that the Board of Trustees approve a policy of turning over narcotic drugs confiscated by the customs service and Bureau of Internal Revenue, not necessary for the current uses of the government, to the war and navy departments in sufficient quantities to build up a reserve of these drugs for use by the army and navy in case of war.

The report was referred to the Committee on Hygiene and Public Health.

Report of Committee on Accidents from Zinc Stearate

Dr. Isaac Abt, Illinois, read the report of the Committee on Accidents from Zinc Stearate Dusting Powders:

The committee has held one meeting during the year, and Dr. Woodward has been in conference with the manufacturers. Progress has been slow. We have insisted that the package be of metal or that the zinc stearate be contained in a metal box and that it have a self-closing device. The Illinois State Board of Health, through its secretary, has passed regulations insisting that these recommendations made by this committee be complied with. I ask that the committee be continued in some way or other so that something may finally be accomplished.

The report was referred to the Reference Committee on Hygiene and Public Health.

Report of Committee on Trachoma Among Indians

Dr. Wilder, Section on Ophthalmology, read the report of the Advisory Committee to Commissioner of Indian Affairs on Trachoma Among American Indians:

In suggestions offered to the Commissioner of Indian Affairs in regard to the problem of the control of trachoma among the Indians, the committee urged the importance of a careful survey with complete records to determine the prevalence of the disease among the members of the various tribes and nations of Indians.

The committee also urged the importance of prevention of the spread of the disease among Indians not already affected, by proper segregation of active cases in schools and villages so far as feasible, and also by a campaign of education as to the manner in which the disease is conveyed from one to another and the simple measures of cleanliness that will prevent such spread of the trouble.

The committee was gratified to hear from the commissioner that its suggestions were accepted and are being acted on. In a communication of Feb. 16, 1926, he says:

> The work of reducing the morbidity for trachoma has been aggressively carried on the past year. We are continuing our Southwestern trachoma campaign, with three units working. During the last fiscal year our special physicians examined a total of 68,223 Indians, and operated on 8,455. In addition, they treated 5,581 without surgery. This does not include the patients operated on and treated by the regular physicians. We have established a temporary trachoma hospital at Albuquerque with bed capacity for twenty patients, which has been operating at capacity during the greater part of the time. We have also established a trachoma unit at the Laguna, N. M., Sanatorium, and it is doing excellent work.
>
> In addition to the active measures, we have been stressing the educational and prophylactic phase. We are enclosing a circular that has recently been sent out to the service. In accordance with the suggestions of your committee, we have designated two annual trachoma weeks, during which all workers in the service, including missionaries and ministers, are requested to stress the importance of this problem.
>
> In concluding, the office wishes to express again its appreciation for your helpful suggestions and assistance, and signify its hopefulness that the American Medical Association will continue the services of the committee at its next annual session.

Again in a letter of March 2, 1926, he says:

> Receipt is acknowledged of your letter dated Feb. 27, 1926, concerning the trachoma work in the Indian Service. Concerning the suggestion of your committee that a complete survey is necessary, the office is now making up a permanent record of trachoma at each agency and school, and we hope eventually to get a complete survey. We now keep a monthly record which will show the number examined, the cases found, and the disposition of each case by jurisdictions.

The circular referred to is directed to superintendents of Indian schools and physicians in the service, and insists on certain hygienic details in schools and meeting places looking toward the prevention of the spread of the disease.

The committee recommends to the House of Delegates the appointment of an additional member to the committee, Dr. Francis I. Proctor, formerly a practicing ophthalmologist in Boston, now residing in Camden, S. C., who is much interested in the subject, and who has time to devote to it.

The report was referred to the Reference Committee on Hygiene and Public Health.

NEW BUSINESS

Resolution on Changes in Premedical Courses

Dr. Southgate Leigh, Virginia, read the following resolution, which was referred to the Reference Committee on Medical Education:

> WHEREAS, The Council on Medical Education and Hospitals has already made certain investigations looking to changes in premedical courses so as to enable students to graduate in medicine at an earlier age than is now possible, and
>
> WHEREAS, Former President William Allen Pusey, in his address before this body, urged that the medical course itself be shortened by one year, therefore be it
>
> *Resolved*, By the House of Delegates that the Council be requested to consider feasibility of allowing medical students credit for courses taken during the summer months, in a manner similar to the plan followed in the academic departments.
>
> The Council is further requested to confer with the various medical schools, asking their cooperation in this important movement.

Resolution on Official Recognition of Irregular Practitioners

Dr. Southgate Leigh read the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

> WHEREAS, Through the expenditure of large sums of money, and the employment of prominent and influential individuals to represent them, the irregulars are making systematic and strenuous efforts to obtain official recognition in every state in the Union, and,
>
> WHEREAS, Many irregulars are illegally practicing in various states, and, through financial and influential backing, are making successful efforts against prosecution, and
>
> WHEREAS, In both of these matters there has at times been a lack of systematic and determined effort to thwart their aims,
>
> *Resolved*, By the House of Delegates that the Trustees be requested to take the necessary steps to aid and direct the profession in the various states properly to combat these vicious movements.

Resolutions on Trained Nurses

Dr. E. Eliot Harris, New York, read the following resolution, which was referred to the Reference Committee on Medical Education:

> *Resolved*, That there is a great need throughout the country for a basic trained nurse, and that all pupil or student nurses shall receive basic training in training schools connected with hospitals giving courses of two years. The curriculum should be thoroughly revised so as to provide bedside instruction, class room lectures and demonstrations and, above all, the teaching of the art of nursing by precept and example so as properly to fit the pupils or students for their work as nurses in the hospitals and in the homes.
>
> Graduates, after passing the state examination, should be registered as trained or, if preferred, registered nurses. Such trained or registered nurses may become public health or other specially designated nurses after being properly admitted to postgraduate schools for nurses and passing the required examination.
>
> *Resolved*, That the Board of Trustees appoint a committee on nurses and nursing education to investigate and report to the next House of Delegates the results of its investigation and constructive thought on the nursing question and especially on the subject of increasing the number of bedside nurses throughout the several states; the Committee on Nurses to be empowered to confer with the National Nurses Association, hospitals and other committees having similar objects.

Resolutions on a Home for Incapacitated Practitioners

Dr. D. E. Sullivan, New Hampshire, read the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

> *Resolved*, That the President be, and hereby is authorized and directed to appoint a committee of five representing the different sections of the country to make a survey of the physical condition and financial status of its members who are incapacitated for earning their support by the practice of their profession with the objective of establishing, managing and sustaining a home or homes for their care and maintenance, and be it further
>
> *Resolved*, That the said committee is directed to make a full and comprehensive report of its findings with recommendations to the annual meeting of the House of Delegates in 1927, and the Board of Trustees is hereby empowered to appropriate such sum of money as may be necessary to carry into effect said survey.

Resolutions on Expert Opinion Evidence

Dr. G. E. Follansbee, Ohio, introduced the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

> WHEREAS, The present court procedure in presenting expert opinion evidence in both civil and criminal cases has in many instances brought public criticism and disgrace on both the legal and the medical professions, and

WHEREAS, The present procedure, in many cases, is believed to defeat the administration of even handed justice, and to operate notoriously in favor of the rich as compared to the poor before a court on similar charges, and

WHEREAS, An effort is being made in many states by the bar associations and medical societies of those states to correct such maladministration of justice, and to relieve the legal and medical professions of the public criticism now received, and

WHEREAS, The American Bar Association is actively pursuing the foregoing laudable effort, therefore be it

Resolved, By the House of Delegates of the American Medical Association, that it recognize the urgent need for such remedial legislation and such change in court procedure as will correct the abuse of expert opinion evidence, that it approve the efforts of the various bar and medical associations, that it strongly favors the use of experts appointed by the courts as a corrective to the present abuse, that it believes the expert opinion witness should be allowed to present and read a written opinion based on examination and not on a hypothetic question, that fees due expert opinion witnesses appointed by the court should be fixed by the court and taxed as a part of the cost in the case, and be it

Resolved, That the American Medical Association offers its cooperation by such means as lies in its power to promote such legislation as will be mutually satisfactory to the legal and medical professions toward the correction of present unsatisfactory procedure of presenting expert opinion evidence, and the Board of Trustees is hereby requested to use the facilities of this organization in such a way as to give effect to the sentiments expressed in this resolution and, be it further

Resolved, That a copy of this resolution be sent to the American Bar Association

Resolution on Ad Interim Meeting

Dr Wells P Eagleton, New Jersey, presented the following resolution, which was referred to the Reference Committee on Constitution and By-Laws.

The delegates from the Medical Society of New Jersey are instructed to use their influence and vote

1 That an ad interim meeting of the House of Delegates of the American Medical Association be held at the headquarters of the Association annually, as in the opinion of New Jersey it is impossible for the House of Delegates to do its full duty by the medical profession by meetings but once a year during the scientific session

2 That the following words be added to Chapter III, Section 1, of the By Laws following the word "Association"

"An ad interim meeting shall be held at the headquarters of the Association annually"

Resolutions on Contract Practice

Dr A D Dunn, Nebraska, read the following resolution, which was referred to the Reference Committee on Legislation and Public Relations.

Inasmuch as contract practice is absorbing an ever increasing portion of general medical practice on account of the rapid development and concentration in business and industry, and inasmuch as brokers under the guise of health, accident and sickness insurance in which they purport as middlemen to sell medical services to the laity or entering the field of medical practice, be it

Resolved, That 1 The whole matter of contract practice be investigated under the direction of the Judicial Council

2 The trend and dangers to patient and profession inherent in this movement be analyzed and clearly set forth

3 Recommendations as to the policy of the American Medical Association toward contract practice, its functions, limitations and control be submitted to the House of Delegates for action at its annual session in 1927

4 Systematic effort be made to get clearly before the constituent societies the results of this investigation and whatever action the House of Delegates may take in the matter

Adjournment in Honor of Deceased Colleagues

Dr A T. McCormack, Kentucky, moved that when the House of Delegates adjourned, it adjourn in honor of the memory of Drs Stine, Keiper and Wende, three of our colleagues who have been lost to us during the year

The motion was seconded

Dr. Emmet Keating, Illinois, suggested as an amendment that Dr McDavitt's name be added to the list

The motion was carried as amended

Communications

The Secretary read messages from Dr. G E de Schweinitz, the Philadelphia County Medical Society, and the American College of Surgeons The communication from Dr Martin, American College of Surgeons, as the Board of Trustees has always determined the advisability or desirability of sending such delegates, was referred to the Board of Trustees

The meeting adjourned at 12 30 p m

(To be continued)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC)

CALIFORNIA

Typhoid Outbreak at Calexico.—An outbreak of typhoid fever, involving sixty-seven cases up to April 15, is reported by the California State Board of Health at Calexico in Imperial County, near the Mexican line All of the cases reported have occurred among consumers of milk from a single dairy As a result of an investigation made by the state epidemiologist, Dr Charles H Halliday, the source of the outbreak was traced to a "missed" case on the dairy Pasteurization of all milk supplies was ordered by the local health officer, Dr Alfred L Heck, immediately on the discovery of the first case The state health department predicts the development of a total of at least 100 cases in the present epidemic A complete investigation has been made and the epidemic is under control

State Medical Meeting—The fifty-fifth annual session of the California Medical Association will be held at Oakland, April 26-May 1, under the presidency of Dr Edward N Ewer of that city The first two days will be given over to preconvention clinics at the Providence, Merritt and Fabiola hospitals, they will be conducted by Dr Gabriel Tucker of the University Hospital, Philadelphia, Dr. Emil G Beck Chicago, and Dr John de J Pemberton, Mayo Clinic, Rochester, Minn, the afternoons of the preconvention days will be given over to golf Headquarters will be at the Hotel Oakland, Thirteenth and Harrison streets, the addresses of the retiring and incoming presidents will be delivered at the first general session at 10 o'clock, April 28 the second general session will be at the same hour, April 29, and will be addressed by the three visiting speakers noted above and by Col Edward L Munson, Medical Corps, U S Army Among others, Dr Ray Lyman Wilbur, president of Stanford University, will address the third general session, April 30, at 10 o'clock, on "The Deficiencies of Modern Medicine" There will be a smoker following the meeting of the house of delegates, Wednesday evening, and at that time, a musicale for the ladies, a dinner dance Thursday evening, and on Friday evening a bridge tournament Other entertainment and luncheons have been arranged for various groups

DISTRICT OF COLUMBIA

Personal—Dr William Calhoun Stirling, Jr, has been appointed associate professor of genito-urinary surgery at Georgetown University Medical School, Washington——Dr Arthur G Coumbe, Washington, has been appointed manager of the U S Veterans' Bureau office in Honolulu, Hawaii——Dr Harvey W Wiley addressed the Philadelphia Forum, April 8, on "Living Longer—How Can it Be Done?", this was the occasion of the observance of health day in Philadelphia, a trophy was presented to the school that won the highest average in health sanitation obtained in competition with twelve junior high schools in the city——According to *Science*, Dr Victor C Vaughan will attend the third Pan-Pacific Science Congress, to be held in Tokyo, October 27-29.——Lieut Col Charles F Craig, Medical Corps, U S Army, has been appointed director of laboratories and of the department of clinical pathology and preventive medicine at the Army Medical School

CHICAGO

Fund for Cancer Research—Mr E F Holmes has bequeathed $100 000 to the University of Chicago to further research on the problem of cancer, Miss Harriet F Holmes, a daughter, has been associated with Maude Slye, Ph D, in cancer research at the university for many years

Tuberculosis Conference—For the first time in years the Mississippi Valley Conference on Tuberculosis will be held in Chicago, June 14-17, at the Edgewater Beach Hotel There will be representatives from the tuberculosis associations of Ohio, Indiana, Illinois, Michigan, Wisconsin Iowa, Missouri, North Dakota, South Dakota Minnesota and Nebraska The purpose of the conference will be to discuss plans for future needs in tuberculosis work

Institute for Juvenile Research.—Founded sixteen years ago as a research organization connected with the juvenile court, the Institute for Juvenile Research now is operated by the state. Friends of the institute are raising $275,000 to finance a five year research program; they recently held a luncheon at the Hotel Sherman, which was attended by more than a thousand persons. Among the speakers were Dr. Adolf Meyer, Henry Phipps professor of psychiatry at Johns Hopkins University School of Medicine; William A. Neilson, president of Smith College; Dr. Ludvig Hektoen, Dr. Isaac A. Abt and Prof. Charles E. Merriam, Ph.D., of Chicago. The secretary of the committee, Joseph H. Schaffner, 36 South Franklin Street, reported that more than $175,000 had been raised toward the research fund.

Society News.—Dr. Harry A. Singer and Bertha Kaplan, among others, addressed the Chicago Pathological Society at the John Crerar Liberty, April 12, at 8, on "Streptococcus Erysipelatus Toxin-Antitoxin."——The April 23 meeting of the Institute of Medicine of Chicago at the City Club was devoted to the presentation of work by Chicago investigators; there were in all nine papers presented. Dr. B. Brouwer, professor of neurology, University of Amsterdam, gave an address, April 22, under the joint auspices of the institute and the University of Chicago at the Harper Memorial Library on "The Projection of the Retina on the Brain"; Sir Arthur Newsholme, London, England, will lecture at the Harper Library, May 10 and May 11, 4:30 p. m., on "The Present Position of the Tuberculosis Problem" and "The Growth of Social Insurance in Britain."

MASSACHUSETTS

Physician Fined.—Dr. Walter C. Harris, Worcester, was recently fined $500, it is reported, under an indictment charging him with issuing false prescriptions for narcotic drugs and selling narcotics illegally. Dr. Harris paid the fine.

University News.—Dr. Knud Faber, professor of internal medicine, University of Copenhagen, gave an address at the Harvard Medical School, Boston, recently, on "The Intestinal Origin of Pernicious Anemia."

Society News.—Dr. Arthur H. Ruggles, lecturer on psychiatry, Yale University School of Medicine, addressed the Massachusetts Psychiatric Society at the Boston Psychopathic Hospital, March 31, on "Mental Hygiene and the College Student."

Licenses Revoked and Suspended.—Information has been received from the Board of Registration and Medicine of Massachusetts that the registration of Dr. Albert Astrin was revoked by the board, February 11, and that the registration of Dr. Walter C. Harris, Worcester, was suspended for three months from February 11.

Personal.—Dr. Amasa Elliot Paine, Brockton, has resigned from the state service as medical examiner for no. 1 Plymouth District on account of ill health, and Dr. Walter W. Fullerton, Brockton, associate examiner, has been appointed to succeed him.——Dr. Hugh Heaton, New York, and formerly of Boston, has been elected superintendent of the Malden Hospital, Malden.

Sir Arthur Newsholme Gives Cutter Lectures.—Sir Arthur Newsholme, recent principal medical officer of the local government board of England and Wales, will deliver the Cutter lectures on preventive medicine at building E, Harvard Medical School, Boston, April 26-27, 5 p. m., on "The Present Position of the Tuberculosis Problem" and "Remaining Problems in Maternity and Child Welfare." Physicians, medical students and others are cordially invited.

MICHIGAN

Camps for Children.—There were thirty-five camps for boys and girls, sponsored by various organizations in Detroit last summer, which, according to the Child Welfare Committee of the Federation of Women's Clubs, provided outings for 13,085 children, at prices ranging from $4.50 to $12 a week among the camps that charged. There were eleven camps that were free. The outings provided were usually of two weeks duration, but, in addition, the Community Union provided one day outings for 38,365 children. The cost of the camps, not including the one day outings, was $18,274 for 12,297 children, or about $14.85 per child.

Society News.—During March the state medical society conducted postgraduate conferences at Adrian and at Kalamazoo.——Dr. Charles A. Elsberg, New York, addressed the Wayne County Medical Society, recently, on "The Diagnosis of Tumors of the Central Nervous System."——Dr. Charles H. Frazier, John Rhea Barton professor of surgery, University of Pennsylvania School of Medicine, will address the Wayne County Medical Society, April 30, on "Surgical Lesions Originating in the Structures of the Pituitary Body."——Drs. Orla H. Gillett and William R. Vis addressed the Kent County Medical Society, Grand Rapids, April 14, on "Three Case Reports of Shoe-Dye Poisoning," and Dr. L. W. Brown, on "Intravenous Sterile Glycerin Drip in Postpartum Infections." The program was given by the staff of St. Mary's Hospital.

MONTANA

First Baby Clinic.—The state board of health announces that it will establish a permanent free baby clinic this summer in Butte. This will be, it is said, the first of its kind in the state. Dr. Hazel D. Bonness is in charge of the child welfare work in the state.

Personal.—Dr. Paul O. Neraal, Cut Bank, has been elected president of the newly formed Northern Montana Medical Association, which embraces the counties of Teton, Pondera, Liberty, Glacier, and Toole; Dr. Miles D. Riddle, Shelby, is the secretary-treasurer.——Dr. Owen C. Evans, Anaconda, has been appointed health officer of Deer Lodge County.

State Board Meeting.—At the recent annual meeting of the Montana State Board of Health, Dr. Louis H. Fligman, Helena, was elected president; Dr. Byron L. Pampel, Livingston, vice president for the next year, and Dr. William F. Cogswell was reelected executive secretary for a term of four years. In view of the prevalence of virulent smallpox in neighboring states, an order was issued requiring all employees of the board to be vaccinated against smallpox unless they had been vaccinated within the last five years.

NEW JERSEY

Child Guidance in Newark Schools.—A department of child guidance is being organized in the public schools of Newark. There will be a child guidance clinic, which, according to the *Mental Hygiene Bulletin*, will devote most of the time to kindergarten children; but there will be a service for older children who are referred to it. Dr. Bruce B. Robinson, since 1925 assistant director of the Cleveland Child Guidance Clinic, has been appointed director by the board of education. There will be also a chief of social service, a chief psychologist, adequate clerical assistance, and, during the rest of this year, an assistant psychologist and two assistant social workers. The state law requires the examination of certain children who are retarded in school as well as those referred to special classes, and those referred to schools as "incorrigibles." The work will probably develop along visiting-teacher lines, and the children studied will be followed up from year to year.

NEW YORK

New Law for Preventing Rabies.—The governor has signed the Lattin bill; now when the state commissioner of health certifies to a local health officer that rabies is present among dogs in his community, it shall be the duty of the health officer to give public notice, whereupon it shall be unlawful for any dog to be at large unless muzzled until the state commissioner certifies that rabies no longer exists; thus it becomes the duty of all law enforcing officers to cause any dog found at large and not muzzled to be confined, or, if that is not practicable, to be killed; any person killing a dog not muzzled which is known to have bitten a person or animal shall not be held liable for damages, but must report the facts to the local health officer.

Hospital News.—The Mary Immaculate Hospital, Jamaica, L. I., has let contracts amounting to $1,250,000 for new buildings; the hospital eventually will have a bed capacity of 600.——The annual benefit for the tuberculous at Northwood Sanatorium, Saranac Lake, was given at the Manhattan Opera House, New York, April 18. The sanatorium, founded in 1920, has accommodations for twenty-two patients; among the directors are Dr. James A. Miller, Dr. Edward R. Baldwin and Dr. Joseph Brettauer, Saranac Lake; the secretary is Dr. Edgar Mayer, also of Saranac Lake.——The second annual conference of the Hospital Association of New York State will be at the St. George Hotel, Brooklyn, May 27-28; among others, Dr. William A. Jewett of the Kings County Medical Society will discuss "Medical Aspect of the Nursing Situation;" Mr. George F. Sauer, superintendent, Lenox Hill Hospital, New York, "Medical or Nonmedical Anesthetists?" The subject for the afternoon session, May 28, will be "Hospital Care of the Industrial Injured in a General Hospital."

New York City

Research Fellowship.—The Montefiore Hospital for Chronic Diseases announces the establishment of the Hilda Stich Stroock Research Fellowship, with an honorarium of $1,200 a year. The fellowship may be taken in the medical, neurologic, tuberculosis or cancer divisions. Applications should be sent to the medical director of the hospital, Gun Hill Road, New York City, with a brief account of previous training, letters of recommendation, and a general plan of the work contemplated.

Society News.—Dr. John M. Wheeler has been elected president of the New York Ophthalmological Society for 1926; Dr. Francis W. Shine, vice president, and Dr. John H. Dunnington, secretary-treasurer.——Dr. Howard V. Merrell was elected president of the Flatbush Medical Society, April 9, succeeding Dr. Stanley B. Thomas; Dr. Harry H. Patrie was elected secretary.——About a thousand persons attended the sixth annual banquet, April 10, of the Italian Medical Society of Brooklyn, under the presidency of Dr. Paul C. Fleri; the vice president, Dr. Francis Caponegro, was toastmaster. Among the speakers were Dr. O. Paul Humpstone, president, Kings County Medical Society; Dr. Giuseppe Previtali, president, Associated Italian Physicians in America; Dr. Walter A. Sherwood, president, Associated Physicians of Long Island, and Dr. John S. Read, of the Long Island College Hospital.——Dr. George de Schweinitz, Philadelphia, formerly president of the American Medical Association, was invited to take part in the discussion at the stated meeting of the New York Academy of Medicine, April 15, when Dr. Walter D. Sheldon, Mayo Clinic, Rochester, Minn., spoke on "The Diagnostic Significance of Visual Field Changes in the Localization of Brain Tumor," and Dr. Ward A. Holden on "Papilledema and Papillitis."

NORTH CAROLINA

Superintendent Appointed.—Dr. John Donnelly, Charlotte, has been appointed superintendent of the new Mecklenburg County Tuberculosis Sanatorium, which will open, June 1. Dr. Donnelly served during the World War with the tuberculosis unit of the eightieth division, and for years has been in charge of the tuberculosis work of Charlotte and Mecklenburg county.

Hospital News.—Dr. Lester A. Crowell, Lincolnton, has been made president of the new Caldwell Hospital Company. The company has secured the property of the former Lincolnton Hospital, which will be remodeled and enlarged. Dr. Robert W. Petrie, Charlotte, secretary, will assume the direction of the hospital about June 1; among the directors are Drs. William F. Elliott and Gordon B. Crowell.

PENNSYLVANIA

Society News.—Dr. Arthur C. Morgan, professor of applied therapeutics, Temple University Medical School, Philadelphia, addressed the Lancaster City and County Medical Society, April 7, on "Symptoms of Diagnostic Value."——Dr. Elmer H. Funk, assistant professor of medicine, Jefferson Medical College, addressed the Berks County Medical Society, April 13, on "The Diagnosis and Treatment of Pneumonia."——The Westmoreland County Medical Society will hold its fifth annual clinic and banquet at the Country Club, Greensburg, May 6, to which the adjacent county medical societies are cordially invited. The clinics will be held by Drs. Elliott P. Joslin and Frank H. Lahey, both of Boston.——Dr. Joseph V. Klauder addressed the Lehigh County Medical Society, Allentown, March 9, on "Common Skin Diseases."

Personal.—Mr. Joseph Noh, a member of the faculty of Purdue University, Lafayette, Ind., has been appointed full-time secretary of the Pennsylvania Pharmaceutical Association with headquarters in Harrisburg.——Dr. Rush E. Castelaw has resigned as medical superintendent of the Williamsport Hospital, Williamsport.——Dr. Mahlon B. Ballard, Troy, has been appointed county medical director for Bradford County.——Dr. John W. Wright, Erie, resigned April 1, as attending physician to State Tuberculosis Clinic no. 3, after having been connected with the state department of health in this capacity for nineteen years; Dr. Katharine H. Law Wright has been appointed as his successor.——Dr. Herbert H. Holderman has been appointed surgeon-in-chief of the Locust Mountain Hospital at Shenandoah, which will be opened soon. The hospital was started under private auspices, but during the past year has been taken over by the state welfare department. Dr. Holderman is a native of Shenandoah.

Philadelphia

Personal.—Dr. Myron A. Zacks has been appointed chief of the department of otolaryngology at the Northwestern General Hospital.——A testimonial dinner was tendered Dr. Albert P. Brubaker at the Adelphi Hotel, March 27, by the alumni of the Philadelphia College of Dental Surgery and the Dental Department of Temple University, of which Dr. Brubaker has been professor of physiology for more than twenty years.

Society News.—Francis G. Benedict, Sc.D., director of the nutrition laboratory, Carnegie Institution of Washington, Boston, addressed the Physiological Society of Philadelphia, March 15, on "Perspiratio Insensibilis: Its Significance in Physiology and Pathology and Its Relationship to Skin Temperature and Heat Loss."——Dr. Charles G. Kerley, New York, addressed the Philadelphia Pediatric Society, April 13, on "Roentgen-Ray Demonstration of Gastro-Intestinal Abnormalities, with Symptomatology and Treatment."

Philadelphia County Medical Society.—A drive for an endowment fund of $250,000 will be started by this society within a few weeks, the president, Dr. Moses Behrend, announces, to provide for an adequate library and postgraduate courses for members, one of which will be for instruction in making periodic physical examinations, and another to bring up to date the knowledge of practitioners who have been out of schools for years. The new building of the society was formally dedicated, April 20-21.

RHODE ISLAND

Health at Providence.—Telegraphic reports to the department of commerce from sixty-eight cities with a total population of twenty-nine million, for the week ending April 3, shows that the highest mortality rate (30.4) was in Providence, and that the rate for the group of cities was 17.7. The mortality rate for Providence for the corresponding week last year was 16, and for the group as a whole, 14.7.

SOUTH CAROLINA

University News.—A campaign is in progress to raise an endowment fund for the Medical College of the State of South Carolina under the chairmanship of Dr. D. Lesesne Smith, Spartanburg. An organization will be formed in every county in the state. Letters have been sent to every graduate of the state medical school, requesting their cooperation.

Collaborating Epidemiologists.—The secretary of the state board of health announces that fourteen collaborating epidemiologists were appointed recently to assist the U. S. Public Health Service and the state health department in securing accurate reports of communicable diseases in South Carolina. The appointees are members of county health units; local physicians will report communicable diseases to them in their districts; they will in turn forward a summary to the state board of health, which will then forward a summary to the U. S. Public Health Service. Among the collaborating epidemiologists appointed are:

Dr. Erin E. Epting, Anderson.
Dr. Leon Banov, Charleston.
Dr. Wallace L. Poole, Gaffney.
Dr. Archie B. Hooton, Darlington.
Dr. Henry G. Callison, Newberry.
Dr. Grover C. Bolin, Orangeburg.

SOUTH DAKOTA

Meeting of Health Officers.—The superintendent of the state board of health, Dr. John F. D. Cook, has called a meeting of all county and city health officers of the state to be held at Aberdeen, May 18, preceding the annual meeting of the state medical association in that city; among the speakers will be Dr. George M. Boteler, director of the Brown County Health Department, whose subject will be "County and City Organization"; Dr. Merrill W. Pangburn, director, Pennington County Health Department, "Goiter Survey"; Dr. Rodell C. Warne, superintendent, Davison County Board of Health, "Communicable Disease Control"; Dr. Francis E. Bouza, superintendent, Mellette County Board of Health, "Moses, the Premier Health Officer," and Dr. Joseph C. Waterman, superintendent, Gregory County Board of Health, "Organization of County Health Officers."

UTAH

Society News.—A ten story medical arts building for the exclusive use of the medical and allied professions is being erected at Salt Lake City.——The Salt Lake County Medical Society devoted its February meeting to medicomilitary matters; the program for the March meeting of the society was arranged by the Utah Ophthalmological Society.

State Medical Meeting.—The Utah State Medical Association will hold its annual meeting at Salt Lake City, May 6-8. The house of delegates will meet each day at 12 o'clock; the banquet will be at 8 o'clock at the Hotel Utah, Friday evening. Among the visiting speakers will be Dr. Harry Gideon Wells, professor of pathology and chairman of the department, University of Chicago, and Dr. Anton J. Carlson, professor of physiology and chairman of the department, University of Chicago.

GENERAL

Examination in Otolaryngology.—In addition to the examination held at Dallas, Texas, April 19, and San Francisco, April 27, the American Board of Otolaryngology will hold an examination at the Royal Victoria Hospital, Montreal, June 1. Information may be secured from the secretary, Dr. Hanau W. Loeb, 1402 South Grand Boulevard, St. Louis.

Automobile Fatalities.—During the four weeks ending March 27, the total number of automobile fatalities in seventy-nine large cities in the United States reported to the department of commerce was 348. Fifteen of the cities showed no automobile fatalities during this period, while New Bedford and Waterbury have reported no fatalities during the last twelve weeks.

Society News.—The Central Tri-State Medical Association will meet in Huntington, W. Va., May 6; Dr. George W. Crile, Cleveland, will speak on "Certain Problems in the Treatment of Diseases of the Thyroid Gland with Special Reference to Hyperthyroidism"; Dr. John A. Kolmer, Philadelphia, on "The Pathology and Immunity of Syphilis in Relation to Serum Diagnosis and Treatment"; Dr. Stewart R. Roberts, Atlanta, "The Heart Muscle," and Dr. Hugh Cabot, Ann Arbor, Mich., "The Present Status of the Treatment of Prostatic Obstruction."

Study of Tumors of Lymph Nodes.—The American Association of Pathologists and Bacteriologists has inaugurated a "registry" for the study of primary tumors of the lymphatic system, and has appointed a commission comprising Dr. James Ewing, New York, and Dr. Frank B. Mallory, Boston. Major James F. Coupal, Medical Corps, U. S. Army, will collect gross and microscopic material, histories and other information. The cases will be referred to various investigators for opinion, and, ultimately, collated. The association has decided to announce each year a field of work that would be especially welcome on the program of the following year; at the annual meeting, April 2, Dr. Hans Zinsser, Boston, was elected president; Dr. James W. Jobling, New York, vice president; Dr. Frank B. Mallory, Boston, treasurer, and Dr. Howard T. Karsner, secretary, 2109 Adelbert Road, Cleveland.

Conference on Medicinal Wines.—Gen. Lincoln C. Andrews, federal prohibition administrator, held a conference, April 8, with about thirty-five representatives of organizations interested in the distribution of medicinal wines. The conference was called by Mr. H. K. Weeks, recently appointed federal supervisor of wine control, and was the first meeting to be held by prohibition officers with representatives of manufacturers and distributors of medicinal wines. Among others, Dr. William C. Woodward, Chicago, representing the American Medical Association, attended the conference. Although treasury department officers would not disclose the prospective plans, it is understood that General Andrews may consider lifting the present regulations which prohibit the importation of wines for medicinal purposes, but that no further extension of existing regulations in the issuing of wine prescriptions will be allowed.

Information Wanted on Effects of Gas Warfare.—The board of physicians recently appointed by the director of the U. S. Veterans' Bureau to study the residual effects of war gases (The Journal, March 20, p. 882) desires the cooperation of physicians. The board will welcome first-hand opinions and reprints of any article which a physician may have written on the subject; also contributions from personal experience. Information is particularly desired on the following points:

1. Does any war gassing received in action result in disability which is relatively lasting and permanent?
2. Does it cause lasting anatomic (pathologic) changes, with or without disturbance of function (symptoms and disability)?
3. What organs or systems may thus be permanently affected or disturbed?
4. What symptomatology may exist under these circumstances?
5. If war gassing does produce relatively permanent effects, may a similar condition or conditions be produced by other agencies (diseases such as influenza, tuberculosis or effort syndrome)?

American Health Congress.—Among the joint sessions that will characterize the American Health Congress, Atlantic City, May 17-22, will be a joint session of the American Child Health Association, the American Public Health Association, the National Organization for Public Health Nursing and Conference for State and Provincial Health Authorities of North America, which will discuss public health administration of communities. Three plans for the health administration of cities will be described by men who have developed them; a fourth health plan for the county health organization will be presented. Many other member organizations of the National Health Council will participate in the congress, and in addition to sectional medical and joint sessions there will be four general sessions. Some of the speakers will be Sir Arthur Newsholme, "Relative Values in Public Health Work"; Prof. C.-E. A. Winslow, "Whose Responsibility Is Public Health?" Dr. Ray Lyman Wilbur, "Is Public Health Improving the Race?" and George E. Vincent, Ph.D., and Dr. Alice Hamilton, "International Health Work." Mr. Herbert Hoover will give the opening address for the American Child Health Association.

FOREIGN

American Hospitals Closed.—It is reported from London that two large American hospitals in South China have been closed on account of activities of the "Red labor unions". The Canton Hospital, operated by the American Presbyterian Mission, was blockaded by the unions, and food and electric supplies shut off. The American Hospital at Wuchow was also compelled to close; its medical staff left on board an American gunboat.

Health in Palestine.—There were only two deaths from malaria last year in Jerusalem, against 113 deaths in the last nine months of the preceding year. The League of Nations Non-Partisan Association says that pilgrims to Palestine must undergo inspection for malaria before entering the Holy Land, and that a malaria quarantine has been ordered on the Hedjaz and Sinai railways because of the crowds of Moslems, Christians and Jews entering and leaving Palestine annually. The decreased malaria infection has been brought about partly through the draining of swamps and the conversion of coastal plains into lands suitable for cultivation, partly by a war on mosquitoes for six years, which has prevented fresh infections in all of the towns except Haifa, and partly by constant surveillance of the children in the public schools. Trachoma has been reduced among Jewish school children from 35.4 per cent in 1920 to 10.5 per cent in 1925. Smallpox is well under control. Typhus is only sporadic; bubonic plague has been greatly reduced by the rat-proofing of houses and other measures, and no case was reported in Palestine in 1925. Measles, tuberculosis and chickenpox, however, were serious health problems: there were 1,232 deaths from measles among 6,936 cases. Other diseases noted to a great extent in the latest epidemiologic report of the League of Nations are influenza, epidemic ulcer, leprosy and pneumonia. The birth rate noted was 51.3 per thousand, or an increase of about 4 per cent over the previous year. The infant mortality was 184.8 per thousand births. The settled population of Palestine is estimated in the report as 681,245, of which number 95,000 are Jews, 505,000 Moslems and 74,000 Christians; about 103,331 Bedouins wander here and there. The league obtained most of its facts from the annual report of the department of health of Palestine.

Deaths in Other Countries

Dr. A. Haegler, Basel, ex-president of the Swiss Medical Association, aged 62, of cancer of the rectum.——**Dr. F. Dimmer**, professor of ophthalmology, Vienna, the pioneer in photography of the fundus of the eye, and author of a classic work on the ophthalmoscope in 1921, aged 71.——**Dr. M. A. van Keerberghen**, Brussels, one of the founders of the Brabant Medical Society, killed in an automobile accident, aged 70.——**Dr. W. Permewan**, formerly lecturer in laryngology, University of Liverpool, March 9, aged 60.——**Dr. G. Gradenigo**, professor of otorhinolaryngology, Naples, founder and editor of the *Archivio di Otologia, Rinologia e Laringologia*, now in its thirty-seventh volume, and president of the Italian specialist society.——**Dr. J. Kyrle**, professor of dermatology and syphilis, Vienna, editor of the *Wiener klinische Wochenschrift*.——**Dr. P. Bunge**, emeritus professor of ophthalmology, Halle, aged 73.——**Dr. Zoege von Manteuffel**, emeritus professor of surgery, Dorpat.——**Dr. Tous y Biaggi**, editor of the *Revista Española de Medicina y Cirugía*, Barcelona.——**Drs. Maisel, Meiltscharski and Hirschfeld**, connected with a private clinic at Moscow, were shot by a former patient because they had been unable to cure him. The assailant killed himself also.——The death is reported of **Dr. Levy**, assistant professor of physiology, Turin. She was with a skiing party overwhelmed by an avalanche.

The Problem of the Intoxicated Motor Driver

The "True Temperance Scientific Committee," which consists of a number of physicians and others interested in the problem of alcohol who take up an antiprohibition attitude, has issued a useful pamphlet on the difficult current question of the intoxicated motor driver. The committee insists that the word "drunk" is not enough to signify an offense and thinks that legislators should abandon its use. "Simple drunkenness" (to adopt the phraseology of the licensing statistics) should not be a legal offense at all; it is not the drunkenness that matters to the law; it is the nuisance or harm to the public committed by a person in a state of absence of self-control with which the law is properly concerned. If he is incapable on the public highway, it is the business of the police to look after him not because of his drunkenness but because of incapacity and the consequent danger to himself, and possibly to others. If he is disorderly, he must be taken in hand for the public nuisance of his disorderliness, whether due to drunkenness or another cause. If he is steering a car in a zigzag course along the highway, it is his loss of controlling power over a dangerous vehicle on which the attention of the law should be fixed. When the criminal justice bill was going through the house of commons, an effort was made to get rid of the word "drunk." The effort failed, because the substituted words proposed were "in a state of intoxication whereby his capacity to act is impaired." Those words, the committee considers, were not the best. The committee would not really carry the matter further than the present dual "drunk and incapable." It is not enough to say "any person who is drunk in charge on any highway or other public place of any mechanically propelled vehicle," or who is "in a state of intoxication whereby his capacity to act is impaired"; the act should read, "any person who is in charge, etc., while in a condition which prevents him from exercising adequate control of the vehicle," or words to a like effect. Then the evidence would properly be concentrated on the signs of the lack or presence of control, and such evidence would be apparently easier and more satisfactory from any witness, and would be to the point. Obviously, it would mean setting a higher and different standard of sobriety for motorists as compared with pedestrians; but that is only right: a collision with a pedestrian has not the consequence of a collision with a motor car. Meanwhile, and until the law is made more explicit, it should be possible for magistrates to give varying meanings to the word "drunk" according to the varying collocation. A word in a statute is interpreted with reference to its subject matter; it should not be an undue extension of that principle to interpret the word "drunk" (admittedly an often vague term) in accordance with the matter of the charge, and give it a different meaning when used of a person in charge of a motor car from that applicable to a pedestrian or to a mere passenger in a motor car. It is suggested that a statute should condemn a person in charge of a motor car "while in a condition which prevents him from exercising adequate control"; and this phrase should apply to others than those whose condition is the result of too much alcohol. A man may be in such a condition from various causes—nervous disease, for example. But the result on the victim of his bad driving is the same. Then, however, the innocent sufferer would be punished. Punishment, as we view it today, is intended to be remedial, not vindictive, and here is particularly a case in which what the public wants is a remedy against the danger of bad driving. The most direct method of obtaining this protection is not by fines and imprisonment but by stopping a man liable to be unfit to drive from driving. The taking away or suspension of the license is therefore the best remedy. That can be applied without injustice to the man whose helpless condition arises from disease not of his own making as well as to him whose incapacity comes from drink. One has no more right to drive than the other.

The Proposed Separate Medical Register for the Irish Free State

The *Irish Times* publishes proposals which were submitted to a subcommittee of physicians last December by the president of the Royal College of Surgeons in Ireland, with a view to a settlement of the controversy concerning the establishment of a separate medical register and the consequent isolation of Free State physicians from the general medical council (described in previous letters). The proposals, which were submitted afterward to the Free State government in a modified form, were as follows: "In order to give effect to the wishes of the Saorstat government to control the registration and the discipline of medical practitioners in the Saorstat, and at the same time to preserve the educational advantages and the world-wide status given by the partnership in the general medical council, the following procedure is suggested: 1. Renew the partnership in the general medical council until such times as either the government of the Saorstat or of England may apply for a termination of such partnership. 2. (*a*) The government of the Saorstat to set up a medical register for the Saorstat and a medical council to supervise and control such register; (*b*) direct the Saorstat medical council that any person of good repute who holds a medical degree or qualification from a university or college, etc., which is recognized by the Saorstat medical council shall be eligible for entry on the Saorstat medical register; (*c*) direct the Saorstat medical council that, in addition to the universities and colleges, etc., which may be recognized by the Saorstat medical council, any university or college, etc., which may be recognized from time to time by the general medical council shall be recognized by the Saorstat medical council; (*d*) any citizen of the Saorstat who may wish to practice in the Saorstat must have his name on the Saorstat medical register; (*e*) any person who is not a citizen of the Saorstat shall be debarred from practicing in the Saorstat unless his name is on the Saorstat medical register or on some section of the general medical register." When the amended proposals were submitted to Mr. Cosgrave and Mr. P. McGilligan, minister for industry and commerce, they were received sympathetically, but long delays have followed, and the present position is obscure. The government has passed an act extending the existing arrangements with the general medical council until August 1, and it is hoped that before that date a permanent settlement will have been reached. For the moment, negotiations between the physicians and the government seem to be at a standstill.

Local Insurance and Emigration

The question raised in the house of commons last year as to whether schemes of social insurance act as a deterrent to emigration has been investigated by an interdepartment committee. The report presented to the secretary for the dominions gives the two chief causes which tend at present to discourage emigration as bad trade conditions and the restrictions placed by the dominion authorities on the granting of assisted passages. The cumulative effect of the various schemes of social insurance is considered to be a subsidiary cause. "These schemes," says the report, "have an effect in discouraging migration, both directly as a result of the sense of security they induce and indirectly in that they raise the standards of living and so counteract to an appreciable extent the attraction of the life of independence offered in the dominions." The national health insurance scheme is not considered to act perceptibly as a check on migration. Unemployment insurance and the comparatively recent extension of outdoor poor law relief to able-bodied persons are considered to discourage migration to an appreciable extent at precisely those ages when, other thing being equal, it might be expected that the opportunities of oversea life would prove most attractive. Old age pensions are not regarded as having much effect on migration, and the effect of the widows' and orphans' pension scheme, it is stated, must largely be a matter of conjecture at this early stage of its operation. It is considered, however, that this scheme will have some influence in the case of married men, who will naturally take into account the loss, on migration, of the provision made for dependents under the scheme, and that the scheme will be a material factor in the case of widows contemplating migration. The view is taken that when openings in the dominions are more varied and attractive, when bolder and more comprehensive schemes of settlement are undertaken, and if the present restrictions on assisted migration can be modified and more opportunities provided for the oversea settlement of families and women, social insurance schemes will have comparatively little effect. The committee recommends that the general question of the standardization of schemes of social insurance throughout the empire should be considered by the imperial conference; that the attention of the committee on the administration of the unemployment insurance acts should be drawn to the attitude toward migration of persons approaching 18 and for a few years thereafter; that a year's pension should be paid on migration to persons drawing pensions under the widows' and orphans' and old age contributory pensions schemes; that the cost of medical examination of applicants for assisted passages who are insured under the national health insurance scheme should be paid under that scheme; that greater publicity should be given to the social insurance schemes that exist in the dominions, and that extended facilities should be provided for training juveniles in the elements of rural occupations.

JAPAN

(From Our Regular Correspondent)

March 16, 1926.

A Rare Medical Book

In the earthquake in Tokyo in 1923, a rare Dutch medical book, Kulm's "Tabula Anatomica," was destroyed. The old volume was the property of Prof. Dr. Matao Nagayo, director and professor in the Tokyo Imperial University. Nearly 150 years ago, in the Tokugawa era, the book was brought to Japan by a Dutch missionary. At that time people here knew very little about European medical science. It was therefore quite an epoch-making event in the medical history of Japan when Dr. Gempaku Sugita and his friends, earnest students of Dutch medical science, went to the postmortem of a criminal held at Kozuka Common, one of the execution grounds, in the suburbs of Edo (now Tokyo) and there studied anatomy, marveling at the exactness of the illustrations in the foreign book. Dr. Gempaku's account of his difficulty in translating the book, with his poor knowledge of Dutch, is related in his autobiography entitled "Rangaku Kotohajime" (Pioneering in Dutch Science). His "Kaibo Shinsho" (New Anatomy) was the first translation in Japanese. A century elapsed, and Dr. Sensai Nagayo, father of Professor Nagayo, happened to get possession of the original book of "Kaibo Shinsho." He valued it more highly than any other book in his library and would not part with it, though he sent it to an exhibition in Dresden and another time displayed it in the Far East Tropical Medicine Congress held in Java. Great was his son's sorrow when the heirloom was burned in the earthquake disaster. But his joy was even greater when he received another copy of "Tabula Anatomica," the gift of the Dutch medical scholar M. Van Roemer, ex-naval surgeon, of Java. He has written to Professor Nagayo that he was unable to attend the Far East Tropical Medicine Congress held in Japan last autumn, and that he sent the book to promote friendly relations between Japan and his country. In his letter of thanks the professor said that his joy was as if one's dead child had come to life again. He took the volume to the annual memorial service of dead medical sages held at Kozuka Common to show it to his friends. It is reported that after consulting with Drs. Kitasato and Miyakawa he has decided to donate the invaluable book, rare even in Holland, to the new library of the Tokyo Imperial University, now in course of reconstruction.

Lepers

According to the census taken Nov. 16, 1925, by order of the department of home affairs, the number of lepers in Japan amounts to 15,400. This shows a decrease of 861 compared with the investigation of March, 1919.

Menstruation of Students

Dr. Takao Hosaka, following an investigation of about 100 healthy students in the Tokyo Girls' Dental College, reports that the average age of the first menses is about 14½ years. About 17 per cent of them had no knowledge of menstruation before its onset in themselves. Some 60 per cent had been told about it by teachers or friends, and about 13 per cent, by their mothers or elder sisters. Their first experiences of it aroused various emotions: "wonder" and "terror," accompanied by "uneasiness"; though about 8 per cent were pleased that they had grown to adulthood. About 7 per cent thought nothing of it in particular. The average course is about five days; in some cases four days, and in others, three days. In only three girls was the duration more than a week. As to the period between menses, forty-two girls are of "retrogressive nature" (twenty-eight days), while thirty-nine are of "progressive nature" (more than thirty days). More than half of the girls complained of "uneasiness" in the lower abdomen; about a quarter of them of "pain" in the lower abdomen or loin; sixteen, of "weariness," "drowsiness" of "poor appetite"; and three felt refreshed.

Japanese Practitioners in North Sakhalin and Siberia

At the Moskva meeting of the oil field committee, concerned with the North Sakhalin treaties, it was decided that half of the laborers in the oil fields of North Sakhalin should be Russians and half Japanese, and that Japanese physicians might be engaged to attend the laborers. It was also agreed that resident Russians who are not oil field laborers may consult Japanese physicians, and that medical certificates and necropsy certificates of these physicians will be acknowledged there. Attending of Russians who are not oil field laborers will be subject to certain regulations. The arrangements are said to have been made by Rear Admiral Kumagawa of the Japanese committee, and one member of the Russian committee. Japanese physicians were permitted to practice in Siberia almost without restrictions toward the end of the monarchical days, but under the soviet régime this is prohibited. Many wish to regain the former privilege, and one of the Japanese authorities expresses his private opinion that a permanent treaty of reciprocity between the two governments should cover this matter.

Improvement of the Electrocardiogram

Mr. Toyoya Yasuhara, director of the clinical laboratory in Osaka, is one of several who have been devoting themselves to improving the electrocardiograph. The merits of Mr. Yasuhara's newly designed apparatus are said to be that it is simple enough to be handled even by a nurse, and that it can draw curves on white paper in Japanese ink, rendering the trouble of photographing unnecessary.

Tattooing of Female Ainus

Dr. Kamataro Nakajima of the Medical College of the Hokkaido Imperial University has made investigations of the tattooing of Ainu women in the tribe called Kamikawa Ainu. This tribe, now settled in Chikabumi, Asahikawa, Hokkaido, consists of sixty houses and more than 280 natives. Dr. Nakajima found fifty-four tattooed women among 148 female Ainus. The Ainus had a superstition that women had much bad blood in their bodies and had to be tattooed in order to be bled and made strong and healthy. They also practiced tattooing as a form of therapeutics and preventive medicine. Adopting the same method as the Melanesian race, the tattooing was begun around the mouth when a girl became 9 years of age. It was later extended as far as each forearm. At last it was completed on the back of each hand by the time she attained her marriageable age of 15 or 16 years. Parents would force such a painful practice on their daughter, for a girl whose tattooing was complete was regarded as qualified for marriage as an adult. Moreover, it may be presumed that with them tattooing was a symbol of beauty and exerted a sexual attraction. Now nobody below the age of 28 is found tattooed. The custom has fallen into disuse since they have come in contact with the Yamato race (pure Japanese)

Public Health Congress

The third Brazilian Congress of Hygiene will be opened at São Paulo, September 28. Preparations are so far advanced that the meeting will surely be as successful as those held at Rio de Janeiro and Bello Horizonte. The following subjects have been suggested for discussion by different agencies which will be represented at the congress; such as the national department of public health, the Rockefeller Foundation, local health departments, Oswaldo Cruz Institute, and the Brazilian Public Health Society: epidemiologic rôle of flies; water purification; home prevention of malaria; worm infestation index; epidemiology and prophylaxis of malaria in Brazil; permanent organization of local health departments; epidemiology and prophylaxis of typhoid fever; prevention of leprosy; effect of sanitary works on public health; work accomplished in Brazil in protecting milk supplies; infant hygiene.

Myopathy with Heart Changes

Dr. Pires recently exhibited before the Society of Neurology, Psychiatry and Legal Medicine a patient with atrophy of the muscles in the chest, shoulder and arm, as well as in the abdomen and lumbosacral region. Lordosis was quite marked. The flattening of the sternum caused a sort of shoemaker's chest. The disease was undoubtedly a form of Erb's juvenile type. The personal and familial history proved immaterial, the condition dating from as far back as the patient could remember. A study of the cardiovascular system by Dr. P. da Cunha showed interference with the deep thoracic blood flow; upper costal breathing with the aid of auxiliary muscles; displacement of the heart toward the abdominal cavity; enormous enlargement of the heart; diaphragm, almost motionless. The myopathy has apparently entailed changes in the myocardium. A number of similar cases have already been confirmed in the necropsy, abroad by Marinesco and A. Leri and here by da Cunha himself, who described several in his professorial thesis.

Honors to Couto

As stated in a previous letter, Dr. Couto, the president of the National Academy of Medicine and a professor in the Rio de Janeiro medical school, is now touring Europe. The lecture he delivered before the Berlin Medical Society was attended by high government officials as well as the most prominent German scientists. His lecture dealt with cardiac changes noted during the treatment of malaria, yellow fever, beriberi and Chagas' disease. Even the newspapers commented favorably on the visit. In his presentation speech, Geheimrat Goldscheider recalled that Couto had been one of the first in starting, after the war, a subscription to enable German scientists to continue their research work. During his stay in Germany, Couto will be a guest of the department of foreign affairs. The president of the republic, Marshal von Hindenburg, received the Brazilian professor at a private audience.

Duodenal Drainage

Prof. O. de Oliveira described before the Academy of Medicine some experiments and clinical trials of duodenal drainage as developed by Einhorn, Meltzer and Lyon, and now set forth in a thesis by Dr. Thibau, Jr., of Oliveira's clinic. The experiments were made under Oliveira's supervision by Thibau, with the assistance of Dr. Figueiredo Vasconcellos, chief of the laboratory. Thibau has improved the technic, and his suggestion as to the introduction of the tube by the nose obviates some difficulties so far encountered. As relates to diseases of the pancreas, Thibau's original experiments show the influence of splenic juice on the enzymatic potency of the duodenal content, thus confirming previous uncertain clinical data. According to Oliveira duodenal drainage is a great help in diagnosis, can solve many pathologic problems, and may render much assistance in treatment, especially in diseases of the gallbladder and gall ducts.

The Physicians of Germany in 1925

In an article in the *Deutsche medizinische Wochenschrift,* the medical statistician Prinzing discusses the distribution of German physicians in 1925. It appears from the article that the number of physicians in Germany, inclusive of the Saar region, in 1925 was 41,650. According to the census of June 16, 1925, the population of Germany was 62,478,872, which would indicate 6.67 physicians to 10,000 inhabitants. This shows an increase over the record of 1901 of more than 33 per cent, and over that of 1913 of 30.5 per cent. For purposes of comparison, the relations of physicians to population are given for a number of pivotal years in table 1.

Table 1.—*Number of Physicians per Ten Thousand Inhabitants in Germany*

Years	No. of Physicians	Years	No. of Physicians
1901	4.92	1913	5.11
1905	5.08	1921	5 99
1911	5.02	1925	6 67

The absolute increase, as compared with 1921, was about 5,400. It cannot be ascertained exactly, since in the census of 1921 the ceded portions of Schleswig-Holstein and Upper Silesia were included, while the physicians of the Saar region were omitted.

Table 2 shows the number of physicians in the various German states in 1911 and in 1925. However, in some provinces of Prussia there have been a good many changes. The Saar region is included in the Rhine province.

Leaving out of consideration the chief urban centers, the states with the highest percentage of physicians were, in 1925, Hesse-Nassau, Hesse, Baden and Waldeck, all of which have had, for many years, a large number of physicians. Hesse-Nassau, with its 2,400,000 population, has the large cities Frankfort-on-the-Main and Cassel, three important health resorts (Wiesbaden, Homburg, Ems) and the University of Marburg, in all of which there are many physicians. In the state of Hesse, 17.7 per cent of the physicians live in Giessen and Nauheim. In Baden, the number of physicians is increased by the two universities of Freiburg (im Breisgau) and Heidelberg and the health resort of Baden-Baden. Waldeck owes its high percentage of physicians to the health resort at Wildungen. In West Prussia-Posen, the large number of physicians is doubtless partly due to emigration from the ceded districts.

Table 2.—*Number of Physicians to Ten Thousand Inhabitants in the Various German States, Etc.*

	Number of Physicians to 10,000 Inhabitants 1911	Number of Physicians to 10,000 Inhabitants 1925	Percentage of Increase
East Prussia	3.39	4.42	30
Greater Berlin	10.90	13.40	23
Brandenburg	4.04	5.00	24
Pomerania	3.81	4.92	29
West Prussia-Posen	.....	7.51	..
Silesia	3.87	5.19	34
Saxony	4.55	5.86	29
Schleswig-Holstein	5.28	6.37	21
Hanover	4.01	6.05	23
Westphalia	3 75	5.14	37
Hesse-Nassau	7.14	8.54	20
Rhine Province	4.96	5.83	18
	3.24	4.71	45
	4.97	6.48	30
Bavaria	5.31	7.03	32
Saxony	4 84	5.75	19
Wurttemberg	4.42	5.91	34
Baden	6.03	7.38	22
Thuringia	4.49	5.74	28
Hesse	5.95	7.94	33
Mecklenburg (the two states)	4.74	6.36	31
Oldenburg	3.61	4.80	33
Brunswick	5.64	6.95	23
Anhalt	4.38	5.55	27
Lippe	3.70	5.83	58
Waldeck	8.91	7.50	..
Hamburg	7.45	10 38	39
Bremen	7.63	9.75	28
Lübeck	7.12	9.96	40

Table 3.—*The Number of Physicians in Cities of Various Size in 1925*

Cities, Towns and Communes	Number of Inhabitants	Actual Number of Physicians	Number of Physicians per 10,000 Population (1925)	Number of Physicians per 10,000 Population (1911)
Communes, under 10,000 pop.	35,019,100	13,323	3.80	2.7
Cities, 10,000-20,000 pop.	3,529,586	2,543	7.20	6.4
Cities, 20,000-50,000 pop.	4,527,529	4,268	9.43	
Cities, 50,000-100,000 pop.	2,879,167	2,995	10.40	8.6
Cities (46) with more than 100,000 population	16,519,490	18,521	11.21	9.6
Germany as a whole	62,474,872	41,650	6.67	5.0

The variations in other parts of the country are due mainly to the mode of distribution of the population among the towns, large cities and rural districts. The Rhine Province and Westphalia, however, in spite of the great number of large and medium-sized cities, have a low percentage of physicians. This is due to the facts that in these states medical treatment is largely in the hands of physicians engaged by miners' unions, and that a large number of workmen are delegated to each physician. According to an enumeration in twenty-nine cities in the industrial district comprising portions of the Rhine Province and Westphalia in the report of the League of German Assistant Physicians, and covering a population of 2,700,000, there were 5.3 physicians to 10,000 inhabitants, whereas, in German cities with more than 10,000 inhabitants, the proportion of physicians was 10.32.

A comparison of the number of physicans in cities of various size, as recorded in 1925, is given in table 3.

The increase in the number of physicians in towns with less than 10,000 inhabitants furnishes evidence that the rural sections are better provided for than formerly. The old complaint that young physicians were reluctant to settle down in rural communities can no longer be advanced. If the new list of physicians is compared with the prewar list, it will be noted that there are now physicians in many rural communities in which there were none before the war.

Table 4 gives a comparative view of the number of physicians per 10,000 inhabitants in the eleven cities of Germany with more than 400,000 inhabitants, arranged in diminishing order of population.

Table 4.—*Number of Physicians per Ten Thousand Inhabitants in the Eleven Cities of Germany with More Than Four Hundred Thousand Population*

Cities in Diminishing Order of Population	1901	1911	1925
Greater Berlin	11.7	10.9	13.4
Hamburg	8.1	7.6	10.7
Cologne	9.5	10.5	10.2
Munich	14.1	16.5	22.0
Leipzig	9.9	8.8	8.3
Dresden	11.2	9.4	10.8
Breslau	12.7	11.6	14.0
Essen	6.2	4.7	4.8
Frankfort-on-the-Main	12.0	11.6	14.8
Düsseldorf	8.0	8.1	10.2
Hanover	11.5	10.4	9.6

The decrease shown in the proportion of physicians in a few cities is, in a sense, only apparent, and is due to the fact that suburbs with fewer physicians than the more central districts have been annexed. The proportion of physicians in Munich is especially high, owing to the large number of physicians on the medical faculty of the University of Munich. That factor plays a bigger part in a city of the size of Munich than it does in Greater Berlin, which is almost six times as large. The proportion of physicians in Essen is small because, among the 220 resident physicians, there are forty-one who are engaged by miners' unions.

Health Week

With a view to enlighten the population of Germany on hygienic subjects, a health week has been set apart which will be celebrated throughout the country. The campaign will be carried on by means of lectures, exhibits, motion pictures and the like, which will be aided by physicians and heads of health insurance societies. The preparations for the event will be in the hands of a large committee, of which Professor Hamel of the federal ministry of the interior will be chairman. Subcommittees have been appointed to serve in the several states. In Berlin, seventy-two public lectures, illustrated by lantern slides and motion pictures, will deal chiefly with the protection of juveniles, children and the unborn child. Outdoor entertainments will accentuate the importance of light, air and sunshine in securing and maintaining proper health conditions. The representations in the motion picture theaters will be specially designed to inculcate sound health principles. Special lectures for women on health questions of the hour will be provided. About fifty lectures and exhibits will be organized in industrial centers, dealing mainly with occupational hygiene and care of the health. The labor unions, the employers' associations, the medical profession, the motion picture corporations and the public welfare societies are working hand in hand to insure the success of the undertaking.

Marriages

Valcoulon Le Moyne Ellicott to Miss Mary Purnell Gould, both of Baltimore, April 5.

Louis William Perman, New York, to Miss Clara Lillian Wolff of Brooklyn, March 27.

Arthur H. Burleson to Miss Kittie Walkinshaw, both of Olivet, Mich., February 7.

Deaths

Horace John Howk ⊕ Mount McGregor, N. Y.; University of Michigan Medical School, Ann Arbor, 1907; member of the American College of Physicians; past president of the Saratoga County Medical Society; instructor of clinical pathology at his alma mater, 1907-1908; lecturer at the Albany (N. Y.) Medical College; on the staff of the Loomis (N. Y.) Sanatorium, 1908-1911; physician in charge, Metropolitan Life Insurance Company Sanatorium, and on the staff of the Glens Falls (N. Y.) Hospital; aged 47; died, April 8, at the Johns Hopkins Hospital, Baltimore.

Amos Gale Straw, Manchester, N. H.; Medical School of Harvard University, Boston, 1890; member of the Massachusetts Medical Society, the New Hampshire Medical Society and the Radiological Society of North America; served during the World War; local bacteriologist to the Manchester Board of Health; on the staffs of the Beacon Hill, Notre Dame and Balch hospitals; president of the staff of the Elliot Hospital and roentgen-ray expert to the U. S. Veterans' Hospital, no. 95, Northampton, Mass.; aged 61; died, March 13.

Max Kahn ⊕ New York; Cornell University Medical College, New York, 1910; associate professor of biological chemistry, Columbia University College of Physicians and Surgeons; chief of the department of metabolism, Israel Zion Hospital, Brooklyn; discoverer of "intarvin"; director of the laboratories and chief of the department of metabolism, Beth Israel Hospital, where he died, April 8, of heart disease, aged 39.

Harold Williams, New Bedford, Mass.; Medical School of Harvard University, Boston, 1878; member of the Massachusetts Medical Society; and the American Climatological and Clinical Association; emeritus professor of theory and practice of medicine, Tufts College Medical School, and formerly dean of Tufts College Medical and Dental schools; aged 72; died, April 3, at St. Augustine, Fla., of heart disease.

Jacob Gilbert Zern, Lehighton, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1868; member of the Medical Society of the State of Pennsylvania; Civil War veteran; past president of the Carbon County Medical Society; formerly postmaster of Weissport and member of the state legislature; aged 81; died, March 20, of senility.

Charles Edwin Donlan, Malden, Mass.; Medical School of Harvard University, Boston, 1898; formerly superintendent of the Boston Almshouse and Hospital, Long Island, and the Lowell (Mass.) Almshouse; at one time on the staff of St. John's Hospital, Lowell; Spanish-American War veteran; aged 52; died, March 30, at Miami, Fla.

Norman S. Campbell, Bark River, Mich.; Michigan College of Medicine and Surgery, 1902; member of the Michigan State Medical Society; president of the Delta County Medical Society; aged 46; died, February 23, at St. Francis Hospital, Escanaba, of septicemia, following burns received when his home was destroyed by fire.

Adams Bailey Howard ⊕ Cleveland; Medical Department of the University of Wooster, Cleveland, 1892; member of the American Psychiatric Society; formerly superintendent of the Cuyahoga Falls Sanitarium and the Cleveland State Hospital; aged 66; died, April 1, of pneumonia.

George Ross, Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1861; member of the Medical Society of Virginia; emeritus professor of obstetrics, Medical College of Virginia; Civil War veteran; aged 87; died in March, at Los Angeles.

Henry Reed Hopkins, Buffalo; University of Buffalo Department of Medicine, 1867; member of the Medical Society of the State of New York; emeritus professor of hygiene at his alma mater; aged 81; died, March 6, of embolism, myocarditis and arteriosclerosis.

Frederick B. Peabody ⊕ Richmond, Maine; Medical School of Maine, Portland, 1900; aged 50; died, March 23, at St. Barnabas Hospital, Portland, of myocarditis, following an operation for suppurative arthritis of the hip, a complication which followed the mumps.

Julius Rosenstirn, New York; University of Wurzburg, Germany, 1872; formerly on the staff of the Mount Zion Hospital, San Francisco; at one time connected with the George Crocker Special Research Fund of Columbia University; aged 76; died, March 27.

Walter Frank Cimiotti, Union City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1901; served during the World War; aged 48; died, March 28, at the Knickerbocker Hospital, New York, of chronic nephritis and cerebral hemorrhage.

Herbert Othello Darnall, El Paso, Texas; Hahnemann Medical College and Hospital, Chicago, 1902; member of the State Medical Association of Texas; served during the World War; aged 48; died, in March, at the William Beaumont General Hospital.

Frederick Converse Eastman, Lees Summit, Mo.; College of Physicians and Surgeons, Keokuk, 1865; Bellevue Hospital Medical College, New York, 1883; Civil War veteran; aged 83; died, March 21, at Kansas City, Mo., of influenza and myocarditis.

George Henry Cobb ⊕ South Orange, N. J.; Medical Department of Columbia College, New York, 1888; member of the Medical Society of the State of New York; president of the South Orange Board of Health; aged 63; died, April 5, of pneumonia.

John Winthrop Wright ⊕ Bridgeport, Conn.; Medical Department of the University of the City of New York, 1880; formerly on the staffs of the Bridgeport and St. Vincent's hospitals; aged 73; died, February 10, following an operation for gallstones.

Theodore J. Gramm, Philadelphia; Hahnemann Medical College of Philadelphia, 1881; on the staff of the Women's Homeopathic Hospital; one of the founders and on the staff of the Belmont Hospital; aged 65; died, April 9, of angina pectoris.

Judson Albertus Ferree ⊕ Columbus, Ohio; Cleveland-Pulte Medical College, Cleveland, 1901; University of Michigan Homeopathic Medical School, Ann Arbor, 1909; aged 52; died, March 29, at the Mount Carmel Hospital, of carcinoma.

Jesse Kersey Patrick ⊕ West Chester, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1915; aged 37; died in March, at the Chester County Hospital, from the effects of illuminating gas, presumably self-administered.

Mary D. Rushmore, Palmyra, N. J.; Woman's Medical College of the New Infirmary for Women and Children, 1894; for many years surgeon to the New York Infirmary for Women and Children; aged 59; died, February 3.

Fred Bain Weaver, Hyde Park, N. Y.; Albany Medical College, 1898; member of the Medical Society of the State of New York; aged 50; died, March 16, at the Vassar Hospital, Poughkeepsie, of pneumococcus meningitis.

William Redwood Fisher, Swiftwater, Pa.; Medical Department of Columbia College, New York, 1867; formerly on the staffs of the Bellevue Hospital, New York and St. Mary's Hospital, Hoboken, N. J.; aged 82; died, March 28.

Charles W. Packard, Stratford, Conn.; New York Medical College, 1855; member of the New York Pathological Society; Civil War veteran; on the staff of St. Luke's Hospital, New York; aged 93; died, March 27, of myocarditis.

George A. Gilbert, Danbury, Conn.; Medical Department of Columbia College, New York, 1883; formerly on the staff of the Danbury Hospital; for ten years member of the board of education; aged 67; died, March 27.

Carll Casper Method, Elmhurst, Ill.; Northwestern University Medical School, Chicago, 1925; aged 27; died in March, of injuries received when the automobile in which he was driving was struck by a train.

Fred Stroble Westmoreland, Spartanburg, S. C.; Medical College of the State of South Carolina, Charleston, 1904; member of the South Carolina Medical Association; aged 46; died, March 5, at Vienna, Austria.

Charles Edward McClelland ⊕ Columbus, Ohio; Ohio Medical University, Columbus, 1902; served during the World War; aged 47; died, March 27, at Rochester, Minn., following an operation on the spleen.

Llewellyn Powell Durrett, Louisville, Ky.; Louisville Medical College, 1892; member of the Kentucky State Medical Association; aged 58; died in March, at St. Anthony's Hospital, following an operation.

Roger Sherman Tracy, Ballard Vale, Mass.; Medical Department of Columbia University, New York, 1868; formerly member of the New York Department of Health; aged 84; died, March 6.

David Jones Hale, Terre Haute, Ind.; Rush Medical College, Chicago, 1905; member of the Indiana State Medical Society; aged 49; died, January 6, at the Union Hospital, of pernicious anemia.

John Schilling, Fort Wayne, Ind.; St. Louis College of Physicians and Surgeons, 1884; member of the Indiana State Medical Association; aged 62; died, March 20, of sclerosis of the spinal cord.

Carl Henry Breidenbach, Dayton, Ohio; Miami Medical College, Cincinnati, 1898; member of the Ohio State Medical Society; on the staff of the Miami Valley Hospital; aged 58; died, March 5.

George Allen Ross, Capac, Mich.; University of Michigan Medical School, Ann Arbor, 1909; member of the Michigan State Medical Society; aged 42; died in March, of pneumonia.

John M. Wilkins, Martinsville, Ill.; Vanderbilt University Medical Department, Nashville, 1878; Civil War veteran; aged 80; died, March 20, of valvular heart disease.

Alonzo Dexter Blagden, Sycamore, Ill.; Bennett Medical College, Chicago, 1886; member of the Illinois State Medical Society; aged 74; died, April 2, of heart disease.

John Van Reed Lyman ⊕ Eau Claire, Wis.; Rush Medical College, Chicago, 1880; aged 68; died, March 31, at the Wauwatosa (Wis.) Sanitarium, of pneumonia.

Joseph McNeece, Morley, Mich.; Detroit College of Medicine and Surgery, 1889; member of the Michigan State Medical Society; aged 62; died, March 22.

August Henry Madsen, Scenic, Wash.; Rush Medical College, Chicago, 1925; aged 29; died, March 16, at Leavenworth, of pneumonia, following influenza.

William C. A. Leipold, Chicago; Hering Medical College, Chicago, 1896; aged 63; died, April 2, of intestinal obstruction due to peritoneal adhesions.

Pattie Alonzo Moore, Oakton, Ky.; University of Tennessee College of Medicine, Memphis, 1901; aged 55; died, March 8, of carcinoma of the liver.

John Bryce McMurrich, Ste. Anne de Bellevue, Que., Canada; Trinity Medical College, Toronto, Ont., 1896; aged 53; died, Dec. 28, 1925.

Archibald Blyth Stewart, Rosthern, Sask., Canada; University of Manitoba Faculty of Medicine, Winnipeg, Man., 1889; aged 59; died recently.

Andrew Ten Brook, Bloomington, Ill.; Jefferson Medical College of Philadelphia, 1876; aged 72; died, March 30, of cerebral hemorrhage.

Staley N. Chapin, Chicago; Rush Medical College, Chicago, 1885; aged 77; died, March 28, of carcinoma of the tonsil and parotid gland.

Milton P. Tolliver, Elnora, Ind. (licensed, Indiana, 1897); formerly county coroner; aged 77; died, March 23, of cerebral hemorrhage.

Richard Holden Love, Saskatoon, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1899; aged 49; died recently.

John W. Miller, Wayne City, Ill. (licensed, Illinois, 1888); aged 78; died, March 11, at the Deaconess Hospital, St. Louis, of pneumonia.

Allen C. Gregg, Denver; University Medical College of Kansas City, Mo., 1896; aged 52; died, March 10, of pneumonia.

William F. Taylor, Fort Worth, Texas; Missouri Medical College, St. Louis, 1877; aged 77; died in March, of heart disease.

William Grant Bixler, Panama, Neb.; Lincoln Medical College, 1903; aged 61; died, February 14, following a long illness.

Elton Arthur Chloupek, Oak Park, Ill.; College of Physicians and Surgeons, Chicago, 1899; aged 51; died, April 3.

Silas W. Patton, Catlettsburg, Ky. (licensed, Kentucky, 1894); aged 79; died, February 28, of senility.

Ferdinand Fischer, Carlyle, Ill.; Eclectic Medical Institute, Cincinnati, 1879; aged 76; died, March 28.

Correspondence

GLUCOSE AS A FOOD

To the Editor:—I read with much interest the editorial on "Glucose as a Food" (The Journal, Feb. 27, 1926). I was greatly surprised to find that this editorial was cited as one of the reasons before the Interstate and Foreign Commerce Committee of the House of Representatives favoring the approval of the bill already passed by the Senate, permitting the use of glucose as a component of sugar under the general title of sugar, and without notice to the consumer. I notice that your approval of this measure is not because of its repealing some of the most important provisions of the food law, and the legalization of adulteration and misbranding, as it is because of the value of glucose, which you describe as *par excellence* the physiologic sugar.

It is true that the only sugar found in the blood and tissues is glucose. You may be surprised, however, to find that this pending legislation is urged because it is hoped to supply two billion pounds of this sugar to the American consumer by reason of the permission to adulterate ordinary sugar without notice to the consumer. In order to make this amount of sugar, in round numbers, two billion pounds of starch must be extracted from its natural surroundings, converted into glucose *vi et armis*, and given in this form to the American consumer. Starch never exists free in nature. All the starches are parts of food products containing practically all the essential elements of nutrition. Starch by itself builds practically only one tissue; namely, fat. It is entirely deficient in vitamins and minerals, and as a food product, fed in any considerable quantity, would tend to develop diabetes, beriberi, xerophthalmia, scurvy, and many other diet deficiency maladies. It would present to the human stomach two billion additional pounds of prechewed and predigested starch, thus taking away from the natural digestive processes a large part of their functions, and in accordance with the well known principles of physiology, injuring to this extent the ability to digest starches and thus threaten the health and welfare of the whole body of American consumers.

When starch is converted into glucose by the natural processes of digestion, which at the same time are exerted on other necessary food products containing both vitamins and minerals, we have a natural production of glucose in which all the functions of mastication and digestion have received their full exercise.

By the pending measure all of these natural functions are obliterated, with the dangers to health and vitality already enumerated. It is extremely painful to see so excellent and scientific a journal as that of the American Medical Association quoted in support of such an unethical pending legislation.

Harvey W. Wiley, M.D., Washington, D. C.

[Comment.—The point of view of the foremost champion of the "pure food laws" in this country has been presented in full, so that his contentions may be available in his own words to our readers. It might be well also to reread carefully the editorial in question (The Journal, February 27, p. 628). Dr. Wiley does not take exception to the well established chemical and physiologic facts there reviewed. He argues that glucose (corn sugar) is prepared from isolated starch, a product that "never exists free in nature"; so that the resulting artificially produced sugar will be devoid of the vitamins and the minerals that the naturally occurring starch-bearing foods carry along with the carbohydrate. Consequently, one readily infers, the liberal use of pure glucose might lead to an undesirable deprivation of certain food accessories essential to our nutritive well being.

The same argument may be applied, however, with equal cogency against the widespread use of the common table sugar, sucrose—a product supplied everywhere in almost chemically pure form rather than as it occurs in nature. The sugar consumption of the United States now exceeds 100 pounds per capita per annum. Why the use of pure glucose should be singled out as more harmful, from the particular standpoint taken, than is the liberal consumption of the equally pure and isolated sucrose, is not made clear. Dr. Wiley avers that starch is a fat-former; but so are all the common sugars of commerce, to which no specific objection is made on that score. Furthermore, if our correspondent's contentions were carried to their logical conclusion, all purified foodstuffs would come under the same ban, whether they are corn starch, sugars, gelatin, or refined fats such as now enter widely into the American dietary.

Whether the replacement of starchy foods, slower of digestion, by sugars and the consequent "sparing" of the digestive organs with a simultaneous "flooding" of the alimentary tract with predigested foodstuffs is a physiologic detriment may well be argued as our correspondent has ventured. Whether the current use of overrefined and overmilled foods tends to bring about dietary deficiencies which the corresponding consumption of "natural" foods would be less likely to entail is likewise a problem of paramount importance. These questions should, we believe, be argued on their inherent merits and not be confused with the less tenable thesis that, in contrast with the consumption of pure sucrose from sugar cane or sugar beets, the dietary use of glucose is unwarranted. More than this our editorial has not discussed; nor should The Journal be expected to accept responsibility for any unwarranted deductions that may have been made from it.—Ed.]

MASS CANCER INCIDENCE NEAR BAKERIES AND IN OTHER PLACES WHERE RATS ABOUND

To the Editor:—In the Paris letter (The Journal, Sept. 12, 1925, p. 838) there was a report of investigations by Negre in the French Tarn district on mass cancer incidence near bakeries and other places where rats abound. The matter constitutes apparently further corroborative evidence for parallel observations found in the literature. It seems that various worms can be among the cancer-inciting factors, and that rats can be the carriers of these worms and their larvae and the disseminators of their ova. As others may also be interested in the matter, I cite some references: In "Some Notes on Cancer" (*J. Cancer Research* **8**:45 [April] 1924) I mentioned certain cancer districts. L. W. Sambon (The Elucidation of Cancer, *J. Cancer* **2**:37 [Jan.] 1925) showed the coincidence of a high cancer rate, old bakeries, cockroaches and rats. In a second article entitled "Some Notes on Cancer" (*Am. J. M. Sc.* **170**:481 [Oct.] 1925) I described worms, their ova and larvae as cancer-inciting factors.

Willy Meyer, M.D., New York.

HEMORRHAGIC NEPHRITIS

To the Editor:—In The Journal, April 3, in an article by George Baehr entitled "A Benign and Curable Form of Hemorrhagic Nephritis," the author says: "In the English and American literature nothing more than extremely casual references have come to my notice."

Dr. Baehr appears to have missed seeing a paper by Drs. J. P. O'Hare and W. G. Walker in the *Atlantic Medical Journal* (**27**:280 [Feb.] 1924) under the title, "Hemorrhagic Nephritis," in which attention is called to this form of renal lesion. Also in the Oxford Medicine, Chapter XI, by myself and Dr. O'Hare this is discussed on pages 721 to 739. Here attention is called to the frequency of the hemorrhagic type of nephritis, forty-seven cases having been seen by us at the Peter Bent Brigham Hospital in ten years, and it having constituted 25 per cent of the nephritic cases observed among children by L. W. Hill (The Journal, Dec. 6, 1919, p. 1747; *Am. J. Dis. Child.* **17**:270 [April] 1919).

In Oxford Medicine there is not a subgrouping of these cases into benign and progressive forms, though the recoverability is indicated under "Prognosis," where appears the statement, "Numerous cases get well though the progress to recovery may be slow. Most are long drawn out and many gradually progress downward as a chronic nephritis without edema."

I agree with all of Dr. Baehr's statements and feel that the hemorrhagic group is a very important type of nephritis. My own experience, however, has not yielded the striking improvement following tonsillectomy. Following tonsillectomy usually I have observed a prolonged continuation of the hematuria, sometimes with eventual disappearance, at other times with progression into a chronic form of nephritis eventually fatal.

Henry A. Christian, M.D., Boston.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF ECZEMA

To the Editor:—I would be pleased to know something of the latest advances made in the treatment of eczema. Is there any known treatment that is really worth while, or that shows results—any kind of treatment, medication, light therapy, serum treatment, or any other kind in your knowledge? Can you suggest anything or refer me to any articles of promise?

Verner I. Baugh, M.D., Girard, Texas.

Answer.—The greatest recent advance in the solution of the eczema problem has been the recognition and separation from eczema of eczematoid ringworm. Many cases formerly classed as eczema are now recognized and treated successfully as ringworm (White, C. J., and Greenwood, A. M.: Epidermophytosis, *Wisconsin M. J.* **24**:1 [June] 1925; *Illinois M. J.* **48**:269 [Oct.] 1925).

A second, constantly increasing group separated from eczema, though very closely related to it, is that of dermatitis from external irritants. Careful detective work will sometimes discover the cause of a dermatitis in some substance with which the patient comes into frequent contact. Hair dyes, dyed furs, house plants, lacquered wooden articles, and colored newspaper supplements are a few of these. Sensitization to external and internal irritants must be considered in these cases. Skin tests with proteins give help in some cases, though often disappointing and sometimes actually misleading (O'Keefe, E. S.: Protein Sensitivity in Children with Negative Cutaneous Reactions).

Focal infection must be considered as a possible cause (Vischer, J. W.: The Rôle of Focal Infection in the Etiology of Eczema, *Am. J. M. Sc.* **170**:723 [Nov.] 1925).

Faulty metabolism and inefficient excretion may be to blame (Schamberg, J. F., and Brown, H.: Relationship of Excess of Uric Acid in the Blood to Eczema and Allied Dermatoses, *Arch. Int. Med.* **32**:203 [Aug.] 1923; Study of Blood Uric Acid in Diseases of Skin, *Arch. Dermat. & Syph.* **8**:801 [Dec.] 1923. McGlasson, I. L.: Hyperglycemia as an Etiologic Factor in Certain Dermatoses, *ibid.* **8**:665 [Nov.] 1923. Ayres, Samuel, Jr.: Glucose Tolerance Reactions in Eczema, *ibid.* **11**:623 [May] 1925).

Endocrine disturbances must always be considered. The roentgen ray, usually in a dosage of one-fourth skin unit once a week, gives at least temporary relief in most cases. Ultraviolet rays give relief in some cases, though they must be used with caution in acute exacerbations and in hyperglycemia.

Mild foreign protein injections may be helpful, acting possibly by desensitizing the patient. Autoserum injections, either intramuscular or intravenous, are probably of this nature. Milk injections intramuscularly, or bacterial vaccines used in the same way, may help. Severe reactions should be avoided.

The use of crude coal tar ointment has been of great value in the treatment of adult as well as infantile eczema (White,

C. J.: Infantile Eczema and Examination of the Stools, *Arch. Dermat. & Syph.* **7**:50 [Jan.] 1923).

The nervous system assumes an important rôle in the causation of many cases. Sedatives, usually bromides, are often valuable.

IMMUNIZING AGAINST EGG

To the Editor:—I will appreciate any advice you can give me concerning the method and technic of immunizing a patient against egg. My patient is so hypersensitive to both egg white and yolk that a minute quantity, and often just the odor of cooking eggs, will give her asthma.

Last April I procured a freshly prepared quantity of whole egg antigen in solutions of from 1: 500 to 1: 10,000. I first tested her out for beginning dosage, getting a reaction (local) to everything above 1: 120,000, and began with 0.15 cc. of that dilution. Injections were given twice a week, increasing from 0.15 to 0.20 cc. each injection with no general reaction and only slight local reaction, until 0.60 cc. of a 1: 80,000 dilution was reached, when the arm showed a marked local reaction, being swollen and red. However, by repeating this dose twice I was able to get past it and continued to progress without difficulty until almost through the 1: 5,000 dilution, when the local reactions became severe. In spite of some local reaction with each injection, I worked up to the 1: 1,000 strength, when the patient had a sharp attack of asthma requiring epinephrine. I then reduced the dose but kept the same dilution, each time, however, getting a varying amount of local and general reaction. After this I suspended treatment two weeks, resuming with 1: 10,000 dilution, but with each injection there was a marked local reaction. Concluding now that I was getting nowhere, I gave up the attempt.

My experience suggested to me that I was raising the immunity for a time and then she lost it and became as sensitive as ever. Wherein was the technic at fault?

Wilbur T. Little, M.D., Canon City, Colo.

Answer.—If it is feasible, eggs should be excluded completely from the patient's diet. If this is too great a hardship in the management of the household, the following mode of desensitization might be tried, but during the period of desensitization no eggs whatever should be eaten, not even food that contains even a trace of egg white or egg yolk:

One drop of egg white, taken with a medicine dropper, is mixed with 1 quart of water and well shaken. Of this first dilution, 20 drops is shaken well with another quart of water.

Of this second dilution, one teaspoonful is taken daily by mouth for one week. In the second week the dose should be increased every day one teaspoonful, so that the patient takes on the eighth day two teaspoonfuls, on the ninth three, on the tenth, four, and so on. In the third week half a tumbler of the second dilution should be taken daily by mouth; in the fourth, a whole tumbler daily.

In the fifth week, 20 drops of the first dilution (1 drop of egg white and 1 quart of water) should be placed in a glass of water and taken daily by mouth, and this increased by 20 drops every week and taken daily until the patient reaches one teaspoonful or 1 fluidrachm; after that she should continue to increase every week 1 fluidrachm, taking a dose daily, to 2, 3, 4, 5, 6, 7 fluidrachm, etc. In the twelfth week, 3 ounces; in the fourteenth, 6 ounces.

If the patient is so sensitive that she cannot tolerate even the dilutions suggested, the same dilutions should be made and the desensitization attempted with them by the rectal route.

GRAM STAIN

To the Editor:—Is there some method for gram staining in which a stable stock solution of gentian violet may be used?

M. B. Rosenblüth, M.D., New York.

Answer.—The usual methods of preparing the aniline-gentian violet stain for use in the Gram method of staining bacteria require freshly prepared mixtures, owing to the instability of the stain so made. Sterling has introduced, however, a formula for such a stain that has proved very reliable and satisfactory and has the advantage that it will remain permanent for three or four months. The formula is: gentian violet, 5 Gm.; alcohol, 95 per cent, 10 cc.; aniline, 2 cc.; distilled water, 88 cc. The aniline and the alcohol are thoroughly mixed by shaking, and the water is added. Now the gentian violet is ground in a mortar, and the aniline solution added slowly until the stain is practically dissolved. The solution is filtered into a staining bottle.

Instead of using this stain, one may substitute with satisfactory results a 0.5 per cent aqueous solution of methyl violet 6 B, which is very permanent and has been advocated by many workers for use in the Gram method of staining. When the latter solution is used, it is advisable to use a somewhat stronger iodine solution in the second step of the staining process than is used with the gentian violet solution. The formula for this iodine solution is: iodine, 1 Gm.; potassium iodide, 2 Gm.; distilled water, 100 cc.

SENSITIZED BACTERIAL VACCINES

To the Editor:—May I ask your opinion regarding the relative value of "sensitized bacterial vaccines" as compared with the ordinary type? I am especially interested in the so-called triple vaccine against typhoid infections. In a series of three vaccinations with these bacterins reaching back through the last ten years, I have experienced an increasingly severe reaction from vaccine. On the last occasion, I was almost disabled for more than three weeks, and I have seen somewhat similar reactions in some of my patients. It has been suggested to me that the "Sero-bacterins" made by a well known house would markedly diminish the disturbing reaction. I have usually employed United States government vaccine in work with members of the R. O. T. C. and on my own person, and otherwise, more commonly Parke, Davis & Company's. A bacteriologic friend of mine has suggested that the difficulty might be lessened by the elimination of the paratyphoid vaccine, but one does not like to forego the protection against this infection. I should be very grateful for your opinion on this matter and for reference to any literature which you might suggest.

Arthur V. Stoughton, M.D., Claremont, Calif.

Answer.—There is no evidence that "sensitized bacterial vaccines" have greater protective power than simple vaccines. Sensitized vaccines, though claimed to have certain advantages (New and Nonofficial Remedies, 1925, p. 367), are objectionable because they may sensitize the injected person to the proteins in the animal serum with which the bacteria of the vaccine have been treated. With the sensitized vaccine there is injected into the body additional and undesirable foreign protein. Three series of vaccinations with triple typhoid vaccine in ten years is going further than seems to be necessary. Obviously, the recipient is in an allergic or sensitive state and further injections of any kind of typhoid vaccine are not at all indicated. Well vaccinated persons appear to be protected for an indefinite time; in the U. S. Army, two courses of injections are given at an interval of three years. This at present may be regarded as our best standard. Unfortunately, there is not available a simple test, like the Schick test in the case of diphtheria or the Dick test for scarlet fever, that will tell whether a person is susceptible or not to typhoid infection. The problems of antityphoid vaccination have been discussed recently in an able and rational manner by H. J. Nichols and Parker Hitchens (The Reactions of Typhoid Vaccination, *J. Lab. & Clin. Med.* **11**:517, 1926).

PREVENTION OF RENAL CALCULUS

To the Editor:—I would appreciate it greatly if you will outline for me the proper diet and other preventive measures to be taken in order to avoid the recurrence of renal calculus (calcium oxalate). Recently a calcium oxalate stone was removed from my ureter. Please do not publish my name.

M.D., New York.

Answer.—One of the most important things in the prevention of recurrence of stone is dilution. The patient should be instructed to drink a large amount of water so as to keep the specific gravity of the urine below 1.005. Two factors that are supposed to play an important part in the recurrence of oxalate stone are an excessive nitrogenous intake coupled with an excretory sluggishness.

It would be advisable to carry on with a low nitrogenous diet. Alcohol, tea, coffee and tobacco should be used sparingly and the bowels kept open. The patient should of course take a certain amount of exercise—outdoors, preferably—that will make him perspire. Repeated roentgen-ray examination should be made from time to time so that if stone does recur it will be recognized early, at which time it can be treated by dilating the ureter with bougies and injecting oil to aid the stone in its passage down the ureter.

Should there be stasis in the upper urinary tract, such as hydro-ureter or hydronephrosis due to stricture of the ureter, this should be treated with dilation.

PREGNANCY FOLLOWING THYROIDECTOMY

To the Editor:—1. What effect will pregnancy have on a patient who has suffered from a toxic goiter, which was operated on about four years ago and the patient having been in fair health since? With the first pregnancy there was some disturbance with the thyroid, and a severe toxic thyroid developed following the second pregnancy, with exophthalmos, fast pulse, enlarged gland, and frequent bowel movements. 2. Is it generally taught that primiparas usually go into labor two or three weeks before the calculated time? Kindly omit my name.

M.D., South Dakota.

Answer.—1. If the patient's heart has been affected, she should be treated like other women who have heart trouble. If the heart is in good condition, pregnancy will most likely have no ill effects on the patient, though the baby may be influenced unfavorably. When a pregnant woman has a diminished output of thyroid secretion because of congenital deficiency, operation or other cause, the baby frequently is born with an enlarged thyroid. This is most likely a compensatory hypertrophy to make up for the maternal deficiency. In some instances the thyroid enlargement in the new-born persists for a long time and is troublesome. To avoid this condition in the new-born, the mother during pregnancy should receive compound solution of iodine, 5 drops, twice a day for one week. After an interval of a few weeks, the solution should again be taken for one week.

2. While primiparas often go into labor a few weeks before term, it is not the rule for this to occur. Old primiparas have a tendency to go beyond term.

TREATMENT OF PINWORMS

To the Editor:—Please advise if there is any effective way of ridding a child or an adult of pinworms. The following has already been used and found inadequate: santonin and calomel, one-half grain of each daily for four days; twenty-four hours' fast; administration of oil of chenopodium, 8 drops, with 1 ounce of castor oil together; nightly enemas of infusion of quassia, and anointing of anus with ointment of ammoniated mercury. The cooperation of the patient has been excellent, but the worms are still present.

M. W. HOLLINGSWORTH, M.D., Santa Ana, Calif.

ANSWER.—In obstinate cases, the attack should be carried on simultaneously from above and below. One santonin tablet (0.03 Gm.) three times daily for three days should be combined with daily rectal irrigations of vermicidal solutions. It is stated that 1 per cent soap solution kills the pregnant females. Vinegar (from 30 to 100 per thousand) is also recommended. After two weeks the process is repeated. During this entire time most painstaking prophylaxis must be kept up, especially scrupulous cleanliness of the anal region and the wearing of closed drawers day and night. Over night the following ointment may with advantage be applied to the anus:

		Gm.
℞	Ethyl aminobenzoate (benzocaine)	2
	Salicylic acid	0.5
	Hydrous wool fat	20

The hands must be kept carefully clean, being washed thoroughly and long with soap and water after dressing and after each bowel treatment. It must be admitted that, in spite of most careful treatment, complete eradication is at times impossible; but the infestation may be kept sufficiently low to maintain the patient symptom-free.

TOXIN-ANTITOXIN AND ASTHMA

To the Editor:—Please advise me as to the risk, if any, in giving toxin-antitoxin to a child who has known asthmatic attacks.

J. G. LOGUE, M.D., Williamsport, Pa.

ANSWER.—If the asthmatic attacks are precipitated by coming in contact with horses or emanations from horses, it would seem possible that alarming symptoms might develop after toxin-antitoxin injection because of the presence of horse proteins in the antitoxic serum used in making the toxin-antitoxin mixture. Recently Bauer and Wilmer (Toxin-Antitoxin, Hypersensitivity to Its Protein Content, THE JOURNAL, March 27, p. 942) report, however, that in their experience, which seems to be large, children sensitive to horse protein did not react to the toxin-antitoxin mixture. But in any case, injection of foreign protein in asthmatic persons ought to be done with especial care and only when indicated clearly.

DETERMINATION OF MENTAL DEVELOPMENT

To the Editor:—I have a backward baby under treatment who is showing a tendency toward mongolism, and whose parents wish to check up his mental development at intervals. Do you know of any set of test questions that would be of service under the circumstances, and, if so, where I could procure copies?

ERLE DRAPER, M.D., Bedford, Quebec.

ANSWER.—The tests in most common use are those of the Stanford revision of the Binet scale. The materials for these tests can be obtained from the Houghton, Mifflin Company, which has offices in Boston, New York and Chicago.

DECREASING APPETITE

To the Editor:—Is there any drug, or combination of drugs, which taken by mouth will decrease the appetite without deleterious effect on the health? Please omit my name.

M.D., Ohio.

ANSWER.—Probably not.

Utah February Reciprocity Report

Mr. J. T. Hammond, director of the Department of Registration of Utah, reports that 8 candidates were licensed by reciprocity at a meeting held Feb. 5, 1926. The following colleges were represented:

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Drake University College of Medicine	(1910)	Iowa
University of Maryland School of Medicine	(1924)	Penna.
University of Nebraska College of Medicine	(1925, 3)	Nebraska
Ohio State University College of Homeo. Medicine	(1921)	Ohio
Jefferson Medical College of Philadelphia	(1908)	Penna.
Wisconsin College of Physicians and Surgeons	(1905)	Wisconsin

Washington January Examination

Mr. William Melville, director of the Department of Licenses of Washington, reports the oral and written examination held at Olympia, Jan. 11-13, 1926. The examination covered 13 subjects and included 130 questions. An average of 75 per cent was required to pass. Of the 6 candidates examined, 5 passed and 1 failed. Thirty-two candidates were licensed by reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
University of Virginia Department of Medicine	(1924)	80
University of Alberta Faculty of Medicine	(1925)	83.5
University of Manitoba Faculty of Medicine	(1914)	77
McGill University Faculty of Medicine	(1913)	76
University of Kief, Russia	(1893)*	75

College FAILED	Year Grad.	Per Cent
Washington University School of Medicine	(1908)	†

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

* Verification of graduation in process.

† No grade given.

‡ This candidate has completed his medical course and will receive his M.D. degree on completion of a year's internship in a hospital.

Book Notices

Life and Evolution. An Introduction to General Biology. By S. J. Holmes, Ph.D., Professor of Zoology in the University of California. Cloth. Price, $3.50. Pp. 449, with 227 illustrations. New York: Harcourt, Brace & Co., 1926.

The principal title of this new book by a prolific writer is considerably less indicative of its contents than is the subtitle. If one bought the book with the idea of getting a new statement about the much debated theory of evolution one would be disappointed, for only the last third of the book deals with evolution, and the treatment is unusually orthodox. The main part of the book is devoted to an exposition of the principles of biology, mainly those usually brought out in textbooks of general zoology. Dr. Holmes has followed traditional lines so far as content is concerned, but has ventured to modify the manner of presentation in some respects. In order to make the book more readable for the casual reader, he has discarded most of the tried and proved pedagogic devices employed by textbook writers. Thus, the chapters read straight ahead without topical subtitles or paragraph heads. The use of differentiated type for emphasis or to aid in making clear the organization is also dispensed with. What the book gains for the general reader, if anything is really gained, is lost for the student. The book differs little in content from standard textbooks on general zoology. To be sure, there is a chapter of sixteen pages on the green plant, but the rest of the treatment is strongly zoological. It will therefore hardly satisfy those instructors who prefer a course about equally divided between botany and zoology. The literary style is facile and interesting enough to make it good reading for one who is intent on getting an orthodox statement about the prevalent ideas and facts of modern biology.

Microbe Hunters. By Paul de Kruif. Cloth. Price, $3.50. Pp. 363, with illustrations. New York: Harcourt, Brace & Co., 1926.

It is a fascinating story: the discovery of microbes, how they grow, what diseases they cause in man and animals, and finally the means of protecting mankind against them. De Kruif has told, in highly dramatic form, the lives of the principal characters in the story, from Leeuwenhoek, who first saw microbes through the lenses of his own making, to Paul Ehrlich, discoverer of the "magic bullet" which could destroy the spirochete of syphilis. The curiosity that drove these men to endless searching for the causes of disease in spite of all discouragement, their adventures, failures and successes, are all vividly portrayed. In many places the tale of their adventures reads like a romance. Indeed, few romances can offer more exciting material than the search of Bruce for the cause of trypanosomiasis and the final tracking down of the tsetse fly, or Walter Reed's discovery of the transmission of yellow fever by mosquitoes. The discoverers, as they appear in these pages, are far from the perfect and rather priggish members of the human race that they are sometimes represented to be. De Kruif writes as though he knew each one intimately, were in his confidence, and had special insight into his actions. The variety of character is most interesting. Pasteur's truly brilliant inspirations, "shooting out like a display of village fireworks going off bewilderingly by accident," sometimes indeed overshooting the mark and given to the world prematurely, stand in sharp contrast to Koch's colder and more precise methods. Then we are told of Metchnikoff's extraordinary career, his sudden jumps to unheard-of conclusions, his alternating attempts to commit suicide and to find the means of prolonging life indefinitely. The jealousies and disputes that arose among them, their undignified wranglings, as when the French surgeon Guérin rose from his seat and "aimed a wallop" at Pasteur, show them to have suffered from the common defects of ordinary mankind. Pasteur and Koch, in their excessive patriotism, denounced each other's discoveries, and later Ross and Grassi engaged in a violent quarrel over the priority in discovering the mosquito that transmits malaria. Unfortunately, doubtless in the effort to present the material in a vivid and dramatic manner, the style has taken on an exaggerated quality which is annoying. "Devilish," "infernal" and "hellish" are the adjectives frequently used, and one gets the impression that most of the hunters were insane, or at least half mad at some time in their careers. We hear of Walter Reed that "never was there a good man who thought of more hellish and dastardly tests." The slangy expressions also seem out of place, such as a demonstration by Koch that was a "knockout" before various "bigwigs," and, concerning some work of Roux, "scientific searchers . . . have held their noses at such an experiment." These give the book somewhat the quality of the best seller in fiction. However, the material throughout is extremely interesting, and will prove so to scientists and to others alike. The lives of the discoverers are an inspiration to other workers, and it is pleasant to find them so very human, and "yet not untouched with a halo of divine romance."

Lehrbuch der Lokalanästhesie des Ohres und der oberen Luft- und Speisewege. Von Dr. Caesar Hirsch, Chefarzt der Abteilung für Hals-, Nasen und Ohrenkranke des Marienhospitals in Stuttgart. Mit einem Vorwort von Professor Dr. O. Voss, Direktor der Universitätsohrenklinik in Frankfurt a. M. Paper. Pp. 293, with 104 illustrations. Stuttgart: Ferdinand Enke, 1925.

Beginning with a discussion along general lines on the subject of pain, local anesthesia, and the description of various drugs used in producing the anesthesia, the author takes up the various methods and the production of local anesthesia. He at first describes the so-called superficial anesthesia by means of local application to the skin or mucous membrane. Then the matter of the use of anesthesia by injection is described, together with the instruments. The second section of the book refers to operations on the scalp, ear, face and nose, and describes them in detail. This is followed by a chapter concerning operations on the mouth, pharynx and neck. This work details precisely the methods of producing local anesthesia in the parts under discussion, and there are excellent illustrations. A bibliography is appended to this readable and instructive work.

A Textbook of Pathology, General and Special. For the Use of Students and Practitioners. By J. Martin Beattie, M.A., M.D., L.R.C.P., Professor of Bacteriology, University of Liverpool, and W. E. Carnegie Dickson, M.D., B.Sc., F.R.C.P., Pathologist to the West End Hospital for Nervous Diseases, London. Third edition. Cloth. Price, $11. Pp. 1103, with 516 illustrations. St. Louis: C. V. Mosby Company, 1925.

Originally, the two parts of this work, "General Pathology" and "Special Pathology," were published as separate volumes. The present edition may be procured in two volumes, as before, or combined in one. The authors state in the preface that the second edition was long overdue, largely because of their participation in the World War; and that in this edition minor alterations and additions have been made to bring the material up to date. The two volumes of the first edition were separately reviewed in The Journal in 1909 and 1910. At that time, the review of the section on general pathology was not entirely favorable. The criticism was made that some important subjects were omitted altogether and that other subjects were treated in so brief a manner as not to satisfy an ardent student. The review of the section on special pathology was distinctly unfavorable, and on the same grounds. Apparently the reviewers, entirely within their rights, kept the previous editions, as they are not at hand for comparison. In the present edition, some of the omissions specifically mentioned in the previous reviews are supplied; not all of them. The authors seem to have had very clearly in mind the sort of work they intended originally to produce and have persisted in their original intention. Certain subjects for which the student would have small use are treated superficially. Foundational processes, such as inflammation and repair, are treated at length. In the fifteen years since the first edition was published, medical education, at least in America, has changed greatly. The present-day American student, struggling to keep his poise in the welter of our curriculums, will find in this Edinburgh book a coherent presentation of the second most difficult subject with which he has to make acquaintance. He can link up this material with the clinical medicine and surgery of his succeeding years in school and in practice. The authors apparently have decided that controversial and discursive material can wait until the student has the background to assimilate it. Admirable illustrations throughout the text help to establish such a background.

Abhandlungen aus der Neurologie, Psychiatrie, Psychologie und ihren Grenzgebieten. Herausgegeben von K. Bonhoeffer. Heft 34. Der heutige Stand der Behandlung der progressiven Paralyse. Von Dr. Ladislaus Benedek, o. ö. Universitätsprofessor, Vorstand der neurologischen und psychiatrischen Klinik der Stefan Tisza-Universität in Debreczen (Ungarn). Paper. Price, 15 marks. Pp. 219, with 25 illustrations. Berlin: S. Karger, 1926.

The author first gives as background a general discussion of the clinical and histologic evidences for the possible curability of general paralysis. He takes up the Staussler Jakob theory that general paralysis histologically is usually a general nonspecific reaction to the spirochete or its toxic products, but that in certain cases evidences of a specific and beneficial tissue reaction in the form of miliary gummas are present. The author fails to consider Spielmeyer's probably correct interpretation of the supposed gummas as local accentuations of the general inflammatory process. The etiology is considered from all aspects. There is a short discussion of the relation of the spirochetes to the brain changes. All the existent theories as to the pathogenesis of general paralysis are given. Sixty-three full case reports show the effects of the immune serum treatment, which is the use of the serum of horses immunized over a period of two months with extracts of paretic brains. Only 9.5 per cent of patients thus treated showed improvement. The treatment by fever production through injection of tuberculin, vaccines, nucleic acid and milk is discussed, but favorable results are not reported. The malaria treatment is taken up at length and the detailed technic given. The author's series of cases showed improvement in 35 per cent, which is slightly better than that reported from other clinics. Arsenical therapy, including the Swift-Ellis and the Gennerich method, are described. Tryparsamide is omitted probably because it is not obtainable in Hungary.

The Pathology of Tumours. By E. H. Kettle, M.D., B.S., Professor of Pathology and Bacteriology, Welsh National School of Medicine, Cardiff. Second edition. Cloth. Price, $5. Pp. 285, with 159 illustrations. New York: Paul B. Hoeber, Inc., 1925.

Amplified portions dealing with etiology, experimental research, carcinoma and endothelioma and thirty-three new illustrations are in this edition. The ending "ata" has been retained for names of tumors, notwithstanding the increasingly prevalent use of English plurals. In the plain, but adequate, illustrations, great care has been displayed. The "special pathology" or distribution of tumors in special regions, occupying the final fourth of the work is very abbreviated in spots, merely a list or syllabus of what may happen. The work has already met approval as a manual.

Lead Poisoning. By Joseph C. Aub, Lawrence T. Fairhall, A. S. Minot, and Paul Reznikoff. With a chapter on the prevalence of industrial lead poisoning in the United States by Alice Hamilton, from the Department of Physiology, Harvard School of Public Health, and the Medical Clinic, Massachusetts General Hospital. Cloth. Price, $4. Pp. 265, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

This is the seventh of the "Medicine Monographs" published by this firm, and that it is written and published here is gratifying because it is the type of monograph we have been accustomed to finding in German or French. Except for its legal bearings, all phases of lead poisoning are thoroughly considered. A great deal that is new from work by the authors is included, and of such portions those dealing with the physical and physiologic chemistry of plumbism are preeminent. That only 500 of the 2,200 references in their files were used gives some index of the care employed and the scope of the work.

Abdominal and Pelvic Surgery for Practitioners. By Rutherford Morison, Hon. M.A. and D.C.L., Hon. LL.D., M.B., Consulting Surgeon, Royal Victoria Infirmary and Dental Hospital, Newcastle-on-Tyne. Cloth. Price, $2.75. Pp. 212, with 9 illustrations. New York: Oxford University Press, 1925.

This is not intended as a complete treatise, but the clarity of thought and simplicity of style of the author make it profitable and enjoyable reading. Abdominal emergencies, subacute abdominal diseases and chronic abdominal and pelvic diseases are the subjects covered. The work ends with a brief chapter on postoperative complications and treatment. The bulk of material covered represents diagnosis; little attention is devoted to treatment except in the numerous case reports cited. The book is worthy of a place in the library of every practitioner.

Handbuch der experimentellen Therapie Serum- und Chemotherapie. Ein Handbuch für die arztliche Praxis und Klinik. Herausgegeben von A. Wolff-Eisner. Second edition. Paper. Price, 35 marks Pp. 790, with 69 illustrations. Munich: J. F. Lehmanns, 1926.

So far as important recent American work is concerned, this book presents "Nichts neues." The scarlet fever work is not discussed at all. The book cannot be recommended as giving an adequate idea of the present state of knowledge in its field.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Die Chirurgie. Eine zusammenfassende Darstellung der allgemeinen und der speziellen Chirurgie. Herausgegeben von Prof. Dr. M. Kirschner, Direktor der chirurgischen Klinik der Universität Königsberg i Pr., und Prof. Dr. O. Nordmann, Dirigierender Arzt am Auguste-Viktoria-Krankenhaus, Berlin. Lieferung 7. Nahtchirurgie. Von Priv.-Doz. Dr. E. Gohrbandt. Die allgemeine Lehre von den eitrigen Infektionen (einschliesslich septische Allgemeininfektion). Von Priv.-Doz. Dr. A. Buzello. Die allgemeine Lehre von den spezifischen Infektionen. Von Prof. Dr. R. Eden und Priv.-Doz. Dr. P. Drevermann. Paper. Price, 17 marks. Pp. 936, with illustrations. Berlin: Urban & Schwarzenberg, 1926.

More parts of German system of surgery, dealing this time with surgery of specific infections.

Die Biologie der Person. Ein Handbuch der allgemeinen und speziellen Konstitutionslehre. Herausgegeben von Prof. Dr. Th. Brugsch und Prof. Dr. F. H. Lewy. Lieferung I. Einführung in die Konstitutionslehre, ihre Entwicklung zur Personallehre. Von Prof. Dr. Th. Burgsh. Das Problem der Individualität. Von Dr. E. Straus. Die rechnerische Auswertung statistischer Beobachtungsergebnisse (Einführung in die Kollektivmasslehre). Von Dr. H. Salinger. Bedeutung des Normbegriffes in der Personallehre. Von Prof. Dr. I. Kaup. Allgemeine Vererbungslehre. Von Prof. Dr. W. Johannsen. Paper. Price, 15 marks. Pp. 322, with 22 illustrations. Berlin: Urban & Schwarzenberg, 1926.

First part of new system of human biology.

Die Bluttransfusion. Von Privatdozent Dr. B. Breitner, I. Assistent der I. chirurgischen Universitäts-Klinik in Wien. Paper. Price, 6.90 marks. Pp. 113, with 24 illustrations. Vienna: Julius Springer, 1926.

Monograph with bibliography. Literary study is incomplete, and conclusions are not in accord with best modern American practice.

Pleomorphism in Bacterial Protoplasm. A Study in Psittacosis. By Andrew Todd McClintock, M.D. Archives of the Andrew Todd McClintock Memorial Foundation for the study of diseases of the alimentary canal. Volume I. Cloth. Pp. 240, with illustrations. Privately printed. New York, 1925.

Posthumous manuscript of young investigator on timely topic of bacterial mutations.

Allgemeine und spezielle Chirurgie des Kopfes einschliesslich Operationslehre unter besonderer Berücksichtigung des Gesichts, der Kiefer und der Mundöhle. Ein Lehrbuch. Von Eduard Borchers, Professor und Oberarzt der chirurgischen Universitätsklinik Tübingen. Paper. Price, 54 marks. Pp. 382, with 326 illustrations. Berlin: Julius Springer, 1926.

Beautifully printed text on special surgery of the head.

A Further Report on Cancer of the Breast. With Special Reference to Its Associated Antecedent Conditions By Janet E Lane-Claypon, M D, D Sc. Reports on Public Health and Medical Subjects No 32. Price, 3s net Pp. 189. London: His Majesty's Stationery Office, 1926.

Shows that cancer is more frequent in breasts of unmarried women and in those that have nursed insufficiently or too much; also that large majority are diagnosed too late for efficient surgery.

Handbuch der gesamten Augenheilkunde. Von Th. Axenfeld und A Elschnig Lieferung 488 490 I. Teil, I. Band, 2 Abt, Kapital III. Mikroskopische Anatomie der Regenbogenhaut Von M. Wolfrum Paper. Price, 16 50 marks. Pp 218, with 57 illustrations. Berlin: Julius Springer, 1926

New part on histology of the iris, from well established German system of ophthalmology.

Contribution à l'étude des paraplégies pottiques. Essai sur l'evolution et le pronostic, basé sur 40 observations personnelles Par Mme le Dr. Sorrel Dejerine Preface du Dr. Andre Thomas Paper Price, 40 francs. Pp 401, with 98 illustrations. Paris Masson & Cie, 1926

Monographic consideration, surveying literature and discussing forty cases.

Thérapeutique chirurgicale Par P Lecene, Professeur à la Faculte de médecine de Paris, et R. Leriche, Professeur a la Faculté de medecine de Strasbourg Tome III Abdomen et organes génito-urinaires. Par P. Lecene. Cloth Price, 50 francs. Pp. 645. Paris: Masson & Cie, 1926

French textbook of surgery, without a picture.

Indemnity Insurance of Alleged Charitable Hospital

(Levy v. Superior Court of California in and for the City and County of San Francisco (Calif.), 239 Pac. R. 1100)

The District Court of Appeal of California, first district, division 1, says that an action was commenced by one Mae Kilroy Kane against the Mount Zion Hospital, a corporation, and others to recover damages for bodily injuries alleged to have been caused by the negligence of the corporation and its servants in the care and treatment of the plaintiff while a patient in the hospital conducted by the corporation. The corporation denied negligence and as a further defense alleged that it was organized and existed solely for charitable and nonprofit purposes, and that the hospital was operated solely for such purposes. That the plaintiff, desiring to take the deposition of the secretary of the corporation, had a subpena issued requiring his appearance before the court and that he bring a certain policy of indemnity insurance. He appeared as required, but, notwithstanding direction by the court to answer, refused to answer questions asked him as to whether he had brought with him the indemnity insurance policy, and whether the corporation carried a policy which insured it against the consequences of the negligent acts of its employees. He was then adjudged guilty of contempt of court, and thereafter instituted this proceeding to review the judgment of the court, which is annulled, because it is considered that the evidence would not be admissible for any purpose under the pleadings and that therefore the court was without jurisdiction to adjudge him guilty of contempt.

One of the contentions was that, assuming the corporation to be a charity as alleged, the policy in question protected the trust fund against depletion, and that therefore the reason for the rule, if any, exempting the corporation from liability, and based on the fact of the trust fund, failed. But no authorities holding in accordance with the argument of counsel in this behalf were called to the attention of the district court of appeal; and it is this court's opinion that the theory that a charity, not otherwise subject to liability, may become liable by reason of the procurement by those administering it of indemnity insurance cannot be supported in principle

It was further contended that the policy would be admissible as evidence tending to show the character of the corporation and the manner of conducting the hospital. The character of the corporation was to be determined not alone by the powers and purposes defined in its articles of incorporation, but also by the method of transacting the business of the hospital. As a general rule, any facts having rational probative value would be admissible for that purpose; and it was urged that the policy would be relevant as the basis for certain inferences, in that the act of the officers of the corporation in procuring the insurance policy would be evidence of their consciousness that the corporation was not a charity as alleged, and that the hospital was not being conducted for such purposes, but for purposes making necessary or proper the procurement of insurance protecting the corporation from the possible legal consequences of its conduct, and from such consciousness might be inferred the ultimate fact sought to be shown. However, while the evidence offered had indirectly a degree of probative value on the issue as to the character and purposes of the corporation, the ultimate conclusion sought to be drawn therefrom was not the plain or most probable one, and the weight which might fairly be given thereto would not overcome the well settled reasons of policy for the exclusion of evidence of this character; and when the uncertainty as to the rule to be applied to facts such as were alleged in the pleadings mentioned was considered, it appears to the district court of appeal that the act of the corporation in procuring a policy of the character assumed could be the basis for no reasonable inference other than that, as a prudent trustee, in view of such uncertainty, it deemed such protection necessary and proper, pending action by the legislature or a final determination of the question by the courts. The uncertainty referred to the court described as that indicated by the language in *Stewart* v. *Cal. Medical, etc., Assn*, 178 Cal. 418, 423, 176 Pac. 46, which had been cited as authority for the contention that, assuming the allegations as to the character and purposes of the corporation to be true, the rule of exemption from liability for the negligent acts of the employees of a charity has not been adopted as the rule in California, a question with which the court says that it was not concerned at this time.

Putting of Baby in Evidence for Inspection

(Thorne v. State (Ala.), 105 So. R. 709)

The Court of Appeals of Alabama, in affirming a judgment of conviction of defendant Thorne on a charge of seduction, says that the state was permitted, over the objections of the defendant, to make profert of, or put in evidence for inspection, the baby which was alleged to have been born as the result of the alleged seduction. Thus, for the first time, so far as this court could find, was the question of the profert of a baby in a seduction case presented squarely to the court. It is to be conceded that, even in bastardy cases, the authorities are in conflict. But in a bastardy proceeding it has been held in Alabama that it is competent to make profert of the baby, after proper identification, to show resemblance to the reputed father. Still the uncertainty of this character of proof is everywhere conceded, and, but for the Alabama decisions on the subject, this court might be inclined to hold otherwise. Yet, however unsatisfactory it may be, where, as in this case, the question of the paternity of the child becomes relevant for any purpose, the jury should have the benefit of a personal inspection of the child that through the sense of sight the jury may draw its own conclusions as to a resemblance between the defendant and the baby. If there had been no denial of intercourse at the time as testified to by the prosecutrix, a different rule might apply; but in this case the defendant denied the cohabitation, so that, if the child born as a result of intercourse at about the time testified to by the prosecutrix was of such resemblance to the defendant as to impress the jury that the child was the defendant's, such evidence would corroborate the testimony of the prosecutrix and tend to an impeachment of the defendant's statement that he did not have intercourse with the prosecutrix. So that, if the admission of this testimony was technically inadmissible at the time of its admission, it became legal after all the facts had been brought out. Profert of the baby was properly allowed. The child being in evidence for inspection, it was permissible for the solicitor to take it in his arms and exhibit it before the jury. It was also competent to prove by a qualified physician the period of average gestation, which would tend to corroborate the testimony of the prosecutrix as to the intercourse.

Disease as an Accidental Injury—Case of a Cold

(Lerner et al. v. Rump Bros. et al. (N. Y.), 149 N. E. R. 334)

The Court of Appeals of New York, in reversing an order which affirmed an award under the workmen's compensation law, says that the state industrial board found that on June 2 the employee in showing fruit and vegetables to a customer was ten minutes in a refrigerator and received a chill that naturally and unavoidably caused a cold to develop, which lowered his disease resisting power, and, as a result, pulmonary edema and cerebral embolism and septic endocarditis developed and caused his death, November 22. The question was whether, on the facts found, the conclusion could be reached that the employee's death was due to an accidental injury which arose out of his employment within the meaning of the compensation law. Death was due to disease. The disease was not an occupational disease, the natural and unavoidable result of the employment. A distinction exists between accidental injury and disease, but disease may be an accidental injury. The exception arises out of abnormal conditions which must be established to sustain an award. Two concurrent limitations have been placed on the right to recover an award when a disease not the natural and unavoidable result of the employment is developed during the course of the employment, although it does not follow that compensation should be awarded in all cases coming literally within these limitations. First, the inception of the disease must be assignable to a determinate or single act, identified in space or time. Secondly, it must also be assignable to something catastrophic or extraordinary. It has been held in this state that cases of voluntary prolonged contacts resulting in disease are to be excluded from the field of accidental injuries.

In this case a causal connection was sought between the exposure to the cold of the refrigerating plant for ten minutes and the death of the employee as the result. The temperature of the plant must have been less than the freezing point of fruits and vegetables, and the outside temperature was probably not excessive, June 2. The exposure, although occurring at a definite time and place, was not catastrophic or extraordinary. It was like the exposure to drafts when one is heated while at work, or to the change between the cold and wet outside and the warmth inside, which is not infrequently encountered by the workman after coming to his work in inclement weather. Such contacts of the body with the draft or with changes of temperature are natural and normal, and often unavoidable in the conduct of a business. A resulting cold would present itself as a disease and not as an accident.

While it may be difficult to make nice and exact discriminations between disease as an accidental injury and disease which is neither accidental nor an injury in the common acceptance of the terms, it is not difficult to distinguish a case of ordinary exposure resulting in a cold from a case of emergent, prolonged exposure. The definite event here was the change from a hot room to a cold one, as if one should step out of a hot room into the cold in the winter without adequate protection. To call the sequent cold an accidental injury would be to distort the fair meaning of the statute and the underlying principle of compensation cases. The award in this case should be vacated, and the claim dismissed.

Conclusiveness of Expert Testimony

(William Simpson Const. Co. et al. v. Industrial Accident Commission et al. (Calif.), 240 Pac. R. 58)

The District Court of Appeal of California, second district, division 1, in annulling an award of compensation made under the workmen's compensation act for the death of an employee of the construction company who fell from a scaffold about 12 feet from the ground and died about one and one-half hours thereafter, says that the physicians who performed a necropsy the next day found an extensive subdural hemorrhage covering the base and lateral surfaces of the brain, and a basal fracture running across the base of the middle fossa of the skull. The physicians further found a pontile hemorrhage in the brain, which they testified was caused by a stroke of apoplexy, and they gave as their opinion that the stroke preceded and was the cause of the fall, and was therefore the proximate cause of the man's death. The industrial accident commission, however, disregarded the opinion of the medical experts, and found that the fracture of the skull caused by the fall and the subdural hemorrhage from it were the proximate cause of the man's death, and made an award in favor of his dependents. Against this it was contended that the commission was without authority to reject the uncontradicted testimony of the medical experts and to render an award based on a finding that death was due to a cause other than that given therefor by the experts.

In California it has frequently been held that the proper or usual practice and treatment by a physician or surgeon in the examination and treatment of a wound or injury is a question for experts, and can only be established by their testimony. The rule to be drawn from these decisions, as this court understands them, appears to be that whenever the subject under consideration is one within the knowledge of experts only, and is not within the common knowledge of laymen, the expert evidence is conclusive on the question in issue. It follows that in such cases neither the court nor the jury can disregard such evidence of experts, but, on the other hand, they are bound by such evidence, even if it is contradicted by nonexpert witnesses. The same rule would, of course, apply to a proceeding before the industrial accident commission. Under this rule, the commission, in the present proceeding, could not reject the evidence of the medical experts when testifying on any subject peculiarly within their own knowledge. The same rule would apply as to opinions of the medical experts on a subject solely within their professional knowledge, and not within the knowledge of the ordinary individuals.

In this proceeding the evidence of the medical experts as to the condition of the man's skull at the time of the necropsy, and the presence therein of the fracture, and the two hemorrhages, the extent and character of these hemorrhages, and their origin and cause, and their probable effect on the man, and whether they, or either of them, was sufficient to produce death, dealt entirely with matters with which only medical men are familiar, and concerning which they alone could give any intelligent information to the commission. This evidence, being uncontradicted, was binding on the commission, and, according to the foregoing rule, the latter could not reject the same and act on their own knowledge or conclusions But no one saw the man immediately preceding or at the time of the fall There was nothing in the appearance or condition of either hemorrhage to indicate which one occurred *first in point of time The physicians testified that either one* was sufficient to cause death. The only reason assigned for the opinion that the fall was preceded by the stroke of apoplexy was that the pontile hemorrhage was not traumatic. Under all the circumstances, the court thinks that the opinion of the physicians that the stroke of apoplexy occurred prior to the fall was mere conjecture on their part and not based on any evidence warranting such a conclusion, wherefore the commission was not bound by that opinion However, the award made by the commission could not be sustained by this court, because, if the evidence before the commission was insufficient to justify the expert witnesses in concluding that apoplexy was the proximate cause of the man's death, for like reasons it was insufficient to justify a conclusion on the part of the commission that death was due to the fall, uninfluenced and uninduced by the stroke of apoplexy. With the evidence in such a state, any opinion as to the proximate cause of death was a mere surmise and conjecture and not based on any foundation sufficient to support a finding of fact. Hearing denied by supreme court.

Use of Unverified Notes Interpreting Roentgenograms

(Vincent v Otis Elevator Co et al (N Y), 212 N. Y. Supp. 76)

The Supreme Court of New York, Appellate Division, Third Department, on this appeal from an award by the state industrial board of compensation under the workmen's compensation law, tersely says: Award reversed, and matter remitted, with costs against the state industrial board to abide the event, on the ground that the finding that the claimant at the date of the accident was suffering from a tuberculous condition, which became activated by the accidental injury, was based on certain notes interpreting roentgen-ray pictures made by a physician who was not called to verify the pictures or the notes, and was therefore grounded on other than legal evidence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore

75: 533-709 (Feb.) 1926

*Is Vitamin A Secreted Through Skin? Vitamin A in Wool Fat. S. V. Gudjonsson, Copenhagen, Denmark.—p. 533.
*Influence of Testes on Metabolism. E. P. Bugbee and A. Simond, Detroit.—p. 542.
Capillary Pressure in Frog Mesentery as Determined by Micro-Injection Methods. E. M. Landis, Philadelphia.—p. 548.
*Blood Diastases in Depancreatized Dogs. J. Markowitz and H. B. Hough, Toronto.—p. 571.
Effect of Thyroidectomy on Some Unconditioned Responses of Sheep and Goat. H. S. Liddell, Ithaca, N. Y.—p. 579.
Stereoscopic Projection and Ridgway's Standards as Methods of Investigating Color Blindness. T. W. Wingate, H. D. Iler and D. A. Chambers, Cleveland.—p. 591.
Physiology of Sleep. IV. Effect of Sleep on Respiration. C. I. Reed and N. Kleitman, Chicago.—p. 600.
Action of Insulin on Domestic Fowl. G. J. Cassidy, S. Dworken and W. H. Finney, Montreal.—p. 609.
Physiologic Action of Light. VI. Alterations in Cell Electrophoretic Potential Produced by Direct Irradiation of Blood in Vivo. I. S. Falk and C. I. Reed, Chicago.—p. 616.
*Cholesterol and Phosphatide Metabolism in Pregnancy. E. J. Baumann and O. M. Holly, New York.—p. 618.
Cholesterol and Phosphatide Distribution in Some Tissues of Pregnant and Nonpregnant Rabbits. E. J. Baumann and O. M. Holly, New York.—p. 633.
*Effect of Pancreatectomy on Secretion of Succus Entericus. W. Koslowski and A. C. Ivy, Chicago.—p. 640.
Nutrition of White Mouse. H. H. Beard, New Haven, Conn.
  I. Normal Growth and Nutritive Requirements.—p. 645.
  II. Effect of Feeding Diets Rich in Protein and Diets Containing Unbalanced Salt Mixtures. Rôle of Certain Sulphur Components.—p. 658.
  III. Vitamin Factors in Nutrition of Mice.—p. 668.
  IV. Relation Between Diet and Reproduction.—p. 682.
Mineral Metabolism Studies with Dairy Cattle: Mineral Equilibrium During Gestation. H. G. Miller, W. W. Yates, R. C. Jones and P. M. Brandt, Corvallis, Ore.—p. 696.

Vitamin A in Wool Fat.—Argentine wool fat was proved by Gudjonsson not to contain vitamin A. Icelandic wool fat proved to contain vitamin A in rather large quantities. The vitamin A was destroyed on heating. It is thought probable that vitamin A is secreted through the skin.

Influence of Testes on Metabolism.—Experiments made by Bugbee and Simond with a castrated male dog failed to show that castration in itself reduces the basal metabolic rate. Other factors to be considered are lack of psychic stimulation, lack of muscular exercise, adaptation of the nervous system and endocrine gland system to a life calling for less metabolism than in an active normal life.

Blood Diastases in Depancreatized Dogs.—No facts were elicited by Markowitz and Hough which would justify the employment of blood diastase estimations in clinical diabetes.

Cholesterol and Phosphatide Metabolism in Pregnancy.—The lipoidemia of human pregnancy is explained by Baumann and Holly as a reaction similar to those called forth by any intoxication, and reasons for the different findings in man and the rabbit are suggested.

Effect of Pancreatectomy on Succus Entericus.—Koskowski and Ivy assert that total pancreatectomy does not materially affect the quantity of the secretion of succus entericus. The invertase content is definitely increased from three to seven days, but fluctuates, and then there is a tendency for it to return to a level slightly above normal. Total pancreatectomy causes a temporary decrease in the amylase content of succus entericus, but has no effect on the lipase content. For the first eighteen days following pancreatectomy, no compensatory changes occur in the secretion of succus entericus which would facilitate intestinal digestion.

American Journal of Roentgenology and Radium Therapy, New York

15: 1-92 (Jan.) 1926

Dosage Study Relative to Therapeutic Use of Unfiltered Radion. G. Failla, F. Adair, E. H. Quimby, K. Sugiura, C. Arnell and W. Goldsmith, New York.—p. 1.
Treatment of Epithelioma of Penis with Radium and Roentgen Rays. A. L. Dean, New York.—p. 36.
Malignant Tumors of Testis. E. L. Keyes, New York.—p. 44.
Complete Insulation Versus Grounding as Protection Against High Tension Electric Shocks. W. F. Hemler, Washington, D. C.—p. 49.
*Roentgen-Ray Study of Bronchiectasis. J. J. Singer and E. A. Graham, St. Louis.—p. 54.
*Secondary Evidence of Gallbladder Disease. W. W. Belden, New York.—p. 58.
*Demonstration of Bronchial Tree by Intratracheal Injections of Lipiodol. H. W. Grady, Washington, D. C.—p. 65.
New Devices for Implantation and Removal of Radium Needles. H. Wachtel, Cracow, Poland.—p. 76.

Drainage for Bronchiectasis.—Singer and Graham advise that postural drainage be instituted in bronchiectatic cases after the first plate is taken. Subsequent plates will give information as to the relative size of the bronchiectatic area.

Secondary Evidence of Gallbladder Disease.—The importance of the findings of indirect signs of gallbladder disease are emphasized by Belden. He says that no gallbladder examination is complete without a roentgenoscopic examination of the stomach and duodenum and a roentgenographic examination when possible, because the filling defects caused by adhesions and pressure from a distended gallbladder very markedly increase the percentage of diagnosis of gallbladder disease.

Lipiodol in Lung Examinations with Roentgen Ray.—Grady has used lipiodol for the purpose of demonstrating bronchiectasis and lung abscess. The intercricothyroid route was used in all cases. Roentgenograms are made immediately after the injection. The greater part of the lipiodol is eliminated by coughing within a few hours after the injection. The remainder gradually disappears, usually in from one to two weeks. In one case a small amount remained in the lung four months after the injection. No immediate or late ill effects of any importance have been observed.

American Review of Tuberculosis, Baltimore

13: 97-191 (Feb.) 1926

*Vital Staining in Experimental Tuberculosis. R. H. Jaffe, Chicago.—p. 97.
Reaction and Growth Curves of Cultures of Tubercle Bacilli. R. R. Henley, Washington, D. C.—p. 107.
*Unsuccessful Attempts to Cure or Prevent Tuberculosis in Guinea-Pigs with Dreyer's Defatted Antigen. M. Nevin, F. R. Bittman and E L Hazen, New York.—p. 114.
*Latent Tuberculosis in Childhood. VI. F. Eberson, San Francisco.—p. 124.
Extrapleural Thoracoplasty. L. S. Peters, Albuquerque, N M.—p 149.
*Artificial Pneumothorax. A. Swezey and A. Schonbar, Denver.—p. 156.
Accidental Pneumothorax Complicating an Attempt to Induce Artificial Pneumothorax. S. Simon, Denver.—p. 168
Metallic Sound. H. M. Kinghorn, Saranac Lake, N. Y.—p. 175.

Vital Staining in Experimental Tuberculosis.—Jaffe asserts that most intensive vital staining of rabbits with india ink or colloidal iron does not prevent the formation of tubercles. This observation is not in accordance with the possibility of a functional elimination of cells by the granular storage of foreign material. The decrease of the dye in the growing tubercle, and its absence under certain conditions in larger tubercles, does not result from a diminished vitality of the epithelioid cells, but is due to the lack of proper circulation.

Dreyer's Defatted Antigen in Tuberculosis.—The defatted antigen prepared according to Dreyer's method failed to show either therapeutic or prophylactic benefit when injected by Nevin and his associates into tuberculous guinea-pigs. On the contrary, animals treated with the vaccine died earlier than the untreated controls.

Latent Tuberculosis in Childhood.—One hundred and forty-five cases of juvenile tuberculosis have been studied by Eberson with regard to history, age groups, symptomatology, physical and roentgen-ray findings and tuberculin reactions. It would appear that pulmonary foci are frequently overlooked. The pulmonary foci were found in 46.5 per cent of the patients in this study, and of these, 71.6 per cent showed calcification of the focus or of the adjacent intrapulmonary lymph nodes Peribronchial tuberculosis of the nature of definite pathologic changes or adjacent to bronchial ramifications was demonstrated by the roentgen ray in 5 per cent of the cases Mediastinal adenopathy of clinical significance could be shown with the aid of lateral roentgenograms There was a complete correlation between positive tuberculin tests and clinical and roentgen-ray findings, which warranted the diagnosis of latent or active tuberculosis Quantitative intracutaneous tests with bovine and human tuberculins demonstrated the following 73 per cent reacted more violently or solely to bovine tuberculin, 26 per cent reacted more strongly to human tuberculin, and 1 per cent reacted to human tuberculin only Lymphangitis accompanying tuberculin tests occurred in three additional cases Interpretation of the test depends on the kind of tuberculin used, and a test is of value only when made with derivatives of tuberculin which contain an active principle that is as yet not clearly determined Quantitative comparable results can be obtained by the use of highly graduated dilutions of different types of tuberculin when these have been standardized previously Eberson believes that the value of a positive tuberculin test in the presence of adenopathy cannot be doubted if it be remembered that the self same diseases of childhood which may cause nonspecific adenopathy are known to "extinguish" tuberculin reactions

Artificial Pneumothorax—The data obtained by Swezey and Schonbar from a study of 207 cases of artificial pneumothorax are not considered convincing enough to justify definite conclusions as to the indications and contraindications for artificial pneumothorax treatment The best results were obtained in cases in which a successful collapse was secured with the contralateral lung only slightly involved, and which were free of serious complications interfering with the nutrition of the patient such as enteritis or active laryngitis Advanced lesions in the "good' lung contraindicate the treatment As to all the cases, while the balance of evidence seems to be slightly in favor of the treatment, yet considering especially the frequency of complications resulting from this treatment in such cases, it is probably best not to be too optimistic about it unless the treatment becomes imperative for the purpose of controlling hemoptysis A reasonable trial should be given first to other forms of immobilization, such as strict bed rest, posture treatment or the chest belt

- Epilation in Mice as Biologic Standard for Determining Roentgen Ray Dosage H H Hazen and L C Milstead Washington, D C —p 230
- *Intravenous Administration of Sulpharsphenamine in Syphilis M F Lautman Hot Springs Ark —p 234
- *Ultraviolet Light Treatment of Roentgen Ray Telangiectases C G Lane, Boston —p 237

Parasite in Creeping Eruption—Five microscopic nematode parasites have been recovered by Kirby-Smith, Dove and White, from serial sections of skin tissue excised from patients with creeping eruption This is the first recovery of the nematode from lesions of creeping eruption It has been given the name *Agamonematodum migrans* by the authors Cases in persons most extensively infested have originated underneath buildings when men at work were wet with perspiration and were in contact with the damp sandy soil Minor infections have often occurred in children playing in low areas where apparently surface drainage had disseminated the parasites The inability to locate the parasite definitely has much to do with the difficulty experienced in treatment When the parasite has invaded the sole or the palm, the difficulty is increased Ethyl acetate applied on cotton or gauze or used in a flexible collodion has been effective in many cases Refrigeration with ethyl chloride, carbon dioxide snow, or crushed ice with salt has been used successfully

Physical Allergy as Cause of Dermatoses.—Physical allergy is a name suggested by Duke for altered reaction caused specifically by the action of physical agents such as light, heat, cold and mechanical irritation, and in the case of heat sensitiveness, indirectly by the effect of mental or physical exertion The reactions produced are of two varieties (1) contact reactions and (2) reflex-like reactions The cutaneous symptoms vary with the degree of sensitiveness of the patient and with the intensity of the exposure

Cutaneous Reaction in Leishmaniasis—Intradermal injections of an alkaline extract of *Leishmania* were given by Montenegro to thirty-seven patients with leishmaniasis, and positive reactions were obtained in thirty-two of them, or 86 5 per cent Injections with the same extract were also given to thirty-six persons free from leishmaniasis Of these, thirty three developed negative reactions, and three showed a certain reaction definitely distinct from the specific reactions obtained with the patients who had leishmaniasis

Bismuth Salicylate in Syphilis—The results of Gruhzit's experimental work lead him to conclude that bismuth salicylate possesses high spirocheticidal power and causes no pain or irritation at the site of injection, its rate of absorption appears to be better than that of metallic suspensions and is equal to that of tartrobismuthates

Gastric Acidity in Acne Vulgaris—Twenty-five patients with acne vulgaris, varying in duration, type and severity, were examined by Knowles and Decker for total and free hydrochloric acidities by the fractional gastric analysis method Ten cases showed a total acidity below 50, seven between 50 and 60, four between 60 and 70 and the remaining four above 70 The acid values apparently had no relation to the duration, type or severity of the condition Patients with a low acidity were improved when given a mixture containing dilute hydrochloric acid

Intramuscular Absorption of Insoluble Bismuth Compounds.—The findings of Cole et al indicate that injections of metallic bismuth are dangerous and if persisted in will lead to cumulative absorption and possibly even to fatal results The same is probably true, although to a lesser extent, of bismuth oleate Bismuth salicylate, likewise, is not above this objection and its use should be replaced by one of the more soluble bismuth salts—perhaps the potassium-bismuth tartrate preparations These salts, especially if injected intragluteally, once a week are probably not so likely to give rise to cumulative action However, the patient should be observed closely as even this salt is not above criticism so far as its absorption is concerned The contention that insoluble bismuth salts must be injected twice weekly, in the authors' opinion is open to question, as only a small amount of the salt will be absorbed, at the most Moreover, too frequent deposits may lead to cumulative action, toxic symptoms and even the death of the patient

Sulpharsphenamine Intravenously in Syphilis—Very good results are reported by Lautman from the use, intravenously, of sulpharsphenamine In cases of syphilis which are Wassermann-negative and free from clinical symptoms, sulpharsphenamine seems quite as capable of controlling the disease as the older arsenicals In neural syphilis sulpharsphenamine is even more effective than arsphenamine or neoarsphenamine Given intravenously, sulpharsphenamine did not produce dermatitis and caused practically no constitutional reactions Lautman says that on account of the absence of disagreeable reactions patients submit more willingly to treatment with sulpharsphenamine, and, consequently, it is indicated in cases in which the maximum spirocheticidal effect of arsphenamine and neo-arsphenamine is not essential

Ultraviolet Ray Treatment of Roentgen-Ray Telangiectases—One case in point is reported by Lane His experience prompts him to recommend that a proper dosage, three and one-half to four and one-half minutes, or enough to produce flaccid vesiculation, should be used, that proper intervals both between areas treated and dates of treatment be observed, and that areas of telangiectases without marked atrophy and not too large can be benefited by ultraviolet ray treatment. The seriousness of traumatizing tissue already atrophic and degenerative by reason of an agent with a somewhat shorter wave length must be borne in mind, and the treatment should be undertaken with great caution, with a full knowledge of the abnormal tissue which is being treated, and with great care to prevent infection of the bullae and erosions produced by treatment.

Archives of Surgery, Chicago

Twenty-Eighth Report of Progress in Orthopedic Surgery. R. B. Osgood *et al.*—p. 604.

Operation for Umbilical Hernia.—The usual transverse elliptic incision is made by Stone surrounding the umbilicus and carried down to the anterior sheath of the rectus muscles all around. The neck of the sac is isolated, the sac opened, and its contents dealt with as conditions may require to secure reduction. Then the sac and skin immediately about the umbilicus are excised, leaving only a narrow margin of peritoneum about the hernial orifice. This orifice is not enlarged, but is closed by mattress sutures of strong silk or catgut so as to convert the oval or round orifice into a straight transverse line of closure. The second row of sutures is also a series of interrupted mattress stitches, overlapping the first row, which they bury, and forming another transverse line of closure over the first. The span of each of these stitches is about 1 cm. wider than the first row of stitches, so that when they are tied an inverted buttress of anterior sheath, about 1 cm. in depth, is turned inward over the first layer of closure. The point of especial emphasis is that this second row of sutures begins well laterally to each end of the first row, which simply closed the hernial orifice.

Coxa Vara: Etiology.—Noble and Hauser are of the opinion that there is considerable evidence that the pituitary gland plays an important part in this disease, and that trauma plays a minor part.

Gaucher's Disease.—Two new cases of Gaucher's disease are reported by Cushing and Stout. There was a considerable proportion of the cerebrosid kerasin in the spleen of one of these patients. This confirms the work of Lieb and Epstein. It seems reasonable to suppose that this substance is contained within the cytoplasm of the Gaucher cells. It has been demonstrated that the presence of the large cells in the bone marrow of the head and neck of the femur may result in a marked destruction of bone and produce a chronic osteoarthritis with sequestrum formation. Of the various types of treatment attempted, splenectomy is the only one that has been attended with any measure of success. The authors feel that there is no indication that the disease is cured by this procedure. It is their opinion that enough evidence does not exist to show that splenectomy actually prolongs life, although the figures suggest that it may. In the majority of cases, splenectomy does not result in an amelioration of symptoms; the general health and strength improve, and the tendency to bleed is diminished.

Fibrosarcoma of Thyroid.—The case described by Zeckwer was one of fibrosarcoma of the thyroid gland which showed rapid growth, involving the recurrent laryngeal nerve and producing massive metastases in the lungs. Proof of the *fibroblastic origin of the tumor was offered by the demonstration* of fibrils by histologic methods.

Boston Medical and Surgical Journal

194: 381-424 (March 4) 1926

Present Status of Effect of Organ Extracts on Control of Blood Pressure. W. J. MacDonald and T. C. Burnett, Boston.—p. 381.
*Cancer in Massachusetts. J. H. Nichols, F. W. Goodhue, M. E. Champion, G. H. Bigelow and H. L. Lombard, Boston.—p. 388.
*Etiology of Congenital Club Foot. C. Bearse, Boston.—p. 394.

Cancer in Massachusetts.—In compliance with a legislative resolve, the departments of public health and public welfare of Massachusetts made an investigation in 1925 on the cancer situation in Massachusetts. The significant findings were: cancer is on the increase, but there are indications that the peak of the curve may be nearly reached. Massachusetts had the highest death rate of any state in the union. The proportionate mortality for cancer among inmates of almshouses and insane institutions is lower than among the general population *of the same age distribution. The cancer rate increased with* density up to a population of about 4,000 per square mile. From there it remains nearly stationary. The cancer rate increases from west to east in Massachusetts. The average duration of life for patients operated on for cancer who die of cancer is 22.8 and for patients not operated on, 20. The average duration from onset to operation is 10.3 months. The average patient comes to a doctor eight months after first noticing symptoms. About one fourth of all cancer deaths occur in hospitals, but the length of stay in hospitals is too short to be considered adequate. The hospitals are increasing their share of the cancer load. There is need for additional beds for cancer cases as well as for all chronic diseases. Quacks are not a large factor in the inoperable cancer problem in Massachusetts. Further education of the public as to early diagnosis and treatment is necessary.

Etiology of Clubfoot.—The case cited by Bearse shows that it is possible to have a club foot deformity without any intra*uterine conditions entering into it.* The fetus was estimated to be 14 weeks old and had a single clubfoot.

Iowa State Medical Society Journal, Des Moines

26: 55-100 (Feb.) 1926

Diagnostic Net: Medical Viewpoint. F. G. Murray, Cedar Rapids.—p. 55.
*Treatment of Pernicious Anemia with Mercurochrome. P. B. McLaughlin, Sioux City.—p. 58.
Hydronephrotic Kidney. R. L. Latchem, Sioux City.—p. 60.
Perinephritic Abscess. R. H. Lott, Carroll—p. 62.

Ophthalmology and General Practitioner. J. S. Reynolds, Minneapolis.—p. 86.
Urea as Therapeutic Agent, Especially Postoperative. R. L. Fenlon, Clinton.—p. 87.

Mercurochrome in Treatment of Pernicious Anemia.—During the last eighteen months, McLaughlin has treated fourteen cases of pernicious anemia with intravenous injections of mercurochrome-220 soluble. He states positively that he can produce remissions in the disease more quickly, and that these remissions are more lasting, than with any other treatment. The patients apparently regain their strength and enjoy life. Some of them have taken up their former vocations, and by conserving energies and being more prudent in their ways of living, are now able to earn a livelihood. He is positive that the disease is an infection, the primary infection being a glossitis. McLaughlin's treatment consists of giving intravenously a 1 per cent solution of mercurochrome, in from 15 to 30 cc. doses, every three to five days. Improvement first manifests itself in a very marked increase of appetite, the patient seemingly not being able to get enough to eat. Most of the patients have had the disease two or more years. The majority of them have had blood transfusions a number of times. All have had iron and arsenic by mouth; some have had subcutaneous or intravenous injections of these drugs. Under this treatment the patients gradually grew worse, and most of them were very low in red blood cells and hemoglobin, when they entered the hospital for treatment.

Effect of Administration of Calcium and Sodium Salts on Metabolism.—Greenwald says that the administration of calcium salts to thyroparathyroidectomized dogs led, at first, to a deposition of a large part of this calcium in the tissues, chiefly as calcium phosphate Later, calcium equilibrium was attained A parathyroidectomized dog receiving a liberal supply of calcium had a normal concentration of calcium in the serum and was resistant to the administration of sodium phosphate (50 mg of phosphorus per kilogram of body weight) as were normal dogs Later, when the supply of calcium was diminished, the concentration of calcium in the serum was much less, and the injection of the same amount of phosphate was followed by tetany It is suggested that the calcium content of the plasma is, normally, maintained at a constant level by an equilibrium between inorganic calcium and an organic compound of calcium. Resemblances between this organic compound and calcium citrate are indicated, but the substances are not identical It is suggested that the parathyroid hormone is necessary to the preparation of this organic constituent The implications of this hypothesis are discussed.

Fate of Ingested Creatine.—Evidence is presented by Chanutin to indicate that creatine has an indirect action on nitrogen metabolism The absorption of creatine from the alimentary tract appears to be complete. There is no evidence of its bacterial destruction in the alimentary tract. The creatinine content of the urine in man increases after ingestion of large doses of creatine Data are presented to prove that extra creatine excretion is derived directly from the creatine fed.

Effect of High Protein Diet on Kidney.—By feeding very high protein diets for from ten to twenty months, about a third of a rat's life, Jackson and Riggs have been unable to produce in these animals any recognizable nephritis

Acid-Base Equilibrium of Plasma.—Peters et al. state that there is a general tendency for protein, bicarbonate and chloride to reciprocate in their changes and to aid one another in maintaining the total acid and total base at a constant level

Disturbance of Electrolyte Equilibrium.—It is suggested by Peters et al. that any given disturbance of electrolyte equilibrium will evoke a train of reactions and changes in all the other electrolytes. These reactions always tend to restore equilibrium. The response is not directed toward the maintenance of the concentration of any single constituent or group of constituents, but will be manifested to a greater or less degree in one or the other according as it may best serve to restore the equilibrium and maintain the functional *automatism of the whole organism.*

Thiasine in Blood.—In pig and human blood the thiasine is contained wholly in the corpuscles. Benedict, Newton and Behre have determined the thiasine content of nearly 200 human bloods Results show a thiasine content averaging from 14 to 15 mg. per hundred cubic centimeters of blood for a large group of unselected hospital and ambulatory cases The highest figures have been obtained in diabetic cases, *many of which show from 20 to 27 mg of thiasine per hundred* cubic centimeters of blood In nephritis, on the contrary, the tendency is to normal or unusually low figures.

Comparison of Blood Sugar Tests.—Four different methods of determining blood sugar values have been compared by Duggan and Scott. The Folin-Wu and Hagedorn methods were found to be accurate and fairly precise when used to determine the concentrations of pure glucose solutions *approximating those encountered in blood analysis.* It was found that an increase in the concentration of either the sugar or of the picric acid in the Benedict method would lead to high results, and this is offered as at least a partial explanation of the high results obtained by this method in certain pathologic bloods The Shaffer-Hartmann method was found to be reliable and satisfactory for concentrations above about 25 mg per hundred cubic centimeters of blood. Certain corrections also appear to be *necessary to their table* A substitute table is submitted.

Radical Treatment of Trigeminal Neuralgia.—In treating trigeminal neuralgia, Sachs has extracted the posterior root of the gasserian ganglion in seventy-one operations, without a death In forty-two cases alcohol injections were given. In the vast majority of cases the patients are satisfied and tremendously pleased with the relief they have obtained. A few find the numbness or paresthesia annoying, but this is so rare that Sachs has no hesitation in recommending this procedure for the treatment of major trigeminal neuralgia

Aberrant Thyroid.—Guazon reports a case of aberrant thyroid and two cases of papilloma of the thyroid

Sodium Citrate as Hemostatic.—Sison and Ignacio regard sodium citrate as one of the most powerful and effective hemostatics, especially in arresting inaccessible hemorrhages. They have used from 20 to 30 cc of a 30 per cent sodium citrate solution, previously sterilized, and from 1 to 2 cc. of a 0.5 per cent solution of procaine. Hot water bags must be applied over the place of the injection to minimize the pain and, if need be, some morphine may be administered. While they have given intravenous injections, the intramuscular route is preferred.

Iodine in Treatment of Hyperthyroidism.—Compound solution of iodine was used by Thomas and Rienhoff in the treatment of thirty cases of exophthalmic goiter. After the patients had received this solution for three or five days, the restlessness and nervousness became less marked, the tremor diminished and in many the skin was less flushed. In most cases the maximum results were obtained in from five to fourteen days. In three cases the maximum result was not obtained until between the twenty-first and twenty-fifth day. The basal metabolic rate decreased in all of the cases, varying from 11 to 72 per cent, an average fall of 34 per cent. In 50 per cent of the cases, the rate was reduced to normal. In 33 per cent of the cases the basal metabolic rate was reduced to below 40 per cent above normal, and in 6 per cent the reduction was so slight that rest in bed alone might account for it. In most instances when the patients were operated on their basal metabolic rate was not more than plus 30 per cent.

Angina Pectoris.—Philip's discussion of angina pectoris is based on a study of the literature and on the personal observation of 179 cases. The clinical history is fully reviewed and treatment is outlined. Philips believes that operative treatment should be limited to that extremely small group of cases in which the paroxysms of anginal pain recur so frequently as to make life unendurable.

Gastric Acidity.—Comparisons made by Silverman and Denis of their colorimetric method with the scientifically accurate electrometric determinations have shown the former to be correct within hundredths of a degree.

Treatment of Chorea.—The results of treatment of sixty-two cases of chorea are described by Dwyer. Magnesium sulphate, in 25 per cent solution, given intramuscularly, has a definite sedative action in the majority of cases. Typhoid vaccine, containing from 20 to 40 million killed typhoid bacilli in each dose, is often beneficial in the long continued mild case or the case in which the most marked symptoms have disappeared and some residual chorea persists. The autoserum therapy has given good results in the few instances in which it was tried. Horse serum, intrathecally, as advocated by Porter, gave good results in a few instances and no results in many others. Chorea serum furnished by Rosenow produced no appreciable benefit. Relieving intracranial pressure by spinal puncture was not found beneficial, although it was not tried in enough patients to give it a fair estimate of its value. Neo-arsphenamine was without any benefit. The use of salicylates is thought to be beneficial only when there is evidence of an active rheumatic infection, and chloral and bromides are often necessary as sedatives in the severe cases.

Muscle Reeducation in Anterior Poliomyelitis.—Hatch avers that muscle reeducation given after all pain and sensitiveness has subsided, and by fully trained associates, is the greatest aid in the treatment of anterior poliomyelitis. Overuse of the weak muscles must be guarded against carefully. The use of as little apparatus as possible is urged.

Treatment of Acute Peritonitis.—For draining the ileum and to introduce fluids into the rectum, Harbin uses an intestinal aspirator of corkscrew shape.

*Bilateral Renal Aneurysm. F. H. Healy.—p. 374.
*Case of Pernicious Anemia. D. B. Sutton.—p. 374.

Gastric Pain.—Miller says that the visceral pain of indigestion is to be attributed to the condition and the behavior of the muscular wall of the stomach.

Nephrectomy in Infant.—Morson reports a case of nephrectomy for hydronephrosis in an infant, aged 7 months. The kidney was abnormal. It had two ureters, one leaving the kidney at the usual location, the other leaving from the upper pole. There was no communication between the two pelves. The two ureters united just before entering the bladder.

Bilateral Renal Aneurysm.—In the case cited by Healy, aneurysms were found on both renal arteries. The right renal artery was tortuous and presented a firm swelling, the size of a tangerine orange, at the entrance of the hilum. Three swellings, the size of peas, were present on subdivisions of the artery. The left renal artery had tumors in the same position, but on a slightly smaller scale. It was evident that the aneurysmal dilatation of the renal vessels was a sequel to arteriosclerotic changes. Examination of the heart showed marked concentric hypertrophy of the left ventricle, and atheroma of the coronary arteries. The brain showed sclerosis of all arteries, particularly of the basal. Three hemorrhagic sites were present: the oldest, the size of a walnut, in the right internal capsule; the intermediate, the size of a Spanish nut, in the left internal capsule; and the most recent, the size of a walnut, just anterior to the genu of the left internal capsule.

Atypical Pernicious Anemia.—Sutton records a case of pernicious anemia in which the erythrocytes numbered only 300,000 per cubic millimeter; leukocytes, 23,200; hemoglobin, 8 per cent, color index, 1 2 The duration of the disease was only twelve weeks Many of the classic physical signs were not present

Splenectomy for Splenic Anemia in Children —Ashby and Southam draw attention to the possibility of treating cases of splenic anemia in young children by the removal of the spleen and record three cases so treated after medical and roentgen-ray treatment had been found unsatisfactory All the patients have recovered and appear greatly benefited by the operation

Osteomalacia in Kashmir —Vaughan says that osteomalacia is exceedingly common in Kashmir Almost all Kashmir women who have borne children are affected in some degree, with the exception of the boatman class These women live in the open air on large freight boats, work hard and feed with the men They are too poor to cook their food much, and eat raw cucumbers tomatoes, etc, with their rice The worst cases are seen in the houses of the wealthy, who keep their women in seclusion and among those of the poorer classes who do the same Many deaths take place in childbirth owing to conditions consequent on osteomalacia, and as skilled assistance is not available, mother and child are often lost Rickets is not common in Kashmir

Lead Colloids in Treatment of Cancer.—Coke and Cook detail their experiences with lead in the treatment of twenty cases of inoperable cancer One of the preparations used, a very stable colloidal suspension of lead and mercury containing 0 1 per cent each of mercury and lead, has given the best results However, these results were, on the whole, in no wise different from those obtained by others with other forms of treatment—good, bad and indifferent

Treatment of Tic Douloureux —Mills prefers alcohol injections to operation in the treatment of these cases Out of every four cases three patients have been reasonably comfortable with injection and one has needed open operation

Iodine Treatment of Actinomycosis —From 5 to 10 minims of iodine in half a cup of milk, three times a day, has proved ample to effect a cure in the four cases of actinomycosis reported by Chitty

Blood Pressure of Chinese —The blood pressure of over 700 Szechwanese students was taken by Kilbourn The mean systolic and diastolic pressures were lower than the standards for Anglo-Saxons of corresponding ages The pulse pressure, on the other hand, was as high as that of the white races The mean for 741 students was systolic, 111 mm, diastolic, 70 mm, and pulse pressure, 42 mm Systolic and diastolic pressures of nine Canadian and American boys (mean age, 15), born and brought up in Szechwan, were markedly higher than those of the Chinese, but pulse pressure was about the same The mean pressures found were systolic, 120 mm; diastolic, 80 mm, and pulse pressure, 40 mm The records show no marked variation of blood pressure with age, within the limits investigated Systolic and diastolic pressures vary with body weight, but the pulse pressure shows no constant variation

Incidence of Appendicitis Among Chinese.—Of 815 bodies examined by Gibson eighty-one showed no evidence of recent or old inflammation of the appendix, and eight were affected with tubercular disease, secondary to abdominal tuberculosis The appendix is often congested in diseases such as beriberi, dysentery and pneumonia, but these were not included unless other evidence of appendicitis was present The milder types of appendicitis are common among Chinese, but the majority of those do not come to the hospital for treatment Relatively few cases of the suppurative or gangrenous types occur, but in the larger cities most of those are brought to the hospital

Dermoid Cysts in Young Girls —Pendleton's patients were aged 12 and 13 years, respectively In the second case, the ovarian tumor showed no sign of malignancy, nor did the surrounding structures contain any tumors, but in the urethra, at the meatus, was a metastatic tumor which proved to be a carcinomatous dermoid cyst The tumor recurred after removal by the patient's father It grew rapidly Pendleton removed it radically, but inasmuch as the patient disappeared from view no further report of her subsequent condition can be made

Acute Lymphatic Leukemia —This disease is very rare in Korea The chief points of interest in Cate's case were an acute onset and fulminating course, bleeding from the gums, intestines, nose into the skin and finally into the meninges The mucosa of the mouth was gangrenous The lymphocyte count was 320 000, unusually high At the end, violent central nervous system symptoms developed, then coma and death

Use of Mercurochrome in Typhoid —In eight cases of typhoid in children, Koo has injected 1 per cent aqueous solution of mercurochrome intravenously with good result Moderate doses, 0 003 Gm per kilogram of body weight, did not produce any reaction The temperature fell by lysis The drug was seen in the urine, stools and vomitus within a few hours after injection Widal tests became negative within forty eight hours The dose may be repeated, if necessary Koo is convinced that the drug shortens the duration of the disease

Case of Acute Fatal Medinal Poisoning F Stolland —p 391
*Unexpected Maternal Deaths Occurring During Parturition and Early in Puerperium J St G Wilson and E Glynn —p 392

Rôle of Mesentery in Visceral Disorders —Gray is of the opinion that the mesentery receives too little attention in the study of visceral disease In the health of the gastro-intestinal tract (and in the symptoms of disease of that tract), the mesentery is the first consideration A great part of abdominal surgery should be directed toward the protection from damage of so vital a structure as the mesentery, whether by infection or mechanical trauma In the latter instance, a large group of disorders arise primarily from visceroptosis, whether local or general Treatment in such cases should always be directed toward protection of the mesentery from undue strain

Radiotherapy for Rodent Ulcer. — Hernaman-Johnson regards radiotherapy as the treatment of election for "virgin" rodent ulcers In the case of a recurrence, rays of a different wave length from those originally used should be employed If improvement is not manifest within a month, some method of resensitizing the tissues, as by curettage or ionization, should be resorted to, after which radiation may again be given a trial If the foregoing methods are not producing definite and continuous improvement at the end of two months, the diathermic cautery should be employed. If all recurrences are dealt with promptly, there should be no need for surgery in the ordinary sense of the term. When, however, the recurrence has already assumed large proportions, it may be necessary to invoke the aid of the plastic surgeon to make good what has been destroyed.

Unexpected Maternal Deaths.—Wilson and Glynn report two cases: In one, death occurred during parturition from acute streptococcal septicemia following the induction of premature labor, and in the second case death occurred early in the puerperium due to delayed chloroform poisoning.

Diverticulitis and Its Surgical Treatment. J. P. Lockhart Mummery.—p 437
Glycosuria in Acromegaly. K S Hetzel—p. 440.

Radiotherapy of Operable Breast Cancer.—In the series of cases reported by Webster et al., every patient either refused operation, or else age, chronic bronchitis, heart disease, or glycosuria made operation inadvisable. The interim results suggest that such patients should be offered the alternative of radiation treatment more freely than they are at present; at least, they should not be told that there is no alternative to operation.

Standardization of Tuberculin and Precipitin Test.—Okell and six others report on the result of a joint investigation made by them as to whether tuberculins found to be equal (within the error of the test) to standard by the official Frankfort test on guinea-pigs could vary widely in their content of the active principles of "tuberculin," the substance used for the detection of tuberculosis in man and animals. Their findings may be summarized as follows: The precipitation test does not necessarily measure the active principles of tuberculin on which its use in the various methods of diagnosis of tuberculosis depends. Satisfactory agreement in precipitin unit value was obtained by two different groups of workers by the precipitin test. This test apparently measures with a considerable degree of accuracy a substance probably other than the active principle of tuberculin, and presumably the interesting precipitable substance of Mueller and Laidlaw. The "tuberculin" value of tuberculins which have been standardized by the official Frankfort method can not in all cases be deduced from the precipitin test. The results obtained by subcutaneous, intracutaneous, and Pirquet tests on guinea-pigs and by the tests on tuberculous human beings and cows were in agreement. By these three methods a tuberculin of standard strength and two others of values approximately 10 and 5 per cent of standard were placed correctly in order of merit

Rupture of Thoracic Aorta.—In the case cited by Sheldon and Dyke rupture of the aorta occurred through an atheromatous plaque. The patient died nine days after the accident The atheromatous condition of the aorta in this case was apparently a part of the diffuse disease of the intima of the vasculature, which is always associated with "primary chronic interstitial nephritis" Fatty change of the intima of the smaller vessels was a marked feature in microscopic sections of the kidney, and the spleen, the only other organ examined. Syphilis was definitely excluded in this case.

Encephalitis Following Operations on Temporal Bone J. A Jones—p. 493.

Treatment of Epilepsy, Neurosyphilis and Disseminated Sclerosis.—Buzzard discusses the treatment of epilepsy, syphilis of the nervous system, and disseminated sclerosis, and lays emphasis on two principles which are of outstanding importance if any measure of success is to be attained. The first of these is early diagnosis associated with a frank recognition of the fact that preventive measures must be the mainstay in the struggle against the diseases under review. The second principle is that of taking courage in both hands and, in spite of the public demand for rapid cures, insisting on regulated treatment over long, perhaps indefinitely long, periods of time.

Associated Organisms Causing Empyema.—In the case reported by Boldero and Whitby, two organisms were associated in its production, the one a mycelium and the other a pneumococcus. Alone, neither was pathogenic to guinea-pigs, but in association they always produced lesions Clinically, the striking feature of the case was its chronicity. Probably the start of the empyema can be dated from an attack of pneumonia, which occurred five months before the patient came under observation.

Toxicity of Carbon Tetrachloride in Treatment of Ankylostomiasis M Khalil—p 547
*Operative Treatment of Carbuncle A Edmunds—p 548

Treatment of Malignant Disease with Lead.—Bell and his associates report on the results of the treatment of *227* cancer patients with lead They believe that all types of malignant growths are probably amenable to the beneficial influence of lead, provided the metal can reach the malignant cells in sufficient quantity Adjuvant surgical and radiologic measures in suitable circumstances may be employed with considerable advantage When the growth has been partly, or apparently entirely, removed, intravenous injections of lead should be employed within a few days of the operation when possible The method of treatment is difficult, and to some extent dangerous, and can only be employed safely by those who are thoroughly experienced in the work and have laboratory facilities at their disposal

Treatment of Carbuncle.—Edmunds makes a crucial incision, dissects up the flaps, cuts away all suppurating tissue and packs the resulting cavity with cyanide gauze wrung out in 1.40 phenol. Thus, the whole area is opened up to the maximum extent, but with this advantage, four flaps of skin have been left—a little irregular and ragged perhaps—but capable of being replaced in a few days The saving of the skin in no way hinders the drainage, while it accelerates healing very much and diminishes the size of the ultimate scar.

*Water Snails of Monaro and New South Wales Cercaria Carrying Capacity B Bradley—p 147
Encephalitis. H H Marshall and K Inglis—p 159
*Staining of Intercellular Substance. J. M Petrie—p 163

Snails Carry Flukes.—Bradley found that a certain species of snails (*Limnoca brazieri*) showed a high percentage rate of infestation with fluke embryos, probably carrying several types. He is convinced that this snail is the transmitting agent of the sheep fluke in New South Wales.

Staining of Intercellular Substance.—It has been demonstrated by Petrie that the intercellular material forming the semifluid "ground substance" in certain endothelial tissues can be stained and made visible. This is due to the presence of a potassium compound in the intercellular cement substance Fresh tissue is laid on a slide and treated with cobalt. After a certain time the slide is washed with ice-cold water till the excess of reagent is completely removed If the slide is now examined under the microscope, the intercellular substance is seen to be formed of yellow precipitate, which is the triple salt of cobalt sodium potassium nitrite; when the preparation is subsequently treated with ammonium sulphide, this yellow compound is changed to black cobalt sulphide, which is permanent.

8 per cent; color index, 1.2. The duration of the disease was only twelve weeks. Many of the classic physical signs were not present.

Splenectomy for Splenic Anemia in Children.—Ashby and Southam draw attention to the possibility of treating cases of splenic anemia in young children by the removal of the spleen, and record three cases so treated after medical and roentgen-ray treatment had been found unsatisfactory. All the patients have recovered and appear greatly benefited by the operation.

Osteomalacia in Kashmir.—Vaughan says that osteomalacia is exceedingly common in Kashmir. Almost all Kashmir women who have borne children are affected in some degree, with the exception of the boatman class. These women live in the open air on large freight boats, work hard and feed with the men. They are too poor to cook their food much, and eat raw cucumbers, tomatoes, etc., with their rice. The worst cases are seen in the houses of the wealthy, who keep their women in seclusion, and among those of the poorer classes who do the same. Many deaths take place in childbirth owing to conditions consequent on osteomalacia, and as skilled assistance is not available, mother and child are often lost. Rickets is not common in Kashmir.

Lead Colloids in Treatment of Cancer.—Coke and Cook detail their experiences with lead in the treatment of twenty cases of inoperable cancer. One of the preparations used, a very stable colloidal suspension of lead and mercury containing 0.1 per cent each of mercury and lead, has given the best results. However, these results were, on the whole, in no wise different from those obtained by others with other forms of treatment—good, bad and indifferent.

Treatment of Tic Douloureux.—Mills prefers alcohol injections to operation in the treatment of these cases. Out of every four cases, three patients have been reasonably comfortable with injection and one has needed open operation.

Iodine Treatment of Actinomycosis.—From 5 to 10 minims of iodine in half a cup of milk, three times a day, has proved ample to effect a cure in the four cases of actinomycosis reported by Chitty.

Blood Pressure of Chinese.—The blood pressure of over 700 Szechwanese students was taken by Kilbourn. The mean systolic and diastolic pressures were lower than the standards for Anglo-Saxons of corresponding ages. The pulse pressure, on the other hand, was as high as that of the white races. The mean for 741 students was: systolic, 111 mm.; diastolic, 70 mm., and pulse pressure, 42 mm. Systolic and diastolic pressures of nine Canadian and American boys (mean age, 15), born and brought up in Szechwan, were markedly higher than those of the Chinese, but pulse pressure was about the same. The mean pressures found were: systolic, 120 mm.; diastolic, 80 mm., and pulse pressure, 40 mm. The records show no marked variation of blood pressure with age, within the limits investigated. Systolic and diastolic pressures vary with body weight, but the pulse pressure shows no constant variation.

Incidence of Appendicitis Among Chinese.—Of 815 bodies examined by Gibson eighty-one showed no evidence of recent or old inflammation of the appendix, and eight were affected with tubercular disease, secondary to abdominal tuberculosis. The appendix is often congested in diseases such as beriberi, dysentery and pneumonia, but these were not included unless other evidence of appendicitis was present. The milder types of appendicitis are common among Chinese, but the majority of those do not come to the hospital for treatment. Relatively few cases of the suppurative or gangrenous types occur, but in the larger cities most of those are brought to the hospital.

Dermoid Cysts in Young Girls.—Pendleton's patients were aged 12 and 13 years, respectively. In the second case, the ovarian tumor showed no sign of malignancy, nor did the surrounding structures contain any tumors, but in the urethra, at the meatus, was a metastatic tumor which proved to be a carcinomatous dermoid cyst. The tumor recurred after removal by the patient's father. It grew rapidly. Pendleton removed it radically, but inasmuch as the patient disappeared from view no further report of her subsequent condition can be made.

Acute Lymphatic Leukemia.—This disease is very rare in Korea. The chief points of interest in Cate's case were an acute onset and fulminating course; bleeding from the gums, intestines, nose, into the skin and finally into the meninges. The mucosa of the mouth was gangrenous. The lymphocyte count was 320,000, unusually high. At the end, violent central nervous system symptoms developed, then coma and death.

Use of Mercurochrome in Typhoid.—In eight cases of typhoid in children, Koo has injected 1 per cent aqueous solution of mercurochrome intravenously with good result. Moderate doses, 0.003 Gm. per kilogram of body weight, did not produce any reaction. The temperature fell by lysis. The drug was seen in the urine, stools and vomitus within a few hours after injection. Widal tests became negative within forty-eight hours. The dose may be repeated, if necessary. Koo is convinced that the drug shortens the duration of the disease.

Case of Acute Fatal Medinal Poisoning. E. Stolkind.—p. 391.
*Unexpected Maternal Deaths Occurring During Parturition and Early in Puerperium. J. St. G. Wilson and E. Glynn.—p. 392.

Rôle of Mesentery in Visceral Disorders.—Gray is of the opinion that the mesentery receives too little attention in the study of visceral disease. In the health of the gastrointestinal tract (and in the symptoms of disease of that tract), the mesentery is the first consideration. A great part of abdominal surgery should be directed toward the protection from damage of so vital a structure as the mesentery, whether by infection or mechanical trauma. In the latter instance, a large group of disorders arise primarily from visceroptosis, whether local or general. Treatment in such cases should always be directed toward protection of the mesentery from undue strain.

Radiotherapy for Rodent Ulcer. — Hernaman-Johnson regards radiotherapy as the treatment of election for "virgin" rodent ulcers. In the case of a recurrence, rays of a different wave length from those originally used should be employed. If improvement is not manifest within a month, some method of resensitizing the tissues, as by curettage or ionization, should be resorted to, after which radiation may again be given a trial. If the foregoing methods are not producing definite and continuous improvement at the end of two months, the diathermic cautery should be employed. If all recurrences are dealt with promptly, there should be no need for surgery in the ordinary sense of the term. When, however, the recurrence has already assumed large proportions, it may be necessary to invoke the aid of the plastic surgeon to make good what has been destroyed.

Unexpected Maternal Deaths.—Wilson and Glynn report two cases: In one, death occurred during parturition from acute streptococcal septicemia following the induction of premature labor, and in the second case death occurred early in the puerperium due to delayed chloroform poisoning.

Glycosuria in Acromegaly. K. S. Hetzel.—p. 440.

Radiotherapy of Operable Breast Cancer.—In the series of cases reported by Webster et al., every patient either refused operation, or else age, chronic bronchitis, heart disease, or glycosuria made operation inadvisable. The interim results suggest that such patients should be offered the alternative of radiation treatment more freely than they are at present; at least, they should not be told that there is no alternative to operation.

Standardization of Tuberculin and Precipitin Test.—Okell and six others report on the result of a joint investigation made by them as to whether tuberculins found to be equal (within the error of the test) to standard by the official Frankfort test on guinea-pigs could vary widely in their content of the active principles of "tuberculin," the substance used for the detection of tuberculosis in man and animals. Their findings may be summarized as follows: The precipitation test does not necessarily measure the active principles of tuberculin on which its use in the various methods of diagnosis of tuberculosis depends. Satisfactory agreement in precipitin unit value was obtained by two different groups of workers by the precipitin test. This test apparently measures with a considerable degree of accuracy a substance probably other than the active principle of tuberculin, and presumably the interesting precipitable substance of Mueller and Laidlaw. The "tuberculin" value of tuberculins which have been standardized by the official Frankfort method can not in all cases be deduced from the precipitin test. The results obtained by subcutaneous, intracutaneous, and Pirquet tests on guinea-pigs and by the tests on tuberculous human beings and cows were in agreement. By these three methods a tuberculin of standard strength and two others of values approximately 10 and 5 per cent of standard were placed correctly in order of merit.

Rupture of Thoracic Aorta.—In the case cited by Sheldon and Dyke rupture of the aorta occurred through an atheromatous plaque. The patient died nine days after the accident. The atheromatous condition of the aorta in this case was apparently a part of the diffuse disease of the intima of the vasculature, which is always associated with "primary chronic interstitial nephritis." Fatty change of the intima of the smaller vessels was a marked feature in microscopic sections of the kidney, and the spleen, the only other organ examined. Syphilis was definitely excluded in this case.

Encephalitis Following Operations on Temporal Bone. J. A. Jones.—p. 493.

Treatment of Epilepsy, Neurosyphilis and Disseminated Sclerosis.—Buzzard discusses the treatment of epilepsy, syphilis of the nervous system, and disseminated sclerosis, and lays emphasis on two principles which are of outstanding importance if any measure of success is to be attained. The first of these is early diagnosis associated with a frank recognition of the fact that preventive measures must be the mainstay in the struggle against the diseases under review. The second principle is that of taking courage in both hands and, in spite of the public demand for rapid cures, insisting on regulated treatment over long, perhaps indefinitely long, periods of time.

Associated Organisms Causing Empyema.—In the case reported by Boldero and Whitby, two organisms were associated in its production; the one a mycelium and the other a pneumococcus. Alone, neither was pathogenic to guinea-pigs, but in association they always produced lesions. Clinically, the striking feature of the case was its chronicity. Probably the start of the empyema can be dated from an attack of pneumonia, which occurred five months before the patient came under observation.

*Operative Treatment of Carbuncle. A. Edmunds.—p. 548.

Treatment of Malignant Disease with Lead.—Bell and his associates report on the results of the treatment of 227 cancer patients with lead. They believe that all types of malignant growths are probably amenable to the beneficial influence of lead, provided the metal can reach the malignant cells in sufficient quantity. Adjuvant surgical and radiologic measures in suitable circumstances may be employed with considerable advantage. When the growth has been partly, or apparently entirely, removed, intravenous injections of lead should be employed within a few days of the operation when possible. The method of treatment is difficult, and to some extent dangerous, and can only be employed safely by those who are thoroughly experienced in the work and have laboratory facilities at their disposal.

Treatment of Carbuncle.—Edmunds makes a crucial incision, dissects up the flaps, cuts away all suppurating tissue and packs the resulting cavity with cyanide gauze wrung out in 1:40 phenol. Thus, the whole area is opened up to the maximum extent, but with this advantage, four flaps of skin have been left—a little irregular and ragged perhaps—but capable of being replaced in a few days. The saving of the skin in no way hinders the drainage, while it accelerates healing very much and diminishes the size of the ultimate scar.

Encephalitis. H. H. Marshall and K. Inglis.—p. 159.
*Staining of Intercellular Substance. J. M. Petrie.—p. 163.

Snails Carry Flukes.—Bradley found that a certain species of snails (*Limnoca brazicri*) showed a high percentage rate of infestation with fluke embryos, probably carrying several types. He is convinced that this snail is the transmitting agent of the sheep fluke in New South Wales.

Staining of Intercellular Substance.—It has been demonstrated by Petrie that the intercellular material forming the semifluid "ground substance" in certain endothelial tissues can be stained and made visible. This is due to the presence of a potassium compound in the intercellular cement substance. Fresh tissue is laid on a slide and treated with cobalt. After a certain time the slide is washed with ice-cold water till the excess of reagent is completely removed. If the slide is now examined under the microscope, the intercellular substance is seen to be formed of yellow precipitate, which is the triple salt of cobalt sodium potassium nitrite; when the preparation is subsequently treated with ammonium sulphide, this yellow compound is changed to black cobalt sulphide, which is permanent.

*Diabetes Insipidus of Syphilitic Origin. L. Babonneix and J. Lhermitte.—p. 471.
*Treatment of Lesions in Infundibulopituitary Region. G. Levy.—p. 479.

Functions of the Infundibulotuberal Region and Its Relations with the Pituitary.—This entire issue of the *Annales* is devoted to tuberal syndromes. A full summary was given in the Paris Letter in The Journal, March 27, 1926, p. 964. Lereboullet emphasizes that the trophic disturbances in the bones are the most solidly established facts to date for which the pituitary can be incriminated. In the adiposogenital syndromes, and obesity of alleged pituitary origin, pathologic conditions in the hypothalamus probably cooperate more or less extensively. Diabetes insipidus in a woman who had died from cancer of the pleura and lung was explained by syphilitic changes involving the infundibulum, tuber cinereum and the stalk of the pituitary, while the pituitary itself was intact. The lesions thus were not glandular but in the nervous apparatus. Levy discusses treatment of lesions in this region; organotherapy is a useful adjuvant, but treatment as for syphilis should always be given a thorough trial, she insists, under ophthalmoscopic control. The latter should be the guide also for surgical measures or radiotherapy, and extreme caution should be the watchword. The condition of the optic nerve is the criterion.

18: 753-832 (Dec.) 1925

Intraventricular Conductibility and the Electrocardiogram. C. Pezzi.—p. 753.
Angina Pectoris from Projectile. E. Doumer.—p. 766.
*Heart Derangement in an Athlete. P. Meyer.—p. 772.

Functional Heart Block in Trained Athlete.—Meyer reports a case of this kind in a medical student devoted to out-of-door sports, especially skiing. He had taken part in several contests. He had never noted any signs of heart disturbance during strict physical training, and the consecutive fatigue. Nothing abnormal was revealed on clinical and roentgen-ray exploration of the heart. Nevertheless electrocardiograms showed retarded auriculoventricular conduction, the conduction time being almost twice as long as normal. Under the effect of exercises and atropine, the heart block disappeared entirely, thus testifying to the functional nature of the changes of rhythm. Evidently the heart disorder was caused only by physical strain, similar to another phenomenon noted in athletes, namely, nodal bradycardia.

Hemohistioblasts in Myeloid Leukemia. J. Sabrazes.—p. 38.

Changes of Arterial Pressure After Ramisection.—Leriche and Fontaine observed a change in the arterial pressure after ramisection in fifteen cases in the last year. The operation consisted in severing the rami communicantes of the stellate ganglion and intermediary ganglion (when there was one). A transient increase of arterial tension appeared only on the operated side, and was soon followed by hypotension. On the other hand, there was always considerable rise of the oscillometer index on both sides, reaching its maximum in one or two days, and persisting for a few days. These phenomena can be explained only by the existence of centripetal nerves in the vascular adventitia—real pressor nerves controlling the arterial tension. Stimulation of them causes hypertension; severing them induces hypotension. The occurrence of vasomotor reflexes on both sides is probably due to the existence of only one vasomotor center in the medulla oblongata. The return of the arterial tension to normal, within a certain time after the operation, may be ascribed to the fact that the vascular tonus is thereafter regulated only by the centripetal fibers of the intact side.

Multiple Heart Disturbances in Acute Articular Rheumatism.—Doumer reports a case of febrile rheumatism associated with nodal bradycardia, retarded auriculoventricular conduction and auricular extrasystoles. The peculiar changes of the heart rhythm suggested that the interstitial nodules of the rheumatic myocarditis had affected the nerves of the heart more than the myocardium itself.

*Cancer a Hundred Years Ago. P. Menetrier.—p. 177.
*Artificial Immunization Against Tuberculosis. A. Calmette et al.—p. 182.

Cancer at Paris in 1826.—Menetrier compared the hospital cancer records at Paris and in Switzerland in the first quarter of the last century with those of the current year, and was amazed to find the average about the same: 14 per cent of all deaths over the age of 15 in 1825, and 10-12 per cent of all deaths in his Paris hospital service in recent years.

Vaccination of the New-Born Against Tuberculosis with BCG.—Ninety-four Paris infants inoculated with BCG vaccine in 1921-1922 were under supervision in 1925. Calmette and his co-workers state that all are healthy and developing normally, although seventeen of them were born and raised by tuberculous mothers. In the whole of France about 5,183 new-born infants were inoculated with BCG emulsion in the last six months of 1924. Of 1,317 infants supervised for six to eighteen months, 586 were exposed to tuberculous contamination. Among them, 7.2 per cent have died from nontuberculous diseases, and 1.8 per cent from presumed tuberculosis. While the minimal mortality among nonvaccinated infants exposed to contamination, during the first year of life, is at least 25 per cent, certain French statistics show a mortality of 32.6 per cent or more. Of 117 infants inoculated with BCG vaccine in Belgium, ninety-two have been under regular observation. None of them have died from a presumed tuberculous affection, although forty-six were born and remained in a tuberculous environment. In French Indo-China, 3,352 native new-born infants were inoculated; and in French occidental Africa, 218. All are perfectly healthy. It appears that immunity from this vaccine, as revealed by the resistance to reinfection, lasts over three years. Five years' experience has demonstrated that inoculation with BCG vaccine is harmless, they say, and they advise its use as a prophylactic measure, especially in families in which the new-born are exposed to contagion. They reiterate that it must be applied within the first ten days of life. (This method of vaccination against tuberculosis with living bacilli was described in an editorial, Feb. 27, 1926, p. 626. It was also mentioned later, March 6, page 724.)

*Action of Vagus in Hyperglycemia. Papilian and Funariu.—p. 159.

Relations Between Herpes Zoster and Chickenpox.—Netter and Urbain examined the serum of 100 subjects with herpes zoster and twenty-four with chickenpox, using the crusts for antigen. The crossed and homologous complement fixation tests were positive in 93 per cent in herpes zoster; and in 91.7 per cent in chickenpox. The amount of antibodies was minimal the first days of the eruption, maximal within the second week, but they persisted sometimes for as long as eighteen months. Crusts of chickenpox and of herpes were used in cases with herpes or chickenpox; or either of the crusts alone. The behavior of the antigen and antibodies was identical in all. Six cases of herpes zoster seemed to be responsible for development of chickenpox in persons who had been in contact with them. In two instances, zoster developed in a chickenpox focus. In eight cases, herpes zoster accompanied chickenpox. It seems that the chickenpox virus inducing herpes has passed through a kind of mutation, analogous to that of the smallpox virus in relation to vaccinia. Owing to the mutation, it acquires certain properties. Thus in herpes the virus is more resistant than in chickenpox. While in chickenpox the virus disappears rapidly, in herpes it may persist inactive for a long time. Then, under the influence of various causes as, for instance, arsenical poisoning, the herpes virus may regain its activity and induce the zoster eruption.

The "Associated Vaccines."—Ramon and Zoeller injected 1 cc. of TAB vaccine—a mixture of typhoid and paratyphoid A and B vaccines—with 0.5 cc. of diphtheria anatoxin for the first injection, and with 1 cc. for the second, eighteen days later. Tests were made in subjects with a positive or negative Schick reaction. The results showed that addition of TAB vaccine does not affect the formation of diphtheria antitoxin in the blood serum. The same was evident with injections of TAB vaccine plus tetanus anatoxin. First 2 cc., and then 2.5 cc. of the associated vaccines were injected, with a fifteen days' interval; a third injection (1 cc.) was given eight days later. Then 1 cc. of the serum from these subjects neutralized from 1,000 to 3,000 lethal doses, and even more. No impairment in formation of tetanus antitoxin was noted from association of tetanus anatoxin with the diphtheria anatoxin. Ramon and Zoeller say that these experiences seem to open the field for simplified procedures in vaccination.

Chloroform Sensitization of Medulla for Cocaine.—Intravenous injections of cocaine were made in dogs, under chloroform. It was evident, Bardier and Stillmunkès say, that the chloroform had enhanced the susceptibility of the bulbar centers to the cocaine.

Acid-Base Balance of the Blood in Epilepsy.—Dautrebande's research seems to confirm the presence of an alkaline substance in the blood in epileptics. It has no affinity for carbon dioxide in vivo. This agrees with Bisgaard, Jarloev and Noervig's findings; they also noted in epilepsy the presence of an abnormal product of metabolism, giving an alkaline reaction.

Influence of Epinephrine, Atropine and Pilocarpine on Metabolism.—Papilian and Bendescu's observations were made on patients with mild eye diseases. They emphasize that epinephrine exaggerates the basal metabolism, while atropine checks it. Therefore stimulations of the sympathetic and parasympathetic system may only increase the basal metabolism.

Action of Vagus in Hyperglycemia.—Papilian and Funariu conducted experiments on dogs. Severing the vagus nerves prevented the appearance of glycemia from epinephrine and pilocarpine. Evidently the vagus may be partly responsible for an increase of sugar in the blood.

*Primary Tumors of Bones. P. A. Huet.—p. 1.
*Cancer of Undescended Testicle. L. Aurousseau.—p. 17.

Treatment of Primary Tumors of Bones.—Analysis of the ultimate outcome in thirty cases testifies that conservative measures, including resection, should be the rule for benign tumors in bones (chondromas, myeloplax or fibroid tumors and fibrocystic osteitis). Malignant tumors in bone call for amputation, and the criterion for the malignancy is not local recurrence—this may occur with a benign tumor—but metastasis at a distance, reproducing the structure of the primary tumor. If amputation is refused, the radiologist should be called in. Huet adds that the results from radiology cannot be worse than those from conservative measures for cancer of the bone.

Cancer of the Undescended Testicle.—Aurousseau summarizes seventy-six cases on record. He calculates that 10 per cent of cancers of the testicle affect the ectopic organ while there is only one testicle out of a thousand that is not in the scrotum. The ages ranged from 17 to 52. Only forty-four were given thorough operative treatment. Of the nineteen cases in which the ultimate outcome is known, there was recurrence in ten, but nine were known to be in good health from three months to eleven years later. In seventeen cases the cancer was discovered only at necropsy.

*Rupture of the Bladder During Cystoradiography. J. Rejsek.—p. 382.
*Urologic Congress Proceedings.—p. 388.

Resection of Perineum for Urethral Stenosis.—Bazy refers to Horteloup's method for treating gonorrheal strictures in cases with complications. The technic is generally known as the Albarran-Heitz-Boyer procedure. He describes its successful application in an extremely complicated case of long standing, and reviews forty-six analogous nontuberculous cases treated by various operative measures. The main point is to remove all the pathologic tissues, not leaving a trace of fibroid tissue, as sclerosis testifies to infection. Even the most attenuated infection is liable to be roused to virulence by the operation, and hence all sclerotic tissue must be eradicated. Simple edema of course should be respected; the swelling subsides after removal of all infected tissue. He sutured around the retention catheter, without preliminary diversion of the urine. On the other hand, he usually diverts the urine in treating traumatic strictures, when there is a prospect of suturing the stumps of the urethra smoothly together.

Rupture of the Bladder During Roentgen Examination.—Rejsek injected 120 cc. of the contrast suspension into the bladder of a robust man, aged 68, who had complained of bladder symptoms only for three months. The injection was made gently and was followed by an intense contraction of the bladder, but the severe pains persisted only for a short time after evacuation of the bladder. The roentgenogram revealed that the bladder had ruptured in the reaction to the injection. The opaque fluid formed a crescent above the bladder, but there was no extravasation of blood, and no trace of the rupture could be found in the bladder although considerable urine had escaped into the surrounding tissues. This was wiped out and the patient dismissed in two weeks. He succumbed to acute pneumonia not long after.

Urologic Congress.—The topic appointed for discussion was high diversion of the urine.

Malaria in Syria. A. Gemayel.—p. 219.

Lipiodol in Diagnosis and Treatment of Tuberculous Serositis.—Direct injections of iodized oil were made by Fiessinger and Lemaire in five cases of hydropneumothorax, one of pyopneumothorax, one of purulent pericarditis, and one of tuberculous peritonitis with hypertrophy of the liver. They used light and heavy lipiodol (0.11 and 0.44 Gm. of iodine per cubic centimeter). First 5 cc. of the light was injected, then 5 cc. of the heavy. The injection was sometimes repeated three or four times, at fifteen or twenty days intervals. The roentgenograms showed then exactly the location of the effusion and its volume. The injections were valuable in diagnosis of interlobular or intrapulmonary effusions. No results were obtained in large pleural effusions; but a medium serofibrinous pleuritis and a small hydropneumothorax of the phrenicocostal sinus soon disappeared after the lipiodol injection. The latter corrected also the diagnosis, which had escaped the roentgen ray and puncture. Remarkable results were noted in a case of tuberculous pericarditis; three injections of lipiodol induced considerable improvement of heart weakness, subsidence of dyspnea, and resorption of the effusion. A second injection on recurrence was followed by a similar effect, postponing the inevitably fatal outcome. The method is contraindicated in progressing tuberculosis, in which lipiodol seems to favor the spread of the lesions.

*Latent Syphilis and Pregnancy. E. Bertin.—p. 278.
Medical Impressions of Three Years in Paraguay. C. André.—p. 283.

Latent Syphilis and Pregnancy.—Bertin discusses the reactivation of latent syphilitic infection under the influence of a pregnancy. The latent syphilis is graver for the fetus than for the mother. Under successive abortions the infection may become attenuated. The Wassermann test, previously negative, may become positive during pregnancy, and again negative after childbirth. Localization of the spirochetes in the pelvic organs during pregnancy may induce a relative immunity. Thus may be explained the gradual attenuation of syphilitic infection, evident in repeated pregnancies. After a series of abortions, the women frequently give birth to fully developed infants with only slight traces of congenital syphilis. This may occur even if the women are not treated.

*Eunuchoid Adiposogenital Dystrophy. N. Schereschewsky.—p. 395.
*Ovarian Insufficiency, Melanoderma and Mental Disturbance. E. Bonilla.—p. 408.

Eunuchoid Adiposogenital Dystrophy.—A case is described in detail which combines various features of the Frölich type and of the eunuchoid type of adiposogenital dystrophy. The latter seems to be always a pluriglandular affection; in this case a severe infectious disease at the age of 8 (severe headache predominating in the clinical picture) was evidently a factor in the nondevelopment of the gonads. Before that the child had been apparently normal in every respect. Implanting of a testicle from another man (undescended testicle) at the age of 22 has failed to modify the condition in any way during the eight months to date.

Ovarian Insufficiency, Bronzing and Psychic Disturbances.—Bonilla has encountered eight cases of the syndrome described by Block in 1916, and he discusses melanoderma in general as connected with the endocrines and with sexual development. In the Block syndrome, the bronzing is undoubtedly the result of ovarian insufficiency without participation of the suprarenals. The ages ranged from 28 to 52, and there was in all a history of grave infectious disease or loss of property or unfortunate love affair or conjugal discord. The husband of one was impotent. None of the women had had for years or ever a normal sexual life, and Bonilla is inclined to accept a tendency to a premature menopause in some of the women. He remarks that the sexual function is one of the best stimulants of the genital internal secretions; it acts as a kind of auto-organotherapy. Hyperthyroidism was noted in only one of these patients, but ovarian insufficiency was pronounced in every case. In one, an injection of epinephrine induced an intense reaction, but Marañon has demonstrated that this is not pathognomonic for hyperthyroidism. The blood pressure and the cholesterol and glucose content of the blood testified against suprarenal involvement. Under ovarian treatment marked improvement was almost constantly realized; the pigmentation retrogressed more or less and the nervous symptoms subsided. He combined belladonna or thyroid treatment with the ovarian extract in some cases.

Weakness in Power to Grow and Congenital Dwarfism.—Jansen asserts that when growth does not proceed normally, this is due to deleterious influences affecting the growing tissues, impairing their growing power, and that the degree of checking of the growth is determined by the rate at which the tissue was growing. This is the law of the vulnerability of cells that are growing rapidly. He explains how these principles throw light on the connection between rickets, achrondroplasia and other disturbances. What he calls weakness of growth entails excessive sensitiveness and readiness to fatigue. It appears first in muscles, as the muscles grow most rapidly at first. In the bones, the more rapidly growing parts are affected first. He gives photographs of a number of large families showing the effect on the growth of the children, of different injurious influences to which they were subjected at different ages. Unusually tall adolescents, children with genua valga, rickets, marasmus or pedatrophia represent the four main degrees of weakness of growth. In the mildest form it induces merely exceptional sensitiveness, so that growth is stimulated to excess. The male glands are especially sensitive; Jansen suggests that tobacco poisoning in the father may influence the growth of children born later.

Infectious Jaundice.—Mikulowski relates that in the last quarter of 1924 he encountered thirty-four cases of infectious jaundice in children at Warsaw. The onset was abrupt, with high fever, and the liver was large and painful in 80 per cent. The jaundice persisted for a week to a month but the course was mild on the whole. Contagion was evident.

Local Immunity in Mumps.—Cramer treated a case of mumps localized exclusively in the sublingual glands. The boy, aged 16, had had mumps three years before, involving the parotid and submaxillary glands and accompanied by orchitis. Apparently these glands, vaccinated by the first attack of mumps, were refractory to the second infection. As the parotids and submaxillaries were thus immune, the mumps virus attacked the sublingual glands which it usually invades only exceptionally. Cramer considers this case as a demonstration of local immunity, induced by direct contact of the virus with receptive cells of the glands.

Present Status of Prophylactic Serotherapy of Measles and Whooping Cough. P. Gautier.—p. 52.

Pathogenesis of Hepatolenticular Disease.—Mahaim created a biliary fistula in dogs and then injected alcohol in the biliary ducts, thus attacking directly the hepatic cells. Two of the animals died thirty-one and seventy-nine days later, with symptoms of progressive jaundice. Histologic examination revealed generalized lesions of brain cells, in the cortex as well as in the central nuclei. There were moreover vascular and neuroglia lesions confined exclusively to the central nuclei. The excessive fragility of these vessels and necrosis of the central nuclei suggest that the brain is not affected first in Wilson's disease, but secondarily to the liver. The vessels of the gray substance seem to be peculiarly susceptible to the still unknown, but probably different agents, and this may be responsible for the lesions in pseudosclerosis, parkinsonism, possibly also in chorea, Parkinson's disease and the lesions recently described by Steck.

Exploratory Excision in Cancer.—Ludwig regards the exploratory excision or curettement in carcinoma patients as exceedingly dangerous. He explains by this the generalization of apparently radically removed small tumors. Even the introduction of radium needles into the tumor is dangerous. Only in doubtful cases, and only when everything is ready for the operation, is exploratory excision permissible.

Irradiated Milk.—Hottinger confirms the antirachitic qualities of milk (human or cow's) irradiated with ultraviolet rays. The concomitant anemia is not influenced as long as the children are overfed with milk.

Biology of the New-Born.—Hellmuth investigated the lipoids of the serum and of the erythrocytes in pregnancies and in the new-born. Cholesterol and its esters, lecithin and fatty acids of the serum increase in pregnancy. Cholesterol esters occurred in the erythrocytes in twelve of thirty pregnant women. The toxemia of pregnancy had no characteristic influence. He found—contrary to others—esters of cholesterol in every specimen of blood taken from the umbilical vein. The infant has the maximum concentration in lipoids in the whole blood, the mother in the serum.

Trichomonas Vaginalis.—Schmid and Kamniker consider the trichomonas as pathogenic. A yellow discharge and considerable itching are the clinical symptoms. Lavage with a 0.1 per cent solution of mercuric chloride, followed by drying of the vagina and swabbing it with cotton dipped in 10 per cent borax-glycerol, is recommended. This treatment is repeated every other day for one week and twice in the second week. Vaginal suppositories containing 2 Gm. of 10 per cent borax-glycerol are introduced on the days without lavage.

Cause of Tubal Pregnancy.—Schoenholz concludes from his investigations that previous inflammation of the tube is seldom responsible for tubal embedding of the ovum. In most of the cases it is due to diverticula, in some to loosemeshed folds in the mucous membrane, and in some, perhaps, to the presence of cytogenic tissue in the tube.

Acetonuria in Pregnancy.—Kleesattel finds that pregnant women need more carbohydrates for utilization of fat than other subjects. He attributes this to a change of liver function, due to the endocrine action of the placenta and corpus luteum. He advises restriction of fat and proteins in the diet, especially in toxicoses.

Vaccine Therapy.—Finkelstein discusses the question of vaccine treatment in children. He is quite skeptical: "An injection of vaccine the day before the crisis happens to arrive gives excellent results in lobar pneumonia." He quotes a few papers showing lack of autocriticism. In spite of this, he has seen good results in infections which possess a tendency to spontaneous healing. Gonococcus arthritis and conjunctivitis, and certain cases of acute pyodermia are suitable for it. He injects 500 millions of colon bacilli intramuscularly, and increases the dose rapidly if it fails to produce a local or general reaction. He saw a few surprising results with intravenous injections in typhoid, but a grave collapse observed in one of the successful cases caused him to discontinue the intravenous method. Children—except the tuberculous—usually stand more vaccine than adults. He strictly denies the value of vaccine treatment in pneumonia and whooping cough, and doubts it in pyelitis.

Female Sex Hormone.—Loewe, Lange and Faure state that when administering the female sex hormone by mouth to castrated animals, twenty-fold larger doses were required than with subcutaneous injections. Without regard to the species, the dose required was, so far, proportional to the weight of the animals tested.

Haff Disease.—The opinion of the faculty members of the University of Königsberg, published in this report, is opposed to the theory of direct poisoning with volatile arsenical compounds. Some of them believe that eels caught at a certain place were toxic. The mud taken from the spot induced a similar disease in young cats.

Oxygen Inhalation in High Altitudes.—Stern found in healthy and tuberculous subjects a tremor when they came to high altitudes. Administration of oxygen reduced it. The time of reaction to auditory stimuli is prolonged at the high altitudes. Oxygen shortened it in health. In some of the tuberculous subjects, oxygen prolonged it. The hardness of the muscles increased with high altitudes. After inhalation of oxygen, it increased further in the healthy but decreased in many tuberculous patients.

The Reticulo-Endothelial System and Poisons.—Händel and Rosenzuaig removed the spleen in some mice, and supplemented this in others with intravenous injection of colloidal iron oxide. These animals reacted to strychnine and quinine practically no more than the controls. With injections of cocaine, the splenectomized mice—especially those with splenectomy plus blocking of the reticulo-endothelium apparatus—reacted much more severely than the controls.

Complications in Prostatectomy.—Schwarz emphasizes the importance of preparation for prostatectomy—especially of a preliminary suprapubic fistula. He waits until the kidney function improves.

Chemotherapy of Infections.—Saxl, Donath and Kelen were able to protect rabbits against an otherwise lethal staphylococcus infection by preliminary intravenous injections of acriflavine or other drugs, or by oral administration of acriflavine or scarlet red

Athletic Sports, the Heart and the Action of Drugs.—Kauf found that subcutaneous injection of 1 mg. of atropine does not increase the pulse frequency in persons taking part in various sports The pulse reaction to epinephrine was normal. He concludes that the vagus-accelerans equilibrium is shifted toward the vagus side by its preponderance.

Influence of the Vegetative Nervous System on Carbo- rate Metabolism.—Mirtovsky's experiments were con- ted on dogs, cats and rabbits Excitation of the vagus ve was applied in fifteen animals, and the nerve was evered in thirteen The results showed that the vagus has no direct influence on carbohydrate metabolism. The hyperglycemia following stimulation of the vagus is a psychic phenomenon, due to vegetative reflexes in the centers and sympathetic system Decrease of glycemia after division of the vagus may be explained by gradual failing of the animal, and extinction of its vital motor functions. Severing the vagus in parathyreoprival tetany and experimental pancreatic diabetes did not modify the content of glucose in the blood Removal of the striate bodies induced prolonged hyperglycemia analogous to that in diabetes mellitus or experimental pancreatic diabetes Division of the vagus had no action on it. Hyperglycemia, following excision of the striate body, is induced chiefly by the glycogen of the liver, and probably without participation of the suprarenal secretion. Severing the splanchnic nerves prevented hyperglycemia after removal of the striate body. It appears that only the sympathetic system plays an active part in regulating the glucose content of the blood

*Tuberculous Meningitis in an Infant P. Muntendam, Jr —p 20.
Puerperal Fever Merging into a Psychosis A de Groot —p 22
*"Autostasis" and Medicine F M G de Feyfer —p 27.

Psychasthenic Depression Versus Melancholia.—Breukink remarks that all persons with a neurosis are trussed up in a harness, bound by all kinds of remembered and dreaded things. But the depression is, as it were, superposed, and the only way to remove it is by influencing the mind. All other therapeutic measures merely fasten the inferiority complex more firmly. On the contrary, the patient must be impressed with the idea that he does not need supports and props Another point emphasized is the necessity for treating both man and wife when one has a neurosis, as the other is almost certain to be more or less affected. The environment must be instructed as to the way in which to respond to the patient's complaints; the constant pressure from the environment is a very potent factor in the aggravation or cure.

The Heart in Epidemic Encephalitis.—In four of the five selected cases the arrhythmia was pronounced, while in the fifth case the heart action was merely extraordinarily sluggish. Palpitations were one of the earliest symptoms of epidemic encephalitis in Hanneman's experience, and frequently gave the clue to the nature of the disease in the milder cases.

Appendekthlipsia.—Geesink has coined this term to designate a method of treating appendicitis when the tip of the appendix is so bound down by infiltration and adhesions that the usual technic is impossible. He severs the base of the appendix, turns in and sutures over the stump, and draws the detached base to the skin and fastens it. He has applied this procedure in two cases; in one the vessels were injured, and the appendix became necrotic and could be lifted out the fourth day In the other case the appendix gradually shriveled and retracted, with no further disturbances.

Tuberculous Meningitis in Four Months Infant.—Muntendam describes the case of an infant succumbing to tuberculous meningitis at the age of 4 months. He ascribes it to birth injury from forceps delivery. The lumbar puncture fluid revealed no bacilli, but the symptoms and the fact that the child had lived for three weeks after birth in a room with a consumptive in the last stages of tuberculosis, rendered the diagnosis reasonable.

"Autostasis" and Medicine.—De Feyfer gives a historical sketch of the conceptions through the ages of the *vis medicatrix naturae*, the autostatic reaction processes, which produce the well rounded and harmonious life. The ancient Chinese symbol for it is the circle Tay-Ky, representing the positive, male and the negative, female forces of life. Health requires the balance complete between them. Disease is the encroachment of one on the other. The twentieth century has restored the ancient conception of the importance of the balance: the osmotic balance, the acid-base balance, loss of nervous balance, etc.

The Insulin Complement.—This is the term proposed by Lundsgaard and Holbøll for the active substance or principle in muscle tissue which—when finely divided muscle tissue is added to insulin in vitro and placed in contact with a solution of glucose—transforms alpha and beta glucose into the form which they call "new glucose." Neither alone can accomplish this transformation; it requires the combination of both muscle tissue and insulin.

Test Meals.—Kramer-Petersen expatiates on the advantages of a test meal (soup, egg, potato and bread) when the findings with the test breakfast do not explain the patient's complaints He gives the parallel findings in fifteen typical cases. The information thus derived is a guide to treatment with acids or alkalis; the test breakfast alone may not decide which is preferable.

ABNORMAL BACTERIA FLAGELLA IN CULTURES

THEIR RESEMBLANCE TO SPIROCHETES *

HIDEYO NOGUCHI, M.D.
NEW YORK

Since the introduction of dark ground illumination, which has become an indispensable means of studying certain spirochetes and filtrable micro-organisms, the possibilities for interpreting as spirochetes certain spiral elements encountered in examining culture materials have increased. Several papers dealing with the pseudoleptospira forms of citrated blood, which are seen especially after incubation at 37 C. for some time, have already appeared,[1] warning beginners not to mistake these for true leptospiras, but little attention has been given to still another source of misinterpretation not infrequently encountered in culture materials. In the present paper are recorded and discussed some observations such as once led me to mistake certain free bacterial flagella for involuted forms of a true spirochete.

In 1912, in an impure culture of *Treponema macrodentium*, a number of spiral elements were observed among typical forms of the spirochete. These elements were variable in width and length to an unusual degree. Some measured from 4 to 10 microns, and some from 20 to 40 microns. Each was provided with very regular, almost right angle windings throughout its entire length, the curves being wider at the median portion and gradually narrower toward the finely drawn ends. In large specimens the diameter of the spiral elements was several microns in the median portion and showed several parallel longitudinal striations along the axis as though in course of longitudinal division, while in minute specimens the filament measured only a fraction of a micron. The elements possessed no proper motility, appeared rigid and elastic, and showed slight affinity for Giemsa and other dyes. I thought these to be involuted forms of *Treponema macrodentium* under the conditions of impure cultivation (fig. 1).[2]

Several years later, in the course of attempts to cultivate the spirochetes of the gastric mucosa of dogs and cats and the spirochetal flora of stagnant water, it was repeatedly observed that when certain motile bacteria were present in the cultures, these free characteristic spiral elements were seen in varying numbers by dark field examination. Successive transplants of such cultures always carried both the spiral forms and the bacteria. While the bacteria might grow without the free spiral elements under certain conditions, no spiral elements appeared without the bacteria, and it looked at first as if the spiral elements were independent organisms growing in symbiosis with the bacteria. It was soon found, however, that these spiral elements could be made to appear from the bacteria at will by cultivating the latter on agar slants or semisolid "leptospira" medium. That the spiral elements are nothing but involuted flagella of the bacteria has been demonstrated by the fact that bacterial cells have sometimes been found with the flagella still attached at one or both ends, although as a rule the flagella of bacteria are invisible by dark-field illumination and are demonstrable only by special staining methods.

The size of these free bacterial flagella varies considerably in the same organisms and also with different varieties of bacteria, some bacteria giving rise to coarse spiral elements such as were observed in the impure cultures of spirochetes from the stomach of the dog (fig. 2 *A* and *B*), others to a form (fig. 2 *C, D, E*) not readily distinguishable from *Treponema pallidum*. Very delicate spiral filaments, which might readily have been confused with the minute spirochetes of the mouth, were recently found in a culture of *Leptospira icterohaemorrhagiae* which had become contaminated by bacteria through breaking of the culture tube during transportation (fig. 2 *G, H*). The spiral flagella are sharply drawn to invisibly fine points at both ends, and no buds or rudiments of the original attachment to the bacteria are recognizable; hence they appear as if they were leading an independent existence.

The possession of spiral terminal filaments, which develop to such abnormally large size under certain cultural conditions as to become visible, is common also in certain spirochetes, especially *Spironema* and *Treponema*. In their natural habitat the spirochetes of relapsing fevers or syphilis seldom show, under the dark field microscope, distinct terminal flagella, and when present they are seen only with the greatest difficulty owing to their extreme thinness. But in cultures these organisms invariably show a comparatively long and well defined, minutely curved spiral appendage at one end, sometimes at each end. These spirochetal flagella, however, are never seen to be compound in structure, as are some of the detached bacterial flagella, and they are seldom detached from the spirochetes (fig. 2 *I*).

In this connection a few words regarding the structure of *Spironema* and *Treponema* may not be amiss.

---

* From the Laboratories of the Rockefeller Institute for Medical Research.

[1] E. W. Schultz (J. Lab. & Clin. Med. **8**: 375 [March] 1923), in his discussion of artefacts in blood which simulate spirochetes, gives a considerable number of references on the subject.

[2] Dr. Theobald Smith, however, suggested at the time the possibility that they might be bacterial flagella.

The spirochetes of the various relapsing fevers (*S recurrentis, S. novyi, S. duttoni, S. gallinarum*) seem to consist of three main parts; namely, the cytoplasm, the spiral axial filament, and the flagellum. This structure can be readily demonstrated by allowing bile to act on the organisms. The cytoplasm is readily dissolved by the bile, and the thin axial filament, with regular spirals, is laid bare, the flagellum at either end remaining attached. The denuding process is easily followed by means of dark field illumination, and the results can be demonstrated by stained preparations. Figure 3 *A* shows the normal appearance of *S. recurrentis,* and figure 3 *B* the effect of the bile in exposing the thin spiral axial filaments. A normal specimen of *S. recurrentis* stained with Giemsa's solution after fixation with buffered solution of formaldehyde is shown in figure 3 *C*, while a corresponding preparation of a specimen treated with bile is shown in figure 3 *D*. Figure 3 *E, F,* shows similarly stained normal and bile treated specimens of *S. novyi.*

That the greater affinity for Giemsa's and other dyes shown by the relapsing fever spirochetes, as compared with *Treponema pallidum,* is due to the thicker cytoplasmic coat covering the axial skeleton is demonstrated by the fact that, after the removal of the cytoplasm the spironemes are more faintly stained than before bile treatment (fig. 3 *D, F*) and are reddish by Giemsa's method. The denuding process of bile takes place also in the case of *Treponema pallidum,* but with less striking results, owing to the thinness of the cytoplasmic coat.

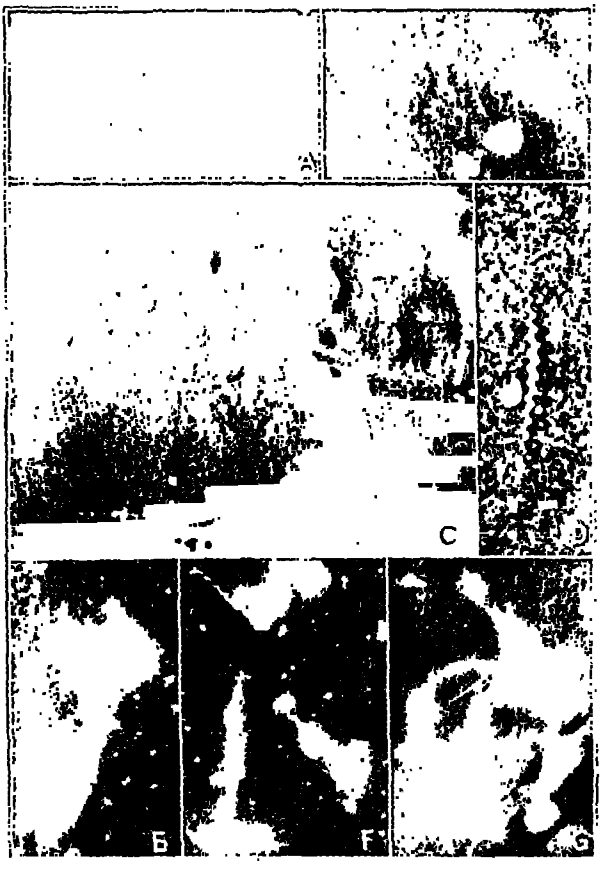

Fig. 1.—Spiral bacterial flagella encountered in an impure culture of Treponema macrodentium. All except *D* are dark field views magnified 1,000 times; *D* is a preparation made by Burri's india ink method, × 1,280.

Whether the flagellar substance of spirochetes is chemically identical with the axial filament is difficult to say, but both are spiral, are difficult to stain, are elastic in character, are similar in refraction of rays, and resist the lytic action of bile in certain concentrations. Unlike the treponemes and spironemes, the spirochetes of the *S. muris* group are normally provided with a large, distinct, readily recognizable terminal flagellum (fig. 2 *J, K*), and the cell body of these organisms is completely dissolved by bile, no trace of an axial filament remaining—perhaps none exists among this group, any more than among the true spirilla.

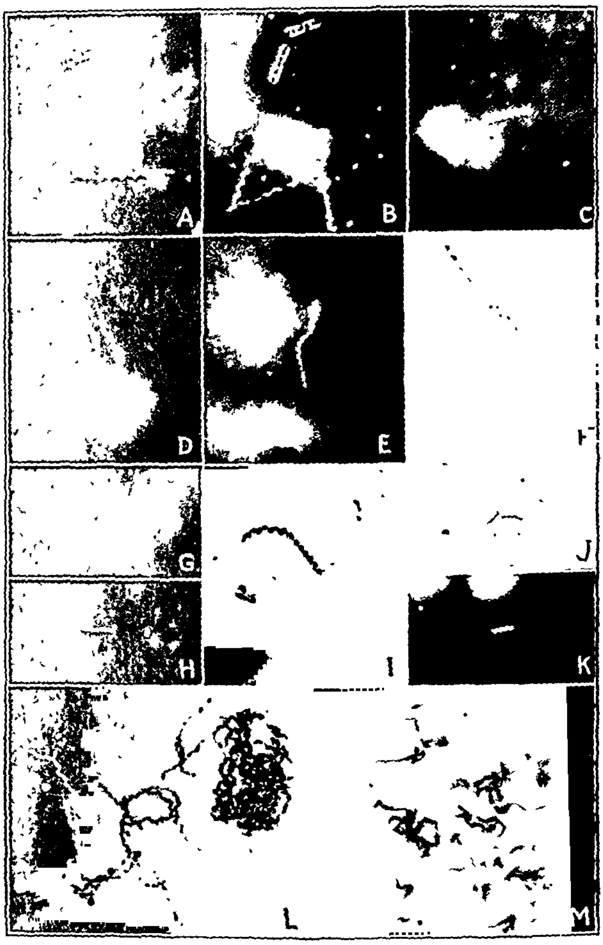

Fig. 2.—*A, B,* coarse spiral bacterial flagella in an impure culture of spirochetes from the dog's stomach; dark field views, × 1,000; *C, D, E,* *spiral elements* found in a culture of L. icterohaemorrhagiae from human blood; dark field views, × 1,000; *G, H,* spiral bacterial flagella in impure culture of L. icterohaemorrhagiae, × 1,000; *I,* dark field view of culture of Treponema pallidum, showing individuals with terminal flagella, and in lower left hand one detached flagellum; × 1,280; *J, K,* S. muris, showing terminal flagellum characteristic of this type of micro-organism; *J* is stained with Giemsa solution; *K,* a dark field view, both magnified 1,000 times; *L,* dark field view of pure culture of Treponema pallidum, for comparison; × 1,280; *M,* dark field view of pure culture of L. icteroides, for comparison; × 1,000.

Leptospira icteroides (fig. 2 *M*), *L. icterohaemorrhagiae,* and *L. hebdomadis* undergo granular disintegration when mixed with bile, and no axial filament comparable with that of the spironemes and treponemes has been demonstrated. No spiral elements (exaggerated free or attached flagella), such as those described for certain bacteria and spirochetes, have been encountered in the case of the leptospiras.

SUMMARY AND COMMENT

Besides the leptospira-like filaments, probably originating from red blood corpuscles under certain conditions in vitro, other spiral elements exist which may be erroneously interpreted as spirochetes. These are the exaggerated detached flagella of certain bacteria, produced under cultural conditions. In cultural studies of micro-organisms, the occurrence of these spiral elements must be borne in mind, particularly in connection with dark field illumination.

Spirochetes belonging to the *Spironema* and *Treponema* groups also produce, under certain cultural conditions, exaggerated flagellar appendages. These terminal flagella are similar in appearance and structure to the axial spiral filaments of the same organisms, but are much finer. The axial filaments are covered with a layer of cytoplasm which can be removed by the action of bile. The motility of these organisms resides in the portion of the filament next the attachment of the flagellum at either end.

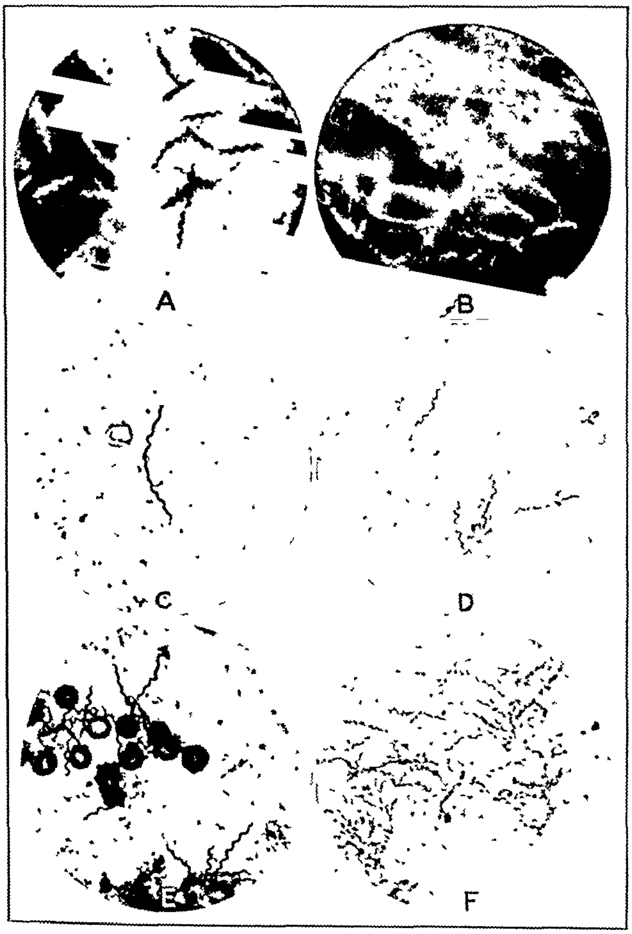

Fig. 3—*A*, dark field view of S recurrentis, × 1,000; *B*, the same, after it had been acted on by bile, *C*, S recurrentis fixed in buffered solution of formaldehyde and stained with Giemsa's solution, × 1,000, *D*, the same organism, after it had been acted on by bile, stained in the same way, *E*, S novyi, fixed in buffered solution of formaldehyde and stained with Giemsa's solution; × 1,000; *F*, the same organism, after it had been acted on by bile, stained in the same way

The great resemblance which exists between the flagella of motile bacteria and the flagellar and axial spiral apparatus of certain spirochetes seems to indicate that the axial filaments are probably a modified apparatus of similar origin especially adapted to the locomotion of spirochetes and therefore supports the hypothesis of a close phylogenic relationship between bacteria and spirochetes.

IDENTITY OF OHARA'S DISEASE AND TULAREMIA

EDWARD FRANCIS, M.D.
AND
DUNLOP MOORE, M.D.
Surgeons, United States Public Health Service
WASHINGTON, D. C.

The present account of what we have styled for convenience's sake Ohara's disease is based on two papers[1] published in Japanese, reprints of which were kindly sent to one of us by the author, Dr. Ohara of Fukushima, Japan. The first part of our paper presents the epidemiologic, clinical, bacteriologic pathologic and experimental observations made by Dr. Ohara. The second part presents our own observations, which were made at Washington, D. C., on material furnished at our request by Dr. Ohara and which have led us to the conclusion that Ohara's disease and tularemia[2] are identical.

CHARACTERISTICS OF OHARA'S DISEASE

Distribution.—Dr. Ohara's attention has recently been called to an acute febrile disease transmitted to man by the wild rabbits of the Abukuma Mountains in the eastern part of Fukushima Ken (prefecture), Japan. In January, 1924, a mother and two sons, simultaneously stricken with the same disease, sought treatment at Dr. Ohara's hospital. On careful investigation of the origin of the infection, he learned that symptoms had developed after they had all taken part in skinning or in dressing a wild rabbit which they subsequently ate. On making inquiry from various sources, Ohara ascertained that a disease of this nature had been prevalent among the villagers of the Abukuma Mountains for about twenty years. Dr. Ohara gives detailed histories of seven cases personally observed by him and reports of eight additional cases submitted by two physicians practicing in other parts of Fukushima Ken. Ohara's articles convey the impression that the infection is by no means uncommon in certain districts of the ken mentioned. Reference is made to cases occurring in five other kens but without, as a rule, details In general, the infected districts lie to the north and rather to the east of Tokyo.

Relation of Rabbit Epizootic to Human Disease.—At certain seasons, dead rabbits in great numbers are seen in the mountains, the infection seeming to rage severely among these animals during the hunting season; i. e., from late autumn to early spring. In Ohara's opinion, the disease in man is caused by contact with the uncooked meat of the infected rabbit. An etiologic relationship is shown between the act of touching the flesh with the fingers in skinning these wild rabbits or in dressing the meat, and the onset in man of a febrile disease with swelling of the lymph glands. Human infection occurs whether the wild rabbit has been found actually dead or whether he is captured while still alive but suffering from this disease. In Dr. Ohara's experience, those who merely eat the cooked flesh of the rabbit or touch only the external surface of the skin show no symptoms of illness. In his opinion, the danger lies only in contact of the fingers with the raw meat.

---

[1] Ohara, Hachiro: Concerning an Acute Febrile Disease Transmitted by Wild Rabbits A Preliminary Report, Jikken Iho, March 12, 1925, Japanese text, Human Inoculation Experiment with a Disease of Wild Rabbits, with a Bacteriologic Study, Kinsei Igaku **12**, no 5, Japanese text

[2] Francis, Edward: Tularemia, J A M A **84**: 1243 (April 25) 1925

Site of Infection and Lymph Glands.—Judging from the almost constant swelling of the lymph glands of the elbow and axilla, Ohara concludes that the site of infection must be the skin of the finger.

In two of Ohara's cases there were visible lesions of the fingers, in one instance containing a small quantity of pus, while in other cases macroscopic lesions of the fingers were lacking. It appears, therefore, that infection through the normal skin of the fingers is possible.

Enlargement of lymph glands (axillary, epitrochlear, etc.) is unilateral if only one hand is infected, but bilateral if both hands are infected.

Incubation.—The incubation period, as determined from case histories, may vary from one day to seven days.

Symptoms and Course.—After a short incubation the onset is sudden, with chilliness, or rigor and fever. Among other early symptoms are headache, languor, loss of appetite, vomiting, and articular and muscular pains. The important symptom, however, is inflammation of the lymph glands of the upper extremity, particularly those of the axilla and elbow. The adenitis may be unilateral or bilateral. The fever is at first continuous, later showing a morning remission, and may continue for several weeks; a temperature rise to 39 or 40 C. (102 to 104 F.) has been observed. In severe cases, the patient is confined to bed for several days. In a large percentage of cases, swelling of the axillary or other lymph glands goes on to suppuration. The axillary tumor may be tender or it may simulate a tuberculous adenitis, being practically painless and only slightly tender on pressure. The enlargement of the glands continues a long time, and they may still be palpable after three months.

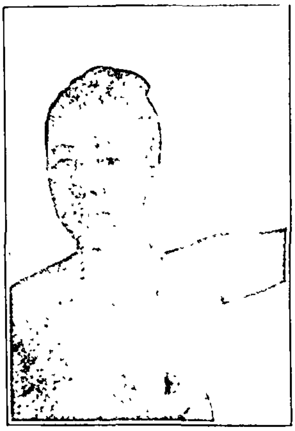

Fig. 1.—Axillary tumor prior to operation in experimental case.

Skin Eruption.—This is usually absent. In one case, a transient rash appeared on the face and neck.

Diagnosis.—This presents no difficulty, provided one is familiar with the symptomatology of the malady and its relationship to the disease of rabbits. In the presence of an epidemic, there may be confusion with typhus abdominalis.

Prognosis.—This is good; no fatalities directly due to the disease have as yet been reported.

Treatment.—Ohara employed neo-arsphenamine and surgery.

VOLUNTEER HUMAN INOCULATION

Mme. Ohara's cheerful offer of herself to help prove the scientific conviction of her husband adds one more to the long list of heroes of human experimental medicine.

A rabbit having been found dead in a district where numerous human cases of this disease had developed very recently, its heart was laid open under aseptic precautions and some of the contained blood and tissue fluids were lightly rubbed into the back of Mme. Ohara's left hand, Jan. 20, 1925, and about twenty minutes later the adherent material was washed off with soap. January 22, the patient complained of trifling tenderness of the left axillary gland on deep pressure, and slight headache. January 24, there was general malaise; rise of temperature (37.4 C.); enlargement of the left axillary gland to the size of a soy bean, and the patient was confined to bed. On the 25th, chilliness, articular pains, headache, languor, numbness of the extremities and constipation were noted. January 26, an axillary lymph node reached the size of the end of the index finger and was very tender, and both inguinal glands were swollen and were slightly tender. The temperature curve showed fever of nine days' duration (January 24 to February 1), which reached its maximum, January 26 (39.8 C., not charted). February 7, two axillary glands the size of a pigeon's egg and several smaller glands were removed at operation; the two larger glands had undergone suppuration. Two careful blood examinations were made, with the results shown in table 1.

Table 1.—*Blood Examinations*

	January 26	January 29
Number of erythrocytes	4,860,000	4,520,000
Hemoglobin (Sahli)	93%	90%
Number of leukocytes	12,500	18,000
Polymorphonuclear neutrophils	85.12%	72.34%
Eosinophilic leukocytes	0.15%	2.34%
Small lymphocytes	6.88%	16.35%
Large lymphocytes	4.31%	2.12%
Basophilic leukocytes	0.00%	0.31%
Large mononuclear and transitional cells	3.54%	6.54%
Arneth's count	Moderate shift to left	Slight shift to left

BACTERIOLOGY

Stained Smears.—Dr. Ohara demonstrated by stained preparations (1) in the pus of one patient's suppurating axillary glands an extremely small bacillus and a gram-positive diplococcus; (2) in the pus from another patient's finger, a pseudodiphtheria bacillus and a gram-positive diplococcus, and in pus from the elbow gland of the same patient, the same diplococcus in large numbers; (3) in another patient, pus from the center of an excised axillary gland showed a few gram-positive diplococci.

Cultures.—Stab cultures made on blood agar of pus from an excised axillary gland of the experimental human case yielded a bacillus resembling morphologically the tubercle bacillus and two kinds of diplococci. Smears of the heart blood of the rabbit used in the human transmission experiment showed similar diplococci.

Causative Organism.—Dr. Ohara does not claim to have isolated the causative organism of the disease in pure culture.

PATHOLOGY

Histologic examination of the lymph gland excised in the human experimental case showed round cell infiltration, dilatation of the blood vessels, extravasation of blood, small pus cavities, caseation and giant cells.

ANIMAL INOCULATIONS

Dr. Ohara performed no animal transmission experiments. The necropsy report of the rabbit found dead and used for his human transmission experiment does not contain specific mention of the typical lesions of tularemia in the spleen, liver and lymph glands. There is one reference[3] to yellow specks having been seen on section of the livers of dead rabbits.

REPORTS OF TWO CASES OF OHARA'S DISEASE[4]

CASE 2.—M. S., a woman, aged 46, a farmer, caught a live rabbit, Dec. 28, 1923, which was dressed by her eldest son (patient 3). Taking up the meat with her left hand, she placed it in the pot. At this time there were no visible lesions on the fingers of the left hand. On the third day (December 30) there suddenly appeared chilliness, a marked feeling of general malaise, and loss of appetite. On the fifth day, the patient became aware of a considerable swelling, tender on pressure, in the left axilla. After employing various kinds of symptomatic treatment for about ten days, she finally became able to walk, and on Jan. 7, 1924, sought treatment at the dermatologic department of Dr. Ohara's hospital.

The patient was well developed physically and well nourished. The fingers of the left hand showed no abnormalities or evidence of injury; the lymph glands of the left axilla and left elbow were greatly swollen; the temperature, 38.2 C. The diagnosis was acute adenitis of unknown origin. Local applications were prescribed, and the patient was directed to return home.

January 15, the patient returned to the hospital; the temperature was 38 C.; a general feeling of malaise was still present. Tentatively an intravenous injection of neo-arsphenamine was administered. On the following day the constitutional symptoms suddenly disappeared and the appetite showed improvement.

January 21, the temperature was 36.8 C. After the first injection subjective symptoms were entirely absent and the patient progressed favorably, yet on account of the persistence of swelling of the lymph glands a second injection was given.

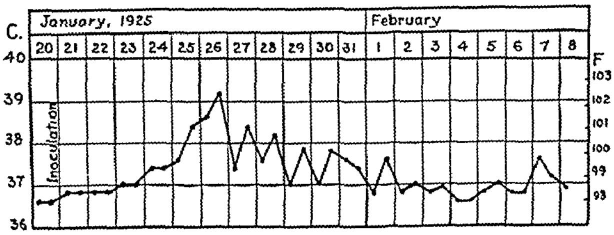

Fig 2.—Temperature in experimental case

January 26, a third injection of neo-arsphenamine was given. January 30, the lymph nodes having greatly diminished in size and no longer exhibiting tenderness on pressure, treatment was suspended. The course of the disease was thirty-three days.

CASE 3.—T. S., a man, aged 25, eldest son of patient 2, with the aid of his younger brother, Dec. 28, 1923, cleaned a wild rabbit that was alive when captured. In dressing the animal, he held the knife in his right hand and grasped the flesh with his left hand. He states that at that time he observed no lesions whatever on either hand. On the third day, December 30, just as in the case of his mother, chilliness and a febrile attack supervened. By evening, being much indisposed, he took to bed. A feeling of chilliness came on daily. The patient stated that on the fifth day he observed a large tumor in the left axilla.

Jan. 15, 1924, he came to Dr. Ohara's hospital, accompanied by his mother. He was well developed and well nourished. There were no lesions on the fingers of either hand. The left epitrochlear lymph node was swollen to the size of the end of a thumb; the left axillary glands were enlarged to the size of a small apple, and, while not painful, exhibited tenderness on pressure; the temperature was 38.2 C. The thoracic and abdominal viscera were apparently normal; the color of the skin was normal; there was no albumin or sugar in the urine; the Wassermann reaction was negative. An injection of neo-arsphenamine was given.

January 24, the temperature was 37.5 C. Following the first injection, the feeling of general malaise disappeared and the patient became able to resume work. The swelling of the glands at the elbow was somewhat diminished; there was no change in the condition of the axillary glands. A second injection of neo-arsphenamine was administered, after which the patient felt as though he was entirely cured and was so regarded. February 24, he again visited the hospital on account of a slight softening of the axillary glands, which now showed fluctuation on palpation. On incision, yellow, odorless pus was evacuated. A number of smears of the pus were prepared and stained with Loeffler's solution. On examination an extremely small bacillus, resembling the tubercle bacillus, and a gram-positive diplococcus were demonstrated.

TESTS MADE AT WASHINGTON, D. C.

Agglutination.—At our request, Dr. Ohara furnished us with blood serums from seven cases which came under his observation. Serums 1, 2 and 3 were received at the Hygienic Laboratory, United States Public Health Service, Washington, D. C., Oct. 27, 1925; serums 6, 7 and 8, November 25; serum 9, Jan. 5, 1926. These were tested for agglutination of *Bacterium tularense* together with proper positive and negative control serums, with the results given in table 2.

Analysis of the table shows that the serums of long-recovered cases 1, 2 and 3 agglutinated *Bacterium tularense* promptly and completely in dilutions of 1:10 and 1:20, and that the serums of cases 6, 7, 8 and 9, taken in the third, fourth and fifth weeks of illness, at the height of agglutinin production, agglutinated *Bacterium tularense* promptly and completely in dilutions of 1 to 10, 20, 40, 80, 160 and 320, but not in higher dilutions. These results are in accord with those obtained when testing tularemia serums collected from long-recovered cases and from acute cases.

Isolation of Culture.—Jan. 5, 1926, we received from Dr. Ohara a portion of a human lymph gland which he had removed from a patient, Nov. 30, 1925. We injected the gland tissue into guinea-pigs, which died acutely manifesting the typical lesions of tularemia—spotted spleen and liver and caseous lymph glands; from these animals we isolated a culture on coagulated egg yolk and glucose cystine agar. This culture was compared with *Bacterium tularense*, with which it was

[3] Idogawa, cited by Ohara.

[4] Ohara (footnote 1, first reference).

found to agree in its morphologic, biochemical and cultural characteristics

Animal Inoculations—Guinea-pigs, rabbits and white mice were inoculated with the culture, and they died acutely manifesting the typical lesions of tularemia, in these animals the infection has now been propagated by animal transfers for a period of two months

Pathology—Microscopic sections of the spleens, livers and lymph glands of the experimental animals show the typical histopathology of tularemia

Agglutinin Absorption—Antiserums were prepared by immunizing one rabbit against Ohara's strain and another rabbit against an American strain The two rabbit serums were then compared by methods of reciprocal agglutinin absorption and resulted in proof of the agglutinogenic likeness of the Japanese and American cultures

SUMMARY AND CONCLUSION

Dr Hachiro Ohara's description of the clinical and epidemiologic characteristics of a disease which he has observed in Fukushima City Japan agrees even in minor details with the picture of tularemia

The following tests were made in Washington D C, by the United States Public Health Service 1 Serums collected and forwarded by Dr Ohara from cases which came under his observation agglutinated *Bacterium tularense* 2 Glandular tissue removed from a human case and forwarded by Dr Ohara caused tularemia in laboratory animals from which *Bacterium tularense* was isolated 3 Reciprocal agglutinin absorption tests failed to distinguish any difference between the Japanese culture and an American culture

The conclusion is reached that Ohara's disease occurring in Japan and tularemia occurring in the United States are identical

---

ANGIONEUROTIC EDEMA

REPORT OF CASE, WITH NECROPSY FINDINGS *

ISABEL M WASON, MD
NEW HAVEN, CONN

In 1882, Quincke described a condition characterized by a sudden appearance of localized and circumscribed edema in various regions of the body He named this condition "acute circumscribed edema" It is usually transient and is not associated with untoward consequences unless the larynx is involved, in which case the person affected may die Since the publication of the paper referred to, a number of writers have described the condition under various names, for example, Quincke's disease, Quincke's edema, angioneurotic edema, hereditary edema, familial edema, and giant urticaria

It has been impossible up to the present time to establish a definite etiologic basis for this disease Apparently, it occurs with equal frequency in the sexes during any period of life, and the lesions have been observed in practically every region of the external surface of the body and in the thoracic and abdominal viscera The duration of an attack varies from a few hours to six days It has been suggested that the condition is a manifestation of protein sensitiveness but evidence is lacking to support the idea An interesting fact established, however, has to do with the apparent hereditary nature of the condition This aspect of the subject has been dealt with by Osler,[1] Ensor, the Crowders[2] and Bullock[3]

The literature describing this disease has been reviewed by Fairbanks,[4] the Crowders[2] and others. In spite of a large number of reports of instances of the disease, many of which terminated fatally, there are few records of postmortem findings It may be said, however, that reports by Harbitz,[5] Griffith[6] and Morris[7] contain good descriptions of the associated pathologic anatomy In this communication I report an instance of the disease involving the larynx—death resulting—together with the necropsy findings

REPORT OF CASE

History—I W, a baby girl, aged 14 months, was brought to the New Haven Hospital, where it was pronounced dead. The facts related by the mother are as follows

The child awoke and was given a cup of milk, a few minutes later it began to cry, and in a short time it appeared to be choking The tongue was observed to protrude and to have become blue, and the neck became big and hard The child was rushed to the hospital but died on the way The admitting physician reported that the body was well developed and well nourished No swelling was noted about the face The skin was clear except for patches of eczema on the face There was generalized enlargement of the superficial lymph nodes The tonsils were moderately enlarged On palpation, the pharynx and epiglottis were found to be so thick and boggy that the entrance to the larynx was completely obstructed

It was learned from the mother that, during the month just past, on several occasions the child had had swellings appear on various parts of the body, but they had disappeared in each instance in a few hours In particular, the hands and feet, the eyes, and lower lip became twice their natural size No constitutional symptoms were noted, however As far as the mother could tell, the child appeared perfectly well the night before the attack already described, which resulted in death No history could be obtained of any important illness previous to this

The following considerations about the family history are interesting There were five children, three boys and two girls One daughter died under circumstances similar to those described in the case under consideration A boy, aged 8, had an attack in which swelling began about the eyes and then spread until the nose and throat were involved Swallowing was difficult and painful The boy was taken to the hospital, where it was further observed that the tonsils were enlarged and the uvula and posterior pharynx were swollen and edematous There was no enlargement of the superficial lymph nodes Ten minims (0 6 cc) of epinephrin were administered and the edema decreased within twenty minutes, but did not disappear until twelve hours later Subsequently, tests were made with a variety of proteins for sensitiveness A marked reaction was obtained with cat's hair and beef, however, no outstanding disturbance was observed to follow the child's eating beef or playing with a cat

The other two boys had not shown any symptoms

Necropsy Report—Postmortem examination was made six hours after death Save for some swelling of the left thumb and marked cyanosis of the lips, there were no remarkable external manifestations

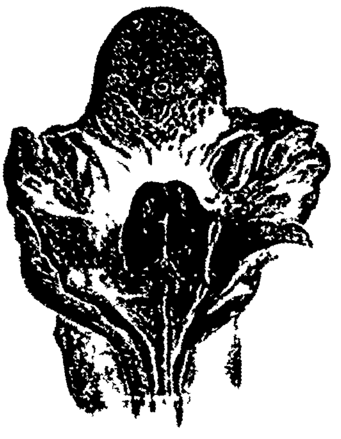
The changes of particular interest were confined to the respiratory system. The wall of the lower posterior and lateral pharynx and the uvula were markedly swollen, pale, and translucent in appearance; the tonsils and tongue were not edematous. There was an extreme edema of the epiglottis, aryepiglottic folds, and the cuneiform and corniculate tubercles, so that their outlines were obliterated, as shown in the accompanying illustration. Only two large, swollen, translucent vertical lips were seen, which completely approximated each other except for a tiny diamond-shaped orifice not more than 1 mm. in its greatest transverse diameter. Each lip measured 2 cm. from its origin on the posterior larynx—at the obliterated interarytenoid notch—to its tip. The tip almost reached the swollen uvula. The trachea and larynx were opened anteriorly so as to obtain a good view of the larynx from below. The swelling extended downward and involved the vocal cords to a moderate extent, but there was no evidence of edema below the cords. The lungs were voluminous and purple. They had a somewhat doughy, homogeneous consistency, and pressure on either lung caused pink, frothy fluid to exude into the trachea. Occasional pinpoint hemorrhages were seen over the pleural surface. Section was made after fixation of the whole specimen. The cut surface appeared homogeneous, and pink fluid exuded from the alveoli and bronchioles.



Edema of the epiglottis and larynx, with almost complete closure of the orifice

Microscopic examination of the lungs showed edema which involved the alveoli moderately, and the subpleural, peribronchial and interlobular connective tissue markedly. It was shown in some areas by a pink staining, granular material, and in others only by a spreading apart of the tissue. The alveolar walls were congested, and in some of the alveoli a few red blood cells were seen. The bronchioles contained a few desquamated epithelial cells, red blood cells and a little serum. The peribronchial lymphatic tissue was slightly increased. In the wide interstitial bands the blood vessels seemed large, but there were also very conspicuous lymphatics, some with intact and others with ruptured walls. Small hemorrhages or scattered erythrocytes were seen here and there, and not infrequently polymorphonuclear cells, many of them with an eosinophilic granular cytoplasm, were seen in small accumulations or were scattered more diffusely through a wider zone.

In the pharynx, adjacent to the larynx, the picture was also mainly one of edema, which lifted up the mucosa, spread apart glands, muscle bundles and even muscle cells, and extended into the deeper submuscular connective tissues. The blood vessels and lymphatics were moderately dilated. The cells here were chiefly of the small mononuclear type, although a few polymorphonuclears and large mononuclears mingled with them. They were most conspicuous in the submucosa but invaded the lower layer of the mucosa and the intramuscular bands.

The lymphoid tissue everywhere was abundant and hyperplastic. The large pale centers of the malpighian corpuscles in the spleen and of the lymph follicles in the intestines and in the nodes showed numerous mitotic figures.

COMMENT

The condition described above is that of an extreme edema of the respiratory tract, with a mild and variable type of cellular reaction. In some sections of the lungs, the character of the response suggests an early inflammation. In other sections of the lungs and the pharynx the picture is not unlike that sometimes seen following protein sensitization; namely, a predominance of mononuclear cells.

URINARY PROTEINS

CRYSTALLINE PROTEINS OF NEPHRITIS *

WILLIAM H. WELKER, Ph.D.
WILLIAM A. THOMAS, M.D.
AND
LUDVIG HEKTOEN, M.D.
CHICAGO

Crystalline proteins have been isolated from the urine up to the present time in only eight cases.[1] In the course of work on human blood proteins, difficulty was experienced in obtaining blood for the preparation of sufficient quantities of albumin. This led to an attempt to separate this protein from the urine of patients with nephritis that were eliminating large quantities of protein. In the course of this work it was discovered that, under certain conditions, proteins in the cases studied tended to become crystalline.

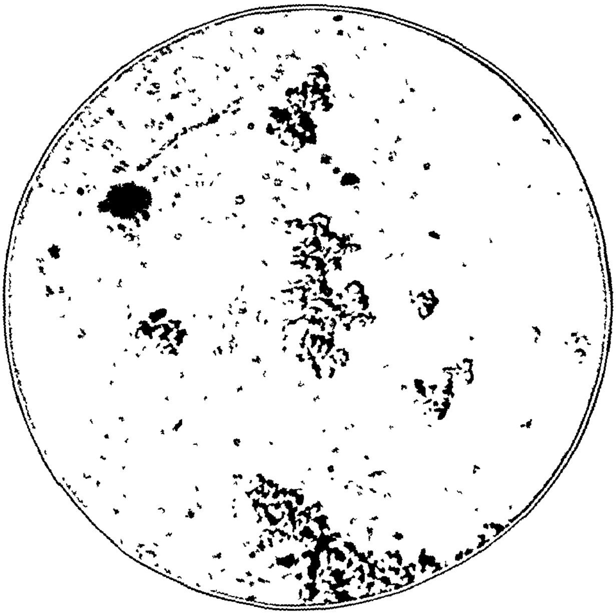


Fig 1.—Typical globular protein crystals obtained from urine of patients with nephritis

As a preliminary treatment, the urine was saturated to 25 per cent with ammonium sulphate, left standing

for a few minutes until flocculation had taken place, and then filtered. The filtrate was placed back on the filter paper until a clear fluid was obtained, which was completely saturated with ammonium sulphate. The precipitate was dissolved with the requisite amount of distilled water giving a protein solution of moderate concentration. This solution was treated with saturated ammonium sulphate solution until a slight, but permanent, flocculent precipitate formed. The mixture was then filtered and refiltered until a crystal clear fluid resulted. The solution was set aside in a crystallizing dish, and usually at the end of twenty-four hours a copious sediment had appeared, which under the microscope was composed of globular crystals of protein, as shown by appropriate tests. After standing for a number of days, but before any gross separation of ammonium sulphate had occurred, the solution was filtered, the sediment on the filter paper dissolved in distilled water and again treated with saturated ammonium sulphate until a slight but permanent precipitate had formed. The solution was filtered and refiltered until clear, and again set aside for crystallization. Again globular crystals of protein appeared at the end of twenty-four hours.

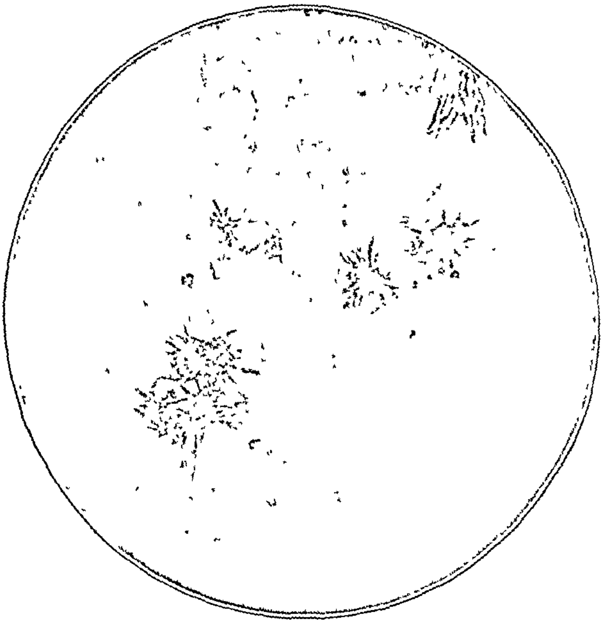

Fig 2.—Needle shaped protein crystals obtained in second crystallization of proteins obtained from the urine in one of the cases studied

So far, we have studied the urine in ten cases of nephritis, and in all, the globular crystals of protein (fig. 1) have been obtained. In one case the second crystallization yielded definite needle-shaped crystals, as shown in figure 2. Of the ten cases, three were instances of marked hypertension, with no edema; three, of hypertension, with edema, but no decompensation; two, of hypertension with decompensation; one, an acute glomerular nephritis in a child, and one, a marked generalized anasarca of undetermined origin. Of the ten patients, five have died, two in the pure hypertension group, one of hypertension with edema, one in the decompensated group, and the anasarca patient. Necropsies of the two patients with pure hypertension and with decompensated hypertension revealed no changes other than the renal, vascular and cardiac changes common in such conditions.

The proteins obtained on the second crystallization have been tested with specific precipitin serums for human albumin, euglobulin and pseudoglobulin, and all three of these proteins were present in considerable quantities in the crystalline preparations from all the urines studied.

SUMMARY

In ten cases of nephritis, proteins were obtained in the form of globular crystals from the urine. In one instance, the protein appeared as needle-like crystals. Precipitin tests indicate that the protein crystals consist of compounds of serum albumin, euglobulin and pseudoglobulin.

IODIZED SALT IN THE PREVENTION OF GOITER

IS IT A SAFE MEASURE FOR GENERAL USE? *

C. L. HARTSOCK, M.D.
CLEVELAND

During the last year, we have been impressed by a great increase in the incidence of hyperthyroidism and particularly by the appearance of an unusual type of thyroid hyperactivity in men. We have therefore made a special study of these cases with particular reference to the possible etiologic factors involved, and have found that the accumulated evidence seems to point conclusively to the continued ingestion of small amounts of iodine in the insidious form of iodized salt as the primary exciting factor. For this reason, we feel that it is important to call the attention of physicians, and through them of the public, to the misunderstanding that has gradually arisen regarding the use of iodine in endemic goiter, particularly in the form of iodized salt. Without any precaution being given for its use, this salt is being vigorously promoted by the combined propaganda of health officials and of salt companies, who, through the agency of newspaper articles, civic meetings and attractive advertising, have gradually created the impression in the lay mind that iodine is a panacea for all goiter conditions and will ultimately solve the whole endemic goiter problem. For example, the issue of *Hygeia* for February, 1926, contains an advertisement of iodized salt, which includes the following quotations under the caption "What Well-Known Medical Men Say":

> "Iodine is almost an absolute preventive of goiter. That has been proved beyond all question. Given in table salt it is a preventive for goiter."—Dr. Charles H. Mayo, in an address before the Wayne County Medical Association, Jan. 26, 1924.
>
> "Iodine is not a medicine. It is simply a replacement of one of the needed elements in food. We urgently ask the people of our city to use iodized salt both for table and cooking."—Dr. C. S. Slemmons, City Health Commissioner, Grand Rapids, Mich.

As a result of such propaganda, during the last year the general use of iodized salt has become very extensive in the Great Lakes and West Virginia goiter regions.

The question as to whether hyperthyroidism is induced by the administration of iodine has been recently discussed by O. P. Kimball,[1] who, by means of a statistical study of cases from the Cleveland Clinic, showed that a large number of the patients had used iodine in some form. His report proved rather conclusively that iodine would activate the thyroid gland to hypersecretion, but he felt at that time that the small amount of iodine contained in iodized salt could hardly be responsible for the production of hyperthyroidism except in cases of long standing adenoma. Since the writing of that article, however, its dangers are becoming more apparent, for iodized salt is now being very much more extensively used by the public than other forms of iodine, such as sodium iodide, iodostarine and compound solution of iodine (Lugol's solution), probably because of the propaganda to insure its use and also because of the fact that when one member of a family is advised to use iodized salt the whole family must use it, as its use in cooking is always advised. This extensive use of iodized salt appears to be a plausible explanation of the fact that between 25 and 50 per cent of all the cases of hyperthyroidism in which operation has been done here during the last six months appeared to have been directly due to or exacerbated by this agent. The wide range of these figures is due in part to the fact that some of the patients had had symptoms of the disease before using the salt, so that we must take into account the possibility that in some of these cases, even though the earlier symptoms were mild, "full-blown" hyperthyroidism might have developed without the use of iodized salt, and in part to the fact that it is impossible in some cases to establish the exact

Analysis of an Unusual Type of Hyperthyroidism in Sixteen Men

Age and Occupation	Duration of Symptoms, Mo.	Duration of Use of Iodized Salt, Mo.	Loss of Weight, Pounds	Weakness	Nervousness	Tremor	Pulse Rate	Blood Pressure	Presence of Goiter Before Taking Salt	Condition of Thyroid on Examination	Exophthalmos	Basal Metabolism Rate	Infection	Pathologic Condition	End-Result
42 Office work	12	18	25	++	++	++	104	166/70	Slight	Soft vascular, bruit	Slight	+50	Teeth questionable	Colloid goiter	No improvement after operation; when 3 months later similar cases called attention to use of iodized salt and he stopped its use, improvement resulted
41 Electrical engineer	6	12	45	++++	++	++	150	110/70	None	Small, scarcely palpable, firm	Slight, staring	+49	Abscessed teeth	Hyperplasia	Use of iodized salt not discovered until after operation; marked improvement on discontinuance
39 Real estate dealer	6	12	6	++	++	++	130	130/70	Not noticed	Very slight edema of right lobe	Slight, staring	+50	Abscessed teeth	Not operated on	Slight improvement after two months rest
35 Office work	2	6	12	++	++	++	104	144/70	None	Soft, small struma, not visible	Slight, staring	+29	Teeth questionable; not roentgenographed	Refused operation	No improvement after three months rest
43 Office work	8	12	56	++++	++	+	132	168/58	None	Moderate diffuse enlargement with bruit and thrill	Slight exophthalmos	Not taken	Chronic tonsillitis	Operation advised	Did not return for operation
32 Clerk	12	24	30	+	+	+	110	130/70	Not noticed	Normal	Slight, staring	+26	Two teeth recently extracted	Not yet operated on	
34 Clerk	3	12	40	++	+	+	120	120/80	Not noticed	Firm, moderate size bilateral enlargement	None	+47	Marked oral sepsis	Colloid goiter	Excellent condition
39 Inventor	6	18 24	30	++++	++	+	140	110/65	Not noticed	Scarcely palpable	None	+34	Abscessed, infected tooth, tonsils	Colloid goiter	Excellent condition; gain of 15 pounds in 3 weeks
35 Manager of store	9	12	20	++	+	++	120	130/60	Not noticed	Fairly soft, slightly enlarged	Slight	+56	Questionable teeth	Fetal adenoma, colloid goiter	Improvement; gain of 15 pounds; marked tremor still present; continued use of iodized salt just discovered
51 Grocer	5	8	15	++++	+	+	118	144/66	Not noticed	Scarcely palpable	Very slight	+71	Questionable teeth	Refused operation	Slight improvement in 6 weeks under medical treatment
55 Merchant	7	16	40	++++	+	+	128	146/62	Not noticed	Scarcely palpable	Slight, staring	+41	Oral sepsis	Ligated only	Improvement
32 Office work	1	8	8	+	+++	+++	92	140/80	None	Very small, firm, struma	None	Not taken	Suspicious teeth	Colloid goiter	Marked improvement
45 Office work	6	12	22	+	+	+	110	115/60	Slight goiter	Soft, nodular moderate size	None	+68	Abscessed teeth, removed recently	Fetal adenoma with colloid goiter	Marked improvement
37 Road building	5	24	37	+	+	+	120	145/70	None noticed	Small nodular goiter	None	Not taken	Chronic tonsillitis	Slight hyperplasia	Marked improvement
43 Postman	2 wk.	5 wk.	15	++++	+	++	106	140/70	Large goiter congenital	Large, soft, vascular goiter recently grown smaller	None	Not taken	Abscessed teeth	Not operated on	Condition worse
43 Biochemist	1	3	8	+++	++	+	104	114/50	Goiter for number of years	Soft vascular goiter	None	Not taken	Abscessed teeth	Not operated on	Operation advised; after two months rest no improvement

time relation between the onset of the symptoms and the initial use of the salt. But even when these facts are taken into consideration, the relation between the use of iodized salt and the disease is so definite in the minimum number of cases, 25 per cent, as to leave little doubt as to its rôle.

REVIEW OF CASES

Because of the difficulties in collecting exact statistical information regarding these cases of hyperthyroidism *en masse,* it seems more conclusive to offer, as proof of the dangers of this salt, data from the group of cases in men, which first called our attention to this problem. Since individual case reports consume much space and include details not pertinent to our subject, the essential points in the history and examination of each patient have been grouped in the accompanying table. These patients were all in excellent health before the onset of toxic symptoms, and in only two cases was the iodine used because of a supposed need of the patient himself, the other patients being "innocent victims" of the general use of the salt in the family cooking.

A study of these cases revealed the following interesting features:

(*a*) With the exception of the postman, all the patients were engaged in mental work, and even in his case a sudden increase in the number of new names which he had to memorize was causing him a great deal of worry.

(*b*) There was a striking uniformity in age.

(*c*) The onset of symptoms was invariably associated with the use of iodized salt, being first noted from one to eighteen months after the use of the salt was begun.

(*d*) In most of the cases the first symptom noticed was loss of weight or marked weakness, particularly of the legs; the nervous and cardiac symptoms appeared later, the symptoms usually appearing in a reverse order in the noninduced form of hyperthyroidism.

(*e*) Exophthalmos was almost invariably absent, the ocular signs being limited to a staring expression.

(*f*) The thyroid differed markedly from the usual type, as it was almost invariably a small, firm and scarcely palpable gland rather than the usual palpable, vascular gland with thrill and bruit; in two of the exceptional cases, iodized salt had been used for the cure of the goiter.

(*g*) The pathologic report in these cases, usually "colloid goiter" or "very mild hyperplasia," was also strikingly different from that usually given in cases of hyperthyroidism; this circumstance is in accord with the conclusions of Reinhoff,[2] which will be mentioned later.

(*h*) The presence of foci of infection was demonstrated or suspected in every case, and it would be interesting to try to trace their influence in the production of the hypersensitive condition which can be so affected by iodized salt.

(*i*) The high incidence of this disease in men during the last six months, as compared with the very low incidence which our previous experience had led us to expect, has been very striking; the most plausible explanation that we can offer is the fact that men as a rule use a great deal of salt.

While these are cases of frank hyperthyroidism, presenting all the features of exophthalmic goiter, it is evident that they differ strikingly in many ways from the average male case of hyperthyroidism. Previous to the past year, such cases have rarely been seen in the Cleveland Clinic, although, on an average, 1,500 cases of hyperthyroidism are seen here annually. When, therefore, sixteen of these patients presented themselves within six months, every one of whom had used iodized salt, while during this time no cases of acute hyperthyroidism in men were seen who had not used the salt, the evidence seemed conclusive that iodine in this form would arouse even a normal thyroid gland to hyperactive secretion. In fact, after the riddle of the causation of this condition was solved, it was easy to astonish such a patient, when he had made a brief statement of his complaint, with the query: "How long have you been using iodized salt?"

In addition to these cases in which there seems to be no question that hyperthyroidism was induced, I wish to mention briefly other groups of cases which, although the symptoms and signs do not differ from the usual picture of this disease, seem to belong also in this category. We have been convinced that this is the case, not only by the great increase in the incidence of hyperthyroidism since the use of iodized salt has been in vogue, but also because in each instance the onset of the symptoms has followed shortly after the initial use of the salt.

Among these groups, that in which the evidence was perhaps most conclusive was composed of eighteen women between the ages of 45 and 65. Their histories were identical in almost every respect. In every instance the patient had had a large neck or a lump in the neck throughout adult life but had never had any trouble until a friend, the grocer, or an article or advertisement in a newspaper had persuaded her that iodized salt was good for goiter, and she had begun to use it in cooking. At intervals varying from two to twelve months, these patients had become very weak, had lost weight, had grown nervous and short of breath, and had developed palpitation and, in many cases, irregularity of the heart. Some of the patients had no conception between these symptoms and their goiters, and were jubilant over the fact that the latter had decreased in size with the use of the salt. Examination revealed a fetal or large colloid adenoma in every case, with the usual signs of hyperthyroidism, particularly degeneration of the heart muscle with decompensation. Auricular fibrillation was present in twelve of the eighteen cases. The basal metabolic rate was taken in nine of these cases and was found to range from plus 25 to plus 90. Thirty-two other patients might be included in this group of middle aged women with adenomas, but they had had symptoms before using the salt; in fact, each of them had used it because she had been told that her trouble was due to her goiter, and each hoped to be cured by using the iodized salt. The resulting exacerbation of the symptoms was so severe that an operation was necessary in each of these cases. Moreover, the cardiac decompensation was so marked in many of the cases that the operative risk was greatly increased. The medical profession has always considered that this type of goiter is extremely susceptible to the effects of iodine, and therefore has exercised great care in its administration; but unfortunately this precaution has been overlooked in the enthusiasm over the new "cure."

Another type of patient has also appeared at the Cleveland Clinic more frequently than usual during the last six months, a type of case in which it has always been thought that iodine could be administered almost ad libitum—young girls at the age of puberty, either with or without a struma. Five cases of outspoken and extremely severe hyperthyroidism in girls from 12 to 18 years of age have been seen during this period, and in all these cases the hyperthyroidism developed after the use of iodized salt was begun. Small fetal adenomas were present in two cases and moderately large, uniformly shaped goiters with a slightly increased vascularity in the other three. Besides these outspoken cases there have been a large number of patients in this age group who, having small goiters, have used iodized salt and have subsequently developed very mild nervous symptoms, and have noticed a decrease in their powers of endurance and in their efficiency. Although these cases are classified as adolescent colloid goiters, they seem to show a mild degree of toxicity.

---

[2] Reinhoff, W. F.: Bull. Johns Hopkins Hosp. **37**: 285-305 (Nov.) 1925.

The recurrence of hyperthyroidism in three patients who had enjoyed good health from four to thirteen years after thyroidectomy was also attributed to the use of iodized salt. It should be noted that after an operation for hyperthyroidism patients are highly sensitized to iodine, and therefore special precaution should be exercised against its use in postoperative cases.

Very few cases of outspoken hyperthyroidism were seen in patients between the ages of 20 and 35, but there were many who, after using the salt, had suffered from nervous symptoms such as insomnia, irritability, depression, lack of concentration, emotional disturbances, sweating, flushing, palpitation of the heart, paroxysmal tachycardia, and had noticed a loss of weight and lack of endurance which could not be explained except as the effect of the iodine. This explanation seems the more plausible because some of these symptoms were the earliest ones in the cases in which a frank hyperthyroidism developed.

It may not be amiss to mention here two facts which have been noted in our dermatologic department within the last six months; first, that iodine rashes have been appearing frequently, and, second, that cases of acne vulgaris become much worse or will not respond to treatment while iodine is being used in the form of salt.

HISTORY OF GOITER TREATMENT

These many instances of unfavorable results following the use of iodized salt make us feel that it is surprising that any one would advocate its use. However, it is only natural that it should be advocated and advised when one traces the relation of iodine to goiter and sees how every step in the development of the latter seems to prove that small amounts of iodine administered in a natural way will solve the problem of endemic goiter. The early Greeks were the first to use iodine in the treatment of goiter. They used for this purpose the ashes of burnt sea sponges, which contain a large amount of iodine, but they did this without knowing the active element. It was not until 1820 that Coindet reported that goiter could be reduced in size by the use of iodine. In 1856, Chatin observed that goiter was very prevalent in localities in which the iodine content of the soil and water was low—probably because the solvent action of melting glaciers carries the iodine to the sea—and suggested that it could be prevented by supplying this deficiency. In 1896, Bauman discovered that iodine is stored in the thyroid gland in large quantities. In spite of these discoveries, however, very little was known regarding the action of iodine on the thyroid gland until 1907, when Marine[3] and his co-workers began their classic studies of the effect of iodine on the structure of the thyroid gland. They concluded that all thyroid hyperplasia was essentially the same and due to a lack of certain nutritional elements in the food, and that a resting state could be induced by the administration of iodine. As a result of this experimental work in animals, Kimball,[4] under the direction of Marine, began the systematic study of the prevention of simple goiter in man, by giving iodine in small amounts to several thousand school children in Akron, Ohio, from which he derived the following conclusions:

1. Simple goiter can be prevented by the administration of small amounts of iodine.
2. One third of the cases of uncomplicated simple goiter disappear or are markedly decreased by the internal administration of a small amount of iodine.
3. The administration of small amounts of iodine does not produce a toxic condition (exophthalmic goiter).
4. The administration of 2 Gm. of sodium iodide, twice yearly, is practical and economical and can be recommended as a public health measure in goiter districts.

This investigation led to great activity on the part of public health officials, and many methods were suggested for the efficient and economical administration of the iodine. Tablets containing definite amounts of iodine seemed to be the method of choice, but their use could not be made general or compulsory. Rochester, N. Y., tried putting iodine in the city water supply, but this did not seem practical, owing to the great waste. It was only natural that the addition of iodine to table salt should be tried, and in May, 1924, Michigan adopted a state law that all salt sold in the state should contain a certain amount of iodine. Goiter prevention was popularized by magazine articles, by instruction in schools and by medical lectures, until the laity has very generally gained the impression that small amounts of iodine can be taken with perfect safety. A circumstance that has tended to lead the profession to the unguarded use of iodine has been the apparent contradiction of the old idea fostered by Oswald and Crile that iodine acted unfavorably in cases of hyperthyroidism, by the discovery of Boothby and Plummer[5] that, when small amounts of iodine in the form of compound solution of iodine are given over a short period of time to patients suffering from hyperthyroidism caused by true hyperplasia and not by a toxic adenoma, they show a marked improvement, which is manifested both clinically and by the reduction of the basal metabolic rate. This discovery confirmed Marine's belief that iodine would cause the hyperplastic thyroid to return to the resting state, which in turn has been confirmed by Reinhoff, who studied the histology of the hyperplastic thyroid in man before and after the administration of iodine and found that the gland tends to assume the normal resting colloid state under iodine therapy.

COMMENT

All of the foregoing observations, at first glance, seemed to show that the problem of endemic goiter had been solved in a very easy and simple manner.

[5] Boothby, W. M., and Plummer, H. S.; J. Iowa M. Soc. **14**: 66-73 (Feb.) 1924.

However, as far as the use of iodized salt is concerned, the following factors must be taken into account:

1. Kimball and Marine worked entirely with children who, as a rule, are immune to the effects of iodine, whereas the use of iodized salt is generally not limited to children.
2. In Kimball's investigation, iodine was given periodically twice a year, thus allowing the thyroid a period of rest, whereas iodized salt is given continuously.
3. Kimball's conclusions were based on cases of simple and uncomplicated goiter, which, moreover, were observed frequently, whereas most cases of chronic goiter in adults are adenomatous in character, and these patients are not under observation while taking iodized salt.
4. Boothby and Plummer found the effect of iodine in cases of hyperthyroidism to be temporary and short lived and suitable only for the preparation of patients for operation. They found also that it was contraindicated in cases of hyperthyroidism due to toxic adenoma. Unfortunately, their work was eagerly accepted and not infrequently misinterpreted by enthusiasts, with the result that all kinds of goiter have been treated with compound solution of iodine. Many cases could be cited in which the thyroid gland has been hyperactivated in this way.

Both Dr. Crile and Dr. Phillips of this clinic are deeply interested in the subject, and they agree with me that, in view of the facts that have been cited, the community use of iodine may produce, especially in adults, an incidence of thyroid disturbance of greater economic importance than the evil it is designed to abolish, and that the general use of iodine will never be free from danger unless it is supervised by the medical profession, with safe standards for the administration of this potent drug. It seems to us to be necessary that a more thorough knowledge of what is known of the physiology and pathology of the thyroid gland be widely disseminated, lest a fundamentally sound movement for the prevention of goiter kill itself by its own boomerang. For this reason, it may not be amiss to append our own conclusions regarding the proper and safe use of iodine.

CONCLUSIONS

1. Iodine administered in small quantities, periodically, to children under the age of puberty is a very efficient preventive of simple goiter. Its use should be begun early and continued until puberty.
2. At the age of puberty, before iodine is prescribed, a careful examination of the thyroid gland should be made by a physician, to determine whether or not fetal adenomas are present. When adenomas are present, if iodine is used at all, it should be used with great caution, and in all cases the patient should be warned to discontinue the iodine should the usual symptoms of hyperthyroidism occur.
3. The continuous use of iodine over a long period of time should never be prescribed for adults, and when its periodic use is prescribed, frequent observations of the pulse and weight should be made.
4. Under no circumstances should iodine be administered to adults with fetal adenomas, either with or without symptoms of hyperthyroidism, except for a short period preceding operation. In the occasional case in which there is temporary improvement, the patient will be lulled to false security, and eventually a marked overactivity of the gland will result if the use of iodine is continued.
5. In the case of an adult patient who has a simple large colloid goiter or a large colloid adenomatous goiter without fetal adenoma, iodine sometimes has remarkably beneficial results and may be tried, but only with extreme caution, as it is this type of goiter that may become suddenly and overwhelmingly active, so that what appears one week to be a wonderful clinical result in every way may be a fulminating case of hyperthyroidism the next week, with a basal metabolic rate of plus 75 to 100, marked asthenia and a loss of from 5 to 10 pounds (2 to 4 Kg.) in one week.
6. If compound solution of iodine or iodine is administered in cases of exophthalmic goiter in which operation is not to be done, it should be discontinued or very greatly reduced when the basal metabolic rate is lowered and clinical symptoms improve. Continued use of the iodine will often again overactivate the thyroid gland.
7. Iodine should not be administered to a patient who has recovered after a thyroidectomy unless hypothyroidism exists, and even in these cases thyroid extract is usually more satisfactory.
8. Iodine is most efficiently administered and controlled in the form of chocolate tablets containing 10 mg. of organic iodine, or compound solution of iodine (Lugol's solution) when this is given under medical supervision. Periodic administration of iodine is always preferable.
9. Iodine may be administered in small doses to the pregnant woman for the prevention of goiter in the fetus. It is supposed to prevent fetal adenoma as well as colloid goiter. The amount of iodine required for this purpose is exceedingly small, and the best form in which to administer it is the chocolate tablet. Extreme caution must be used, as the thyroid gland is in a very unstable condition during pregnancy, and iodine may cause it to become hyperactive.
10. When overactivity of a thyroid gland has been induced by iodine, it usually does not subside when the iodine is discontinued, just as hyperactivity of the gland due to any other cause may not subside with the withdrawal of the exciting agent. In either case an operation is usually required.

In conclusion, I wish to state that this article is in no way a criticism of the principle of goiter prevention as a whole, for in this field lie untold possibilities for the future. The criticism is directed solely against the fallacious ideas regarding the use of iodine which have gained such wide publicity. Community administration of iodine disregards physiologic facts regarding the effect of iodine on the thyroid gland. The use of iodized salt, in particular, should be discontinued or limited absolutely to periodic table use by children under the age of puberty.

Euclid Avenue at Ninety-Third Street.

The Only Way to Joy and Enlightenment.—Sit straight and motionless, never inclining to the left hand nor to the right, never bowing forward nor turning backward. The ears should be in the same plane with the shoulders, and nose and navel in the same straight line. The tongue should stick to the upper jaw, while lip meets lip and teeth with teeth. Open the eyes not too widely yet not too slightly, and keep breathing through the nose. After composing mind and body in this way, you may take a long deep breath. Thus sitting motionless you may think of not thinking. Can you think of not thinking? This is thinking of nothing . . . it is the only way to great calm joy. This is unpolluted practice, and this is enlightenment.—Harada: The Faith of Japan, p. 89.

SALMON IN A DIET FOR THE PROPHYLAXIS OF GOITER*

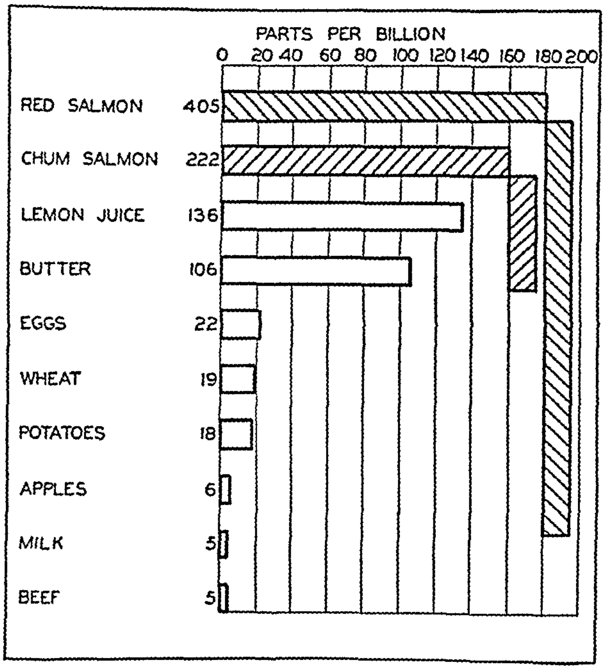
NORMAN D. JARVIS, M.S.
RAY W. CLOUGH, PH.D.
AND
ERNEST D. CLARK, PH.D.
SEATTLE

The researches of Chatin[1] on the distribution of iodine in nature, and his conclusion that goiter was due to a deficiency of this element, have been the subject of much discussion. It is now generally believed that iodine deficiency is the immediate cause of simple goiter, and that this disease is readily combated by a prophylactic treatment that supplies the amount of iodine necessary for the normal functioning of the thyroid. This may be accomplished by increasing the iodine in the diet by use of the proper foods, or by the administration of compounds of iodine.

Fellenberg[2] made a comprehensive study of the distribution of iodine in foods, beverages, soil and air. He found that the intake and excretion of iodine were approximately equal on a low iodine diet, but that, by the addition of iodine in such forms as cod liver oil, sardines, butter or potassium iodide, a positive iodine balance was obtained. McClendon and Hathaway[3] found that foods produced in goitrous regions contain less iodine than those produced in nongoitrous regions. They conclude that "the recession of goiter that has taken place in New York State during recent times is due to the greater transportation facilities for sea food into the inland regions."

Certain facts in support of the hypothesis that goiter is an iodine deficiency disease stand out in the observations of Keith[4] on goiter in the Pemberton Valley of British Columbia. This valley lies in the Coast Range Mountains, about ninety miles north of Vancouver. Every white child born in this valley had a goiter, and many white adults developed it within a few months after settlement there. Live stock suffered to such an extent from abnormalities of the thyroid that no litter of pigs lived more than one day after birth. There was a mortality of 90 per cent in calves and 85 per cent in colts from this cause. At the same time, no cases of goiter could be found among the inhabitants of an Indian village which had been located in the same spot in this valley many years before settlement by the white man; furthermore, these Indians have no knowledge or tradition of any of their tribe ever having had goiter. Clark and Pierce[5] show that the Indian is not racially immune to goiter. The pigs feeding in and around the village rarely suffer from myxedema or other diseases of the thyroid. In regard to the freedom of these Indians from goiter, Keith says, "Whilst considering the lack of goiter among these Indians I would like to draw attention to the fact that they eat a great deal of salmon . . . and annually cure thousands for winter use. Their pigs also eat the dead salmon washed ashore on the gravel banks of the stream. It is quite probable that the Indians and their pigs get enough iodine from the salmon to give their thyroids the necessary quantum of this element."

In the Great Lakes region, where goiter is endemic, butter is the most valuable local source of iodine.[6] We found that red and chinook salmon contain four times as much iodine as butter. There are other sea foods, such as lobster and oysters, that are higher in iodine content than salmon Indeed, seaweeds have the highest iodine content of any foodstuff.[7] But lobster and oysters are higher in price than salmon, and limited in supply. It has not yet been possible to induce the general public to use seaweed in any quantity American canned salmon is a staple food, produced in quantity; this, with its comparative cheapness and availability, renders it a very valuable food in a diet for the prevention of goiter The accompanying chart illustrates graphically the iodine content of two of the five species of salmon containing the highest and the lowest amounts of iodine, contrasted with that of milk, meat, eggs, vegetable and fruit products, highest in iodine.



Iodine in various food products (moist basis).

EXPERIMENTAL

When the iodine of a large number of food samples is to be determined, Tressler and Wells'[8] modification of Fellenberg's technic is most satisfactory. The method is capable of detecting very minute quantities of iodine. The apparatus required is inexpensive, and a considerable number of determinations may be made at one time.

The results of the analyses on canned salmon are given in the table. An attempt was made to secure samples from all the principal salmon canning districts. It will be noted that there is considerable variation between the species, and even some variation within the same species from different districts. In general, it has been found that as the salmon approaches the spawning stage, the iodine content of the flesh is decreased, apparently passing into the melt and roe, since these contain much more iodine than the flesh. The salmon used in such large quantities as food by the Indians of the Pemberton Valley were taken at this spawning stage. Even the flesh of these spawned-out salmon proved to be of great prophylactic value in an extremely goitrous region

The salmon of commerce is packed at an earlier stage of maturity, when the iodine content of the flesh is considerably higher.

The iodine content of fresh salmon is approximately that of canned salmon produced from the same region. We found no apparent loss in the canning operations. The amount of iodine added in canning salmon by the one-fourth ounce of salt used per pound can is negligible. Those edible portions of the body richest in fat have been found to be highest in iodine content. Fresh salmon is now packed in ice, or frozen, and transported considerable distances inland; but this use of salmon is small compared to that of the canned product.

The correlation between low iodine content in soil, water and food, and the incidence of goiter, is well established. Iodine metabolism experiments indicate that even in goitrous regions a properly selected diet will prevent goiter.[9] Salmon has at least equal grounds for consideration with milk products, fruits and leafy vegetables, the materials used in these experiments and found of value in the prophylaxis of goiter. Our results indicate a much higher iodine content in salmon than Fellenberg found in milk products, eggs, leafy vegetables or fruits. A considerable portion of the iodine in fruits is contained in such inedible portions as the rind and seeds. Canned salmon consists only of the edible portion, in which all the iodine may be utilized

It appears that the systematic use of sea foods which are rich in iodine would be of considerable benefit in treatment of simple goiter, or for its prevention in goitrous regions. Canned salmon, on account of its cheapness and availability, is particularly suitable, and should be included in the diet of patients.

DOSAGE OF TOXIN FOR ACTIVE IMMUNIZATION AGAINST SCARLET FEVER *

C. C. YOUNG, D.P.H.
AND
PAUL F. ORR, M D.
LANSING, MICH.

The method of immunization against scarlet fever recommended by the Scarlet Fever Committee requires five doses of 500, 1,500, 5,000, 15,000 and 20,000 skin test doses of toxin as a minimum, respectively, with an interval of one week between doses.[1] The requirement of five injections in addition to a diagnostic test before and after treatment is a serious drawback from a public health point of view. People are accustomed to three injections in typhoid and diphtheria immunization, and if scarlet fever immunization could be accomplished in this number it would be of great advantage.

This paper is a preliminary report of an attempt to determine whether it is possible to produce just as great, or greater, immunity from three as from five doses. This involved an effort to find the maximum dosage of scarlet fever toxin that could be administered without injurious effects on the individual, and the minimum dosage necessary to produce an immunity comparable to that resulting from an attack of scarlet fever. The effect of varying the time intervals between doses was also studied.

EXPERIMENTS

Dick tests were made on a group of persons, and those giving positive reactions were used for the immunization experiments. A small group was studied first to determine the safety of using a larger number of skin test doses than previously recommended, particularly in the second and third injections Following on the suggestive findings with this small number, a study was made of a group of ninety-seven persons, varying dosages and varying time intervals being used between doses. The dosage indicated as optimal in this group was then used in the immunization of a group of twenty-four susceptible persons.

Dosage and Time Interval— In all cases, the first dose was 500 skin test doses, since it has been found that initial injections of more than this amount frequently give quite severe reactions, such as headache, nausea and vomiting and also a scarlatiniform rash.[2]

[1] Official Communication, Scarlet Fever Committee, Jan 5, 1926

[2] Dick, G F, and Dick, Gladys H Results with Skin Test for Susceptibility to Scarlet Fever, J A M A **84**: 1477 (May 16) 1925.

The second injection varied from 2,500 to 5,000 skin test doses and was given one week after the first in one group and two weeks after the first in another group. The third injection varied from 10,000 to 40,000 skin test doses, and the interval between the second and third injections varied from one to three weeks.

Method of Injection.—Intramuscular injection of the scarlet fever toxin was employed after comparing this method with the subcutaneous one in groups of persons and finding, in general, a less severe local reaction from the intramuscular method. The toxin was injected deep into the deltoid muscle, a 1½ inch 22 gage needle being used.

Dick Tests After Treatment.—In order to determine the relative degree of immunity produced by the various methods of treatment, each person was tested with 1, 2, 5 and 10 skin test doses, respectively. A control test was also made on each person, a toxin with a potency of 5 skin test doses per 0.1 cc., which was heated at 100 C. for forty-five minutes, being used.

Toxin Used for Tests and Treatment.—Initial Dick tests were performed with a toxin standardized by comparison with a Dick toxin of known strength. It contained 1 skin test dose per 0.1 cc. of 1:2,000 dilution. For the final Dick tests after treatment, dilutions of this toxin were prepared so that 0.1 cc. contained 1, 2, 5 and 10 skin test doses, respectively. For the immunizing injections, Dick toxin was employed, which was tested before and after the period of experimentation, to check the number of skin test doses per cubic centimeter and to check the correctness of the calculated number of skin test doses in the various injections.[3]

Interpretation of Dick Readings.—The following interpretation is made in the recording of the Dick tests in the various tables: A reaction showing an inflammatory area of less than 1 cm. and greater than 0.25 cm. in diameter is considered ±, or a doubtful reaction. Reactions of 1 cm. and less than 2 cm., +; reactions of 2 cm. and less than 3 cm., ++; and those greater than 3 cm., +++. Tests showing an inflammatory reaction of 0.25 cm. or less in diameter are considered negative.

CLINICAL PATHOLOGIC REACTIONS FOLLOWING INJECTIONS OF TOXIN

The group of persons given from 20,000 to 41,000 skin test doses of toxin, as shown in table 1, had been given 500 and 1,500 skin test doses as the first and second immunizing injections. A one week interval elapsed between the first and second injections, and a three weeks interval between the second and third. The third dose of from 20,000 to 41,000 skin test doses was instituted following a preliminary series of injections in which the dosage had been increased up to 20,000 skin test doses without any injurious effects. It is to be noted from the clinical and laboratory findings that even with doses up to 41,000, no serious resulting pathologic condition developed. It was felt that the maximum dosage was being approached, particularly on account of the definite leukocytosis that developed following the larger injections.

---

[3] The toxin for immunization used in these series of experiments was furnished through the courtesy of Drs. George F. and Gladys H. Dick.

DEGREE OF IMMUNITY FOLLOWING THREE INJECTIONS OF SCARLET FEVER TOXIN

A detailed study was made of ninety-seven susceptible persons in whom the dosage as well as the time interval was varied between injections. The most striking feature noted was the decrease in the frequency and the severity of general reactions including rashes, when the time interval between injections was extended to two or three weeks instead of the customary one week period.

From the results obtained, 5,000 skin test doses for the second injection and 30,000 for the third injection appear to be the optimal dosage. Table 2 gives a summary of the immunity developed, as shown by the Dick test, in a group of persons in whom the third dose was varied from 10,000 to 41,000 skin test doses. This group had been given 500 skin test doses on first injection and from 2,500 to 5,000 on second injection. Relatively little difference is to be noted in the apparent immunity developed when 10,000 and 20,000 skin test doses are used; however, with doses over 20,000 there is a marked increase in the percentage of negative Dick reactions.

TABLE 3.—*Relative Degree of Immunity Following Three Injections of 500, 5,000, and 30,000 Skin Test Doses, Respectively, of Scarlet Fever Toxin*

Table 3 shows in detail the clinical reactions as well as the results of the intradermal test in a group of twenty-four persons who had received 500, 5,000 and 30,000 skin test doses, respectively, with a two weeks interval between injections. It is to be noted that general reactions were mild, and in only one instance in this group was a rash noted. Local reactions were recorded in centimeters, according to the area of redness around the point of injection. The results of this series of injections on the basis of the final Dick tests agree very closely with the results obtained previously and summarized in table 2.

SUMMARY

In a group of susceptible persons just as great or greater immunity was produced with three as with five injections of scarlet fever toxin.[1] The dosage suggested by the findings is 500, 5,000 and 30,000 skin test doses, respectively, with an interval of two weeks between injections.[4] (This method of immunization is now in routine use in Michigan state institutions.)

The time interval of two weeks is considered important, as there seems to be less systemic reaction and greater immunity produced than with the usual one week interval.

Clinical and laboratory findings showed no injurious effects on the subject following the relatively large dose of toxin used in the third injection.

This investigation is being continued on a larger scale. Considerable data are already at hand which are not available for publication.

---

[4] We have watched carefully for anaphylaxis when injections have been separated by two week intervals. Physicians in state institutions have reported only one case. A child, aged 10 years, showed marked urticaria, shortness of breath, prostration, and a temperature of 102 degrees. The symptoms all subsided in a few hours.

China's Two Systems.—China, which is one of the oldest civilized states of which we have any knowledge, possessed two systems of exercises, one which served as a training for war, and one for use in healing disease—in fact, a kind of medical gymnastics. In the oldest histories of the Japanese, Jews, Indians and Persians, physical exercises are also mentioned, and from Egypt we even have pictures showing the kind of exercises used there in the very early days.—Knudsen: A Textbook of Gymnastics, p. 1.

TREATMENT OF INFANTILE TETANY WITH A PARATHYROID EXTRACT

REPORT OF FOUR CASES *

LYNNE A. HOAG, M.D.
AND
HELEN RIVKIN, M.A.
NEW YORK

In January, 1925, Collip and Leitch[1] reported marked clinical improvement in a case of infantile tetany treated by the administration of an extract of parathyroid glands. The method of preparation and the properties of this extract were later more fully described by Collip and his associates.[2] Hjort, Robison and Tendick,[3] working independently, confirmed the efficacy of the extraction method and duplicated many of the animal experiments.

Since the time when a preparation of this parathyroid hormone became available for experimental study, only four cases of infantile tetany have been seen in the clinic. The data from this small number of cases are insufficient to justify any general conclusions. The primary purpose in presenting the figures is to make them available to other clinics at the beginning of the season when infantile tetany increases in frequency, thus eliminating for them some of the preliminary work on dosage.

METHODS AND MATERIAL

The plan of study was to determine the dosage of parathyroid extract effective for the alleviation and cure of infantile tetany.

The parathyroid extract used was parathyroid extract Collip,[4] the potency of which was indicated in units defined by Collip[5] as "one one-hundredth of the amount of extract which will produce an average increase of 5 mg. in the blood serum calcium of normal dogs of approximately 20 Kg. weight over a period of fifteen hours." The hormone was always given subcutaneously.

The progress of the cases was followed clinically and by the estimation of the serum calcium concentration. There is so much variation in the accuracy with which different observers can elicit signs of mechanical and electrical hyperirritability that the greater reliance was placed on the laboratory measure of improvement.

The blood samples were secured after a minimum fast of four hours. The method used to estimate calcium in the serum was essentially that of Kramer and Tisdall.[6] Definite time intervals in each step were adhered to, thus assuring greater uniformity in the series of determinations. The serum inorganic phosphorus was analyzed by the method of Tisdall,[7] by means of which average normal figures of nearly 6 mg. per hundred cubic centimeters are secured.

The diet in three cases consisted of dilutions of whole milk. One patient (F. R.) still received breast feedings.

REPORT OF CASES

Case 1.—A. P., a negro boy, aged 8 months, weighing 19 pounds (8.6 Kg.), was admitted to the ward, March 25, 1925, for treatment of a facial eczema. Ten days later, he exhibited an inspiratory crow and had a positive Chvostek's sign. The clinical diagnosis of infantile tetany was confirmed, April 6, when the serum calcium concentration was found to be only 6.7 mg. per hundred cubic centimeters.

Case 2.—F. R., a white boy, aged 6 months, weighing 17½ pounds (8 Kg.), was brought to the hospital, May 2, 1925, for the treatment of generalized convulsions, with all the usual clinical signs of tetany lacking. No more convulsions were observed after this time. Four days later, he showed positive physical signs of tetany and, May 7, the serum calcium concentration was 7.1 mg. per hundred cubic centimeters.

Case 3.—M. B., an undernourished white boy, aged 8 months, weighed only 11½ pounds (5.3 Kg.) when he was sent to the hospital, Aug. 6, 1925, for treatment of a moderately severe infection of the upper respiratory tract. Two weeks later, August 19, he had a mild convulsion, followed the next day by an inspiratory crow and a day later by a positive Chvostek's sign. August 22, the serum calcium was 7.5 mg. per hundred cubic centimeters.

Case 4.—J. B., a white boy, aged 4 months, weighing 10½ pounds (4.8 Kg.), was admitted to the hospital, Oct. 24, 1925, for regulation of diet. During the next few days he had several attacks of noisy inspiration accompanied by cyanosis. October 29, the serum calcium was 5.6 mg. per hundred cubic centimeters, but in spite of this low concentration, none of the signs of mechanical hyperirritability were elicited.

RESULTS

When treatment was begun in case 1 no data were available to assist in selecting the proper dose for infants. The danger from hypercalcemia in dogs was known and impelled the selection of an initial dosage which was insufficient to raise the serum calcium. The subsequent dosages were more successfully chosen and uniformly induced clinical improvement and increased the concentration of serum calcium. The mechanical and electrical hyperirritability had usually entirely disappeared by the time the calcium in the serum had reached 9 or 10 mg. per hundred cubic centimeters. When an inspiratory crow was present, it disappeared more slowly.

In three cases, recovery was complete. In cases 2 and 3, relief occurred in two days and the patients have remained free from symptoms of infantile tetany for seven and three and one half months, respectively. Patient 4 was also relieved in two days, but he relapsed into a condition of tetany when the parathyroid extract was discontinued at the end of this time.

Patient 1 had a severe complicating bronchopneumonia and died sixteen days after the cessation of treatment with parathyroid extract.

COMMENT

It seems quite evident that the parathyroid extract was responsible for the favorable results in cases 1 and 2 over the periods shown in the table, because no other treatment was given during this time. The experi-

mental value of case 3 was much decreased by the inadvertent exposure to ultraviolet irradiation about thirty-two hours before the third serum calcium determination. Falkenheim and Gyorgy[8] have said that the calcium in the blood is often temporarily decreased for many hours after the first ultraviolet exposure. It is felt that this treatment was not primarily responsible for the favorable outcome, because its repetition on the following day did not sustain the high calcium level in the face of a diminishing dose of parathyroid extract. In case 4 the administration of cod liver oil and calcium chloride for the period of a week may have influenced the results of the second and third courses of parathyroid extract, but no favorable effect was evident at the end of the seven days, as will be seen in the accompanying table

* In the table, Chv, Chvostek (facial phenomenon); per, peroneal reflex

The size of the doses used, the intervals between injections, the varying severity of the disease and the differences in weight and state of nutrition all introduced so many variables that no definite standard of effective dosage for the parathyroid extract is computable from this small series of cases. The response of the infants to this hormone showed the same individual variation that has been noted as occurring in dogs.[9] This may be seen in the following summary, intended to show the unit-time dose necessary to cause a rise of 1 mg of serum calcium:

Patient 1 required approximately 5 5 units per kilogram in nineteen hours at three hour intervals

Patient 2 required approximately 5 2 units per kilogram in thirty-nine hours at eight hour intervals

Patient 3 required 6 units per kilogram at intervals of from nine to twenty-two hours over a total period of forty-eight hours

Patient 4 required in three successive series of parathyroid extract (1) 8 7 units per kilogram in twenty-eight hours at six hour intervals; (2) 10 8 units per kilogram in sixty-three hours at twelve hour intervals, and (3) 5 6 units per kilogram in twenty-eight hours at six hour intervals[10]

It is fairly evident that the greatest unit effectiveness is secured from this hormone when the total dose is given at fairly frequent intervals (from four to six hours) over a short period of time (from eighteen to thirty-six hours).

On the basis of the foregoing figures, it seems safe to recommend an initial dose of about 5 units per kilogram of body weight for each milligram of calcium rise desired, to be given subcutaneously at four to six hour intervals in from twenty-four to thirty-six hours. This is an arbitrary recommendation, and the effect should be observed by means of serum calcium determinations.

The fraction of the original total dose that is necessary in each twenty-four hours to sustain this normal calcium level cannot be predicted from the foregoing data It apparently varies from about one-eighth to one-fifth, and naturally decreases as the patient improves.

The effect of the abrupt omission of the hormone treatment was apparently dependent on the stage of the disease Omission early in the course (case 4) allowed a relapse, but this was not so evident on withdrawal of the extract after improvement had been maintained a few days.

[8] Falkenheim C, and Gyorgy, P Zur Besthrahlungstherapie der Tetanie, Jahrb f Kinderh **107**: 201 210 (Nov) 1924

[9] Collip and others (footnote 2) Hjort, Robison and Tendick (footnote 3)

[10] Since the submission of these data, we have had the opportunity to administer parathyroid extract as the initial treatment in two more cases of manifest infantile tetany Case 5, A T, aged 4 months (5 Kg), required 4 units of extract per kilogram to cause each 1 mg rise in serum calcium, when given in thirty seven hours at six hour intervals in conjunction with a total dose of 2 Gm of calcium chloride by mouth Case 6, B M, aged 3 years (12 7 Kg), entered the hospital during his third attack of infantile tetany He required 9 units of parathyroid extract per kilogram to cause each 1 mg rise in serum calcium, when given at four to six hour intervals during a period of forty eight hours

A significant degree of hypercalcemia was not produced in any case.

SUMMARY

The subcutaneous administration of proper doses of parathyroid extract-Collip in four cases of infantile tetany caused rapid improvement in symptoms and signs and a prompt return to normal of the serum calcium concentration in from twenty-four to forty-eight hours. The continued daily administration of suitable fractions of this initial dose maintained this clinical and laboratory improvement. It is felt that a safe tentative dose is about five units of parathyroid extract per kilogram of body weight for each desired rise of 1 mg. of serum calcium, the total amount to be distributed over a period of from twenty-four to thirty-six hours at four to six hour intervals. The individual reaction is so variable that the effect should be estimated by means of repeated serum calcium determinations.

Clinical Notes, Suggestions, and New Instruments

OXYGEN TREATMENT OF MALIGNANT EDEMA

R. P. Roantree, M.D., Elko, Nev.

In reviewing the literature on this subject, I can find no mention of a patient treated in this manner or a description of a simple apparatus that may be used in injecting the oxygen.

REPORT OF CASE

P. J., a muscular man, aged 26, entered Elko General Hospital, Sept, 6, 1924, complaining of a revolver wound of the left elbow. His past and family history are irrelevant. The injury occurred between 9 and 10 p. m., Sept. 3. The arm was cleansed and the wound irrigated with compound solution of cresol. The bullet had been removed from beneath the skin at about the middle of the mesial side of the arm by a layman. The wound was irrigated with compound solution of cresol twice on the 4th and three times, September 5.

The pulse rate was 85, the temperature, 99.6 F., and respirations, 22. There was a bullet wound in the palmar surface of the left forearm, at the junction of the upper and middle thirds. The bullet had been removed from the posterior surface of the left arm at the junction of the lower and middle thirds. The arm from well above and below the wounds was greatly swollen and was of a peculiar bronze color. There was crepitation about the wound both of entry and of exit, and this extended well up toward the left axilla. Roentgenograms revealed no bony injury. The films disclosed areas of decreased density beneath the wound both of entry and of exit, which were diagnosed as gas within the subcutaneous tissue. They appeared to be about 1 inch (2.5 cm.) below the skin surface. The gas beneath the wound in the forearm was small in amount and well localized. That beneath the wound in the arm was greater in amount and had dissected proximally to the axillary fold.

The urine was normal. A smear from the wound revealed a gram-negative bacillus. Unfortunately, no cultures were made.

Two consultants confirmed the diagnosis of gas bacillus infection. A disarticulation at the left shoulder was advised. This was carried out at once. No gas was encountered during the disarticulation. All subcutaneous soft tissue was removed as far proximally as possible.

September 7, the temperature was 100, the pulse 120, and respirations, 24. Careful palpation about the wound revealed no crepitus.

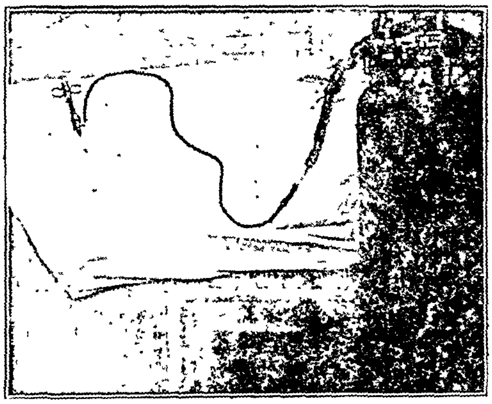
September 8, the temperature was 100, the pulse 120, and respirations, 20. There was some crepitation felt extending downward and anterior to the lower angle of the wound. Oxygen was injected subcutaneously at this time.

September 9, the oxygen injection was repeated.

September 13, there was a large discharge of bloody serum. The wound margins separated slightly because of tension caused by the oxygen. Crepitation persisted until September 29. Aside from the foregoing irregularities, the patient made an uneventful recovery and was discharged, September 29.

METHOD OF INJECTION

The usual large tubing on a Heidebrink gas-oxygen anesthesia machine was reduced by the use of rubber tubing to fit the one way valve on a Dunn's local anesthesia syringe, as shown in the illustration. The skin was prepared with iodine and alcohol for a liberal distance about the crepitant area and wound. The gas bag was filled with oxygen. The needle was introduced down to the ribs and intercostal muscles at a distance of about 6 inches (15 cm.) from the area of crepitation, and each layer injected as the needle was withdrawn. This was repeated until the crepitant area had been completely circumscribed. Following this, the interior of the circle was injected until the skin was tightly distended.



Heidebrink gas-oxygen anesthesia machine with Dunn's local anesthesia syringe attached.

SUMMARY

Results obtained in a single case are not conclusive. However, this experience leads one to believe that oxygen may be injected subcutaneously in large amounts without serious disturbance. This case is reported with the hope that it will stimulate the use of this method to determine its efficacy. The procedure has the following advantages over amputation or free incision: It saves the extremities; it may be used on all areas of the body; there are no resulting scars and less possibility of secondary infection; it may be carried out without anesthesia or the shock and pain accompanying several incisions.

SEVERE LACERATION OF HAND WITH TRAUMATIC AMPUTATION OF TWO FINGERS*

Martin J. Loeb, M.D., New York

History.—A boy, aged 8 years, was run over by a truck, June 29, 1923. Shortly after, on admission to the hospital, he was seen by two able surgeons, who happened to be in the institution, and who advised an amputation of the hand above the wrist. I mention this fact, not in disparagement of these men, but merely to give an idea of the severity of the trauma. I did not see the hand until the boy was under narcosis and ready for operation, two hours after the injury. My decision as to procedure was therefore immediately made.

---

* From the service of Dr. Martin Rehling at the Bronx Hospital.

* Read before the Bronx County Medical Society, Jan. 23, 1924, at the New York University Clinical Society, March 7, 1924, and at the Eastern Medical Society, May 9, 1924.

Preoperative Findings.—The metacarpal bones of the ring and small finger of the right hand were broken, together with their attachments of muscles and nerves. The skin of the palm of the hand, together with the underlying palmar fascia, was torn off the hand, and these and the two traumatically amputated fingers were hanging from the hand, attached only by the web of skin between the ring and middle finger. The small adductors of the thumb were torn across, as were two tendons of the flexor sublimis of the middle and index finger (fig. 1).

Procedure.—The hand was thoroughly scrubbed with soap and water, followed by ether. Tincture of iodine was generously applied several times and each time washed off with alcohol. The adductor brevis pollicis was sutured, as were the sublimis tendons of the remaining fingers. The ring finger was denuded of its skin, and this piece of skin, which was attached by the web to the dorsal surface of the hand, was placed across the lower part of the palm (fig. 2). As this was done, the mass held by this bridge of skin fell off (fig. 1). The rest of the wound was left to granulate.

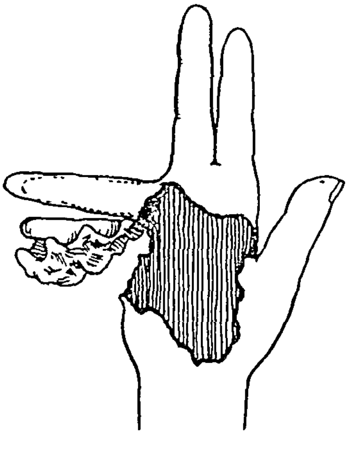


Fig 1.—Traumatic amputation of the ring and small finger of the right hand through the metacarpal bones: The skin of the palm as well as the underlying palmar fascia was torn off; some of the tendons were severed.

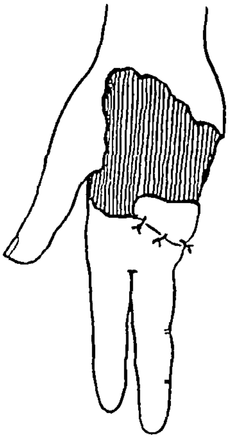

Fig. 2.—Skin of ring finger placed across palm; tendons sutured.

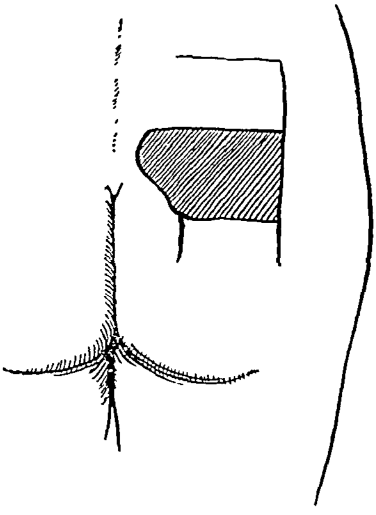

Fig 4.—Denuded area from which graft was made; incisions.

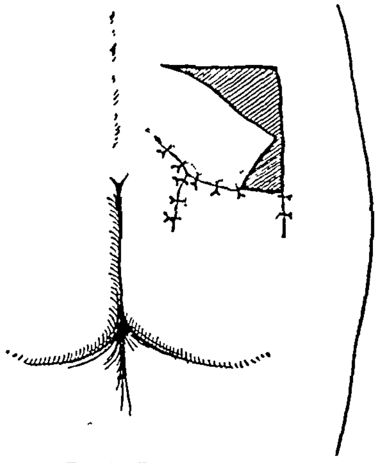

Fig. 5.—Bringing down of flap.

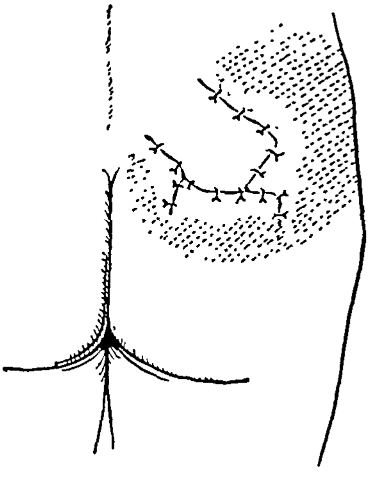

Fig. 6.—Undermined skin from abdomen and side brought backward to meet flap, defects of buttock completely covered.

July 20, the second operation was performed in the following manner: A pattern was made of the denuded area of the palm of the hand and this pattern marked out on the skin of the right buttock. The skin was then cut above and below about 5 inches in width and 3½ inches in length. The hand was then placed on the back, palm facing backward, and brought through this pocket of skin. The button-hole was made in the skin through which the thumb was taken through so as to have the denuded area between the thumb and the index finger in contact with the skin of the buttock. The patient was then placed in a plaster-of-paris jacket to keep his hand immovable in that position. The skin was attached at its edges to the palm of the hand with interrupted silkworm-gut sutures. A window was cut through the plaster of paris so that the hand could be dressed, if necessary (fig. 3).

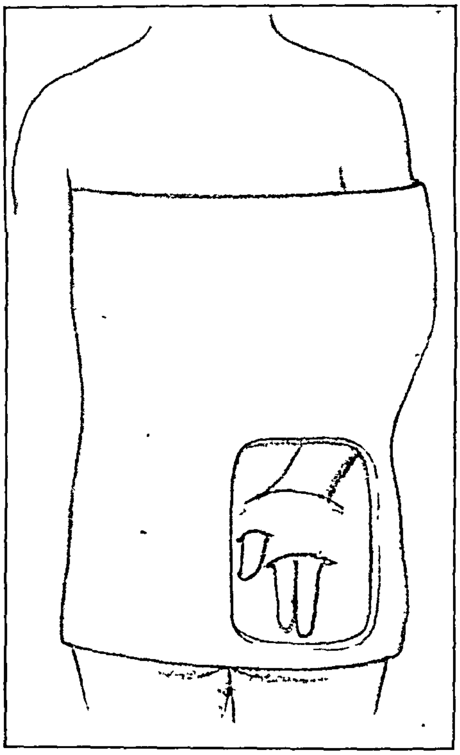

Fig. 3.—Skin of buttock undermined; denuded hand placed underneath; special opening made for thumb to cover denuded web between thumb and index finger; plaster jacket applied.

July 31, the wound was exposed through the plaster-of-paris window and the right edge of the skin lying over the palm was severed under local anesthesia (fig. 3).

August 10, the rest of the flap attached to the inner side of the body was severed, the hand was removed from its plaster encasement, and the skin was cut farther away from the edges of the wound to allow for contraction. The hand was bandaged and the patient turned on his abdomen. The area found to be denuded on the back was 4 by 5 inches, or about 20 square inches of surface. The flap was cut upward from the outer edge of the wound for about 5 inches. Then this incision was carried backward toward the spinal column, giving a quadrilateral flap of skin with an attachment toward the spinal column The skin of the abdomen was undermined, as well as the skin of the buttock. This flap was brought downward and attached partially to the skin of the buttock while the skin of the abdomen was brought backward as far as possible to cover up the defect that was made by the transplanting of the quadrilateral flap (figs 3, 4, 5 and 6)

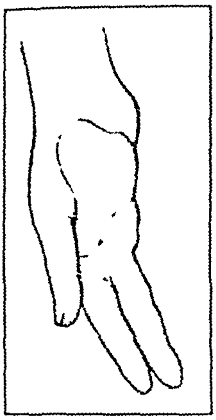

Fig. 7 — Hand as it appears now.

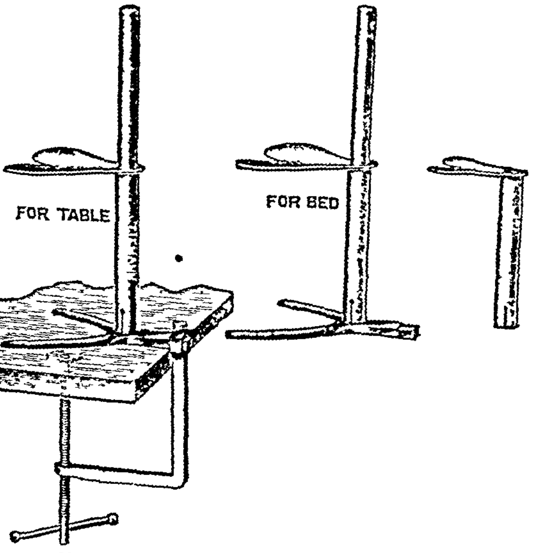
Result—Figure 7 shows the result of the graft. I might add that the patient has excellent function, the palm being wider above because I did not remove the upper fragments of the metacarpal bones, thus adding greater utility. The adduction of the thumb is perfect, and since I took very little adipose tissue with the skin, the cosmetic result is as good as the function

1475 Grand Concourse, Bronx.

MODIFIED HIP REST

David R Telson, M D, Brooklyn

The illustration shows a hip rest which can be applied with equal ease to the operating table, the examination table or any table found in the patient's home. The throat of the instrument is made deep enough to allow its application within the baseboard of the dining table Therefore, the necessity of clamping the rest on the very edge of the table, outside the baseboard, is done away with The clamp is detachable and, if need be, the rest can be laid flat on a board in bed. The pelvic plates are unique in being shaped to fit the sacrum, thus obviating the usual gap between the spica and the patient, posteriorly.



Hip rest that can be used for bed or table.

734 Ocean Avenue.

Special Article

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M D
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1285)

DOMESTIC MEASURES OF DOSAGE

On account of the ignorance of the average layman in regard to weights and measures, it is customary to direct patients to employ, for the administration of medicines, domestic measures with which they are familiar, such as

1 drop (abbreviation gtt Latin gutta)	About 0 05 cc[46]
1 teaspoonful	About 5 00 cc.
1 dessertspoonful	About 10 00 cc
1 tablespoonful	About 15 00 cc
1 wineglassful	About 50 00 cc
1 teacupful	About 100 00 cc
1 tumblerful	About 250 00 cc
1 knifepointful	About 1 to 2 Gm

Because of greater convenience in calculation of metric quantities, it is admissible to consider the teaspoonful 5 cc and the tablespoonful 15 cc. In view of the variability of all these measures, this is quite as correct as figuring on a 4 cc. teaspoonful, an 8 cc. dessertspoonful and a 16 cc. tablespoonful, or a wineglassful at 60 cc and a cupful at 120 cc., as is done when one uses the old system of weights and measures. In view of this inexactness of the domestic measures, it would be desirable to have them replaced by graduated medicine glasses

The size of the dose of the finished medicine, whether teaspoonful, dessertspoonful or tablespoonful, depends mainly on the solubility of the medicament. After this has been determined, the number of doses should be decided on, keeping in mind, first, the rule to prescribe generally enough to last from one visit to the next, and, secondly, to have the prescribed medicine just fill a bottle. It looks better. Hence we must know the various sizes of medicine bottles carried in stock by our druggists; they range as follows: 4, 8 and 16 cc (1, 2 and 4 fluidrachms) and 30, 60, 90, 120, 180, 240, 360, 500 and 1,000 cc. (1, 2, 3, 4, 6, 8, 12, 16 and 32 fluidounces) It is to be regretted that the druggists of this country do not yet carry a stock of metric prescription bottles However, we can hardly subject the average druggist to the hardship of keeping two complete assortments of bottles on hand. How soon pharmacists will change their stock of bottles, so as to carry only metric bottles, depends entirely on how soon physicians generally discard the old system.

As, in prescribing solutions, it would be rather difficult to estimate just how much of the vehicle is needed to fill a bottle of a certain size, for the solute replaces some of the solvent, it is customary simply to direct the pharmacist to use a sufficient quantity of the vehicle to make up the total volume desired; this is simply expressed by writing: "to make," which is then followed by the figure expressing the total volume. If, for instance, one wishes to prescribe fifteen doses of 1 Gm. of potassium bromide with peppermint water as the vehicle, and decides that a teaspoonful is to be the dose of the finished product, one writes:

---

* This is the eighteenth of a series of articles on "The Technic of Medication" When completed the articles will be assembled in book form

[46] Only approximately correct in the case of aqueous fluids (see discussion on "Drop Dosage").

℞ Potassium bromide.............................. 15 Gm.
Peppermint water.. ....to make 60 cc.
Label: Teaspoonful in water every two hours

Had the phrase "to make" been omitted in this prescription, the volume of the finished product would exceed 60 cc. somewhat, as the dissolved salt occupies some space; and consequently each teaspoonful would contain a little less than the desired amount.

If the rule followed is to have the prescribed mixture aggregate just a bottleful, the number of doses prescribed is generally not convenient for figuring in the metric system. One way of overcoming this is to disregard the rule as to the prescribing of a bottleful, and to order 50, 100, etc., cc. mixtures, letting the druggist dispense them as best he can. Thus, for a time, patients would obtain only partially filled medicine bottles; and after a while the druggists would find it to their advantage to carry in stock metric prescription bottles.

For those who have learned the doses of medicines in the old system, and who desire to write metric prescriptions—as all should—the application of the assumption that 1 Gm. or cc. = gr. xv or ℳ xv[47] permits the following convenient rule to be formulated: Substituting for the number of grains or minims of the dose the same number of grams or cubic centimeters will give fifteen doses in metric terms. By this rule one is enabled to prescribe, without any difficulty, an ordinary bottleful, as 60 cc. (fifteen doses of 60 minims, or a teaspoonful) or 240 cc. (fifteen doses of 240 minims, or a tablespoonful) will fill a 2 or an 8 ounce bottle, respectively.

COMPUTATION OF "PER CENT" SOLUTIONS

It is easy to compute the strength of "per cent" solutions in the metric system. To prescribe 1 : 1,000 solutions, one simply uses as many milligrams of the drug as cubic centimeters of solution are desired: for 0.001 : 1 equals 1 : 1,000. Hence, to prescribe a 1 ounce bottleful of 1 : 1,000 solution, one uses 30 mg. (written 0.030 Gm.) of drug to 30 cc. of solvent; for a 4 ounce bottle (120 cc.), one uses 0.120 Gm.

A simple mathematical trick for quick calculation on making higher from lower dilutions is described by Fletcher:[48]

> The average civilized man can count two quite easily; for instance, he knows how to prepare a 40 per cent from one of 80 per cent by taking one part of the latter and making it up to two parts by adding an equal quantity of the diluent. This is the same thing as taking 40 parts and adding sufficient diluent to make 80. What is not generally realized is that all other dilutions can be prepared on the same *principle*; for example, a 30 per cent solution can be made from one of 50 per cent strength by taking 30 parts of the latter and making it up to 50; or a 40.25 per cent solution can be prepared from one of 79.5 per cent by taking 40.25 cc. of the latter and adding sufficient diluent to make 79.5 cc. That is to say, an x per cent solution can be prepared from a y per cent solution by taking x cc. of the latter and diluting it sufficiently to make y cc.
>
> The preparation of the other fractional dilutions is equally simple. As every one knows, a 1 in 10 solution (written 1/10) can be made from a 1 in 5 (1/5) solution by taking 5 parts of the latter, and diluting it up to 10 parts, but it is not generally known that all dilutions can be prepared in the same way; that, for instance, a 1/97 dilution can be made from a 1/8 dilution by taking 8 parts of the latter and making it up to 97. In short, a $1/x$ solution can be prepared from a $1/y$ solution by taking y cc. of the latter and adding sufficient diluent to produce x cc.

By this method the medical man can not only calculate quickly but do it "in his head."

Blacklock[49] calls attention to Stephens and Christopher's simple formula which shows the amount of diluting fluid necessary to add to 1 volume of fluid of percentage x in order to reduce that volume to the desired percentage y. The formula is $x/y - 1$, in which x represents the original percentage and y the desired percentage. Thus, to dilute a solution from 20 per cent to 5 per cent, one adds to each volume of solution $20/5 - 1 = 3$ of the diluting fluid.

The following formula can be used when it is necessary to prepare specified volumes of lower percentage from higher percentage:

> To prepare a specified volume z of a y per cent solution from an x per cent solution, take of the latter $\frac{z \times y}{x}$ volume and make up to z volume with diluting fluid. Example: To obtain 12 cc. of a 24 per cent solution from an 80 per cent solution, take of the latter $\frac{12 \times 24}{80} = 3.6$ cc. and make up to 12 cc. with diluting fluid.
>
> Fractional Dilution: To prepare a specified volume z of a $1/y$ dilution from a $1/x$ dilution, take of the latter $\frac{z \times x}{y}$ volume and make up to z volume with diluting fluid. Example: To obtain 60 cc. of a 1/100 dilution from a 1/10 dilution, take of the latter $\frac{60 \times 10}{100} = 6$ cc. and make up to 60 cc. with diluting fluid.

DILUTION OF DOSE BEFORE TAKING

Nearly all medicine should be freely diluted before taking: for, properly diluted, it will taste less and it will be better borne by the stomach. In case of medicines of very disagreeable taste, it is better to dilute with only a moderate amount of fluid, so as to lessen the quantity of nasty liquid that must be swallowed. On the other hand, the more irritating the medicine, the more it should be diluted. In the interest of economy, it is well to prescribe a spoonful just large enough to keep the solids in solution, and direct the patient to dilute the medicine just before taking the dose. In many instances, water suffices as the diluent. If one wishes to favor absorption, hot water or carbonated water may be used. To lessen tendency to produce nausea or vomiting, ice cold water, or, better still, ice cold carbonated water may be used. Because of the importance of carbonated water as a diluent for medicines, it is well to be familiar with all the various methods of imparting effervescence to medicines. The simplest of these is the use of carbonated water from siphon bottles (the so-called siphon seltzer). The official solution of magnesium citrate is an example of another way of charging medicament with carbon dioxide. This is a lemonade-like drink containing a little over 5 Gm. of magnesium oxide made effervescing by carbon dioxide under pressure. Of course, of this solution not less than a bottleful (360 cc.) should be prescribed. Effervescing powders prescribed like the seidlitz powders and effervescing salts (previously discussed) are other examples of how the same result may be obtained in a still different manner. Finally, the patient may add lemon juice just before taking his dose of medicament containing bicarbonate.

---

[47] In writing quantities in the old system, we must be very careful to use a distinctive method, because of the great similarity of the signs Gm. and gr. The symbol for grain, written with a small initial letter, should precede the number, which is given in Roman *numerals*. If there are fractions, these should always be stated as common fractions, never written as decimals even if they might be.

[48] Fletcher, William: Lancet 1: 223 (Jan. 29) 1921.

[49] Blacklock, B.: Lancet 1: 377 (Feb. 19) 1921.

Lemonade sometimes makes a pleasant diluent for medicine. Effervescing magnesium sulphate (N. F.) is, for instance, best given in an ice cold lemonade. Other diluted fruit juices, such as orangeade and grape juice, may also at times be used to advantage. Soup enables one to give medicines of purely saline taste, such as bromide, even without the patient's knowledge that he is getting medicine, if the medicinal salt is used instead of cooking salt. Sodium iodide may be added to sodium chloride and used in the salt shaker to season one's daily food, as in the treatment and prevention of simple goiter. Coffee and cacao may also be used as a disguising diluent, most especially of medicines of a moderate degree of bitterness, such as senna. Among colloidal diluents, milk is of especial value not only for disguising taste but also for lessening irritation. One must, however, be careful not to prejudice patients, especially little children, against such an important food as milk.

DOSAGE OF DRUGS

Next in importance to the selection of the proper drug, or even quite as important, is the determination of the proper dose. The proper dose is just enough to produce the desired effect in the patient for whom the medicament is intended with a minimum of undesired side-effects. Some remedies act differently in different doses, a small dose sometimes having exactly the opposite effect from that of a large one. The Pharmacopeia and the National Formulary give, in connection with each article that is likely to be used internally, the average dose for adults. These doses must not be regarded obligatory; they are merely intended as a guide to those unfamiliar with the drug or preparation. A physician may give less or more, according to his judgment; for the dose of a remedy must be varied in the same manner that the size of a coat must be varied to fit each person.

The "physiologic" dose is that amount which will produce slight but distinct symptoms in a normal person; in the textbooks it is generally stated as the maximum dose. When a powerful remedy is being given for the first time, it is better to begin with a smaller dose, the initial or minimum dose, unless the urgency of the case demands that a large dose be given. Cases occur in which the "maximum dose" of the textbooks is exceeded with positive benefit to the patient. The only dose that should not or only exceptionally be exceeded, and then with the greatest caution and every possible safeguard, is the minimum lethal dose, the smallest quantity known to have produced death in a human being. A toxic dose is one capable of producing marked derangement of the functions of the body.

The dose given in the textbooks is considered proper for adult males in the prime of life; the medicament, unless otherwise specified, is to be given by the mouth. There are many conditions that necessitate modifications of this dose.

1. *Age and Sex.*—The same amount of drug distributed through the tissues of a very large person must receive a greater dilution and hence have less effect than if distributed through the tissues of a very small one. Thus, the dose is nearly proportional to the weight, although in such calculations the weight of adipose tissue would have to be deducted, for fat is an inert tissue and does not count; similarly, allowance has to be made for dropsies. Women usually require relatively smaller doses than men, not only because they are generally smaller but also because they are more sensitive than men.

There is great difference between the weight of the child and that of the adult. Partly for this reason, and partly because certain tissues of the child differ in their susceptibility to drugs from those of the adult, the necessity arises for a very careful adjustment of the dose in the case of children. We must realize in this connection that there is no universally applicable rule for determining the dosage for children as a certain proportion of the adult's dose; for "the child is not merely a small adult," but has reactions to disease as well as to remedies that differ from those of the adult. This is indeed the justification for the existence of pediatrics as a specialty, and the reason why a pediatrician, knowing just what dose to give to a child irrespective of the dose of the adult, may have much better success than the physician who just goes by rule of thumb. Still, some such rule is necessary to serve the beginner for general guidance. Probably the simplest rule for the prescriber in the metric system is a modification of Cowling's rule, according to which the adult's age is taken as 25, and each year that the child has commenced as an even part of 25. According to this rule, for instance, a child of 4 (having commenced its fifth year) would require five twenty-fifths, or one fifth, of the adult dose. As it is often easier, instead of dividing by 25 to multiply by 4 and divide by 100, we may arrive at a child's dose by multiplying the adult dose by the child's age multiplied by 4, and then to divide by 100, which is done by simply writing the decimal fraction. Thus, if the adult dose of a substance, say sodium bromide, is 1 Gm., its dose for a child of 3, according to this rule, would be $\frac{4 \times 4}{100}$ or 0.16 Gm.

A still simpler way of applying this rule consists of adding to 100 cc. (which contains approximately twenty-five doses) as many adult doses as the child has years in its age plus one. Therefore, to 100 cc. (a 3 ounce bottle) we would add 4 Gm. of sodium bromide for a child 3 years of age.

As Cowling's rule errs somewhat in the direction of generally apportioning rather too small a dose, it will be seen that to apportion dosage for infants under 1 year, we may safely calculate the months as years and divide the result by 10 (instead of 12). Hence, for a child 3 months old, the dose of a substance whose adult dose is 1 Gm. would be one tenth of the dose calculated for a child 3 years old, or 0.016 Gm.

All these arbitrary rules require, however, modification in case of certain drugs. Thus, children are very susceptible to opium, which must be given in doses much smaller than those of the formula; while arsenic, bromide, belladonna and purgatives are usually well borne by children, and relatively large doses must be prescribed. Antitoxin has to be given in almost as large a dose to the child as to an adult, for it is in relatively much greater need of it than the adult, being so much less able to develop its own antitoxin.

As old age approaches, it is advised to reduce the dose somewhat, and to give to patients from 70 to 80 years of age about three fourths of the adult dose; after 85, about one half. There are exceptions to this rule, also; for old persons generally bear opium and stimulants very well, and often need large doses of purgatives.

SCIENCE IN EVERYDAY MEDICINE

In the introductory chapters of a recent volume on scientific research and human welfare,[1] the writer remarked that nothing is more exasperating than to be compelled to witness a great tragedy which we know could be prevented if we could only do the right thing. Probably physicians in earlier times felt much the same way, he adds, when they saw their patients die by scores during some epidemic with which they were powerless to cope. Until the last half century, all who had to do with disease were so bound by the bonds of ignorance that they were well nigh powerless. For its own progress, one of the foremost ever present needs of medicine is the acquiring of new knowledge. Before rational progress in therapy can come about, the mystery of maladies of unknown pathogenesis must be dispelled. Physicians in the past were able only imperfectly to cope with infection and disease. It was not until trained research workers devoted themselves to a study of the fundamental causes of disease that real significant progress was made; more was then accomplished in fifty years than in all the past history of the world. This salient fact of the importance of the search for truth, the goal of investigation, needs to be reiterated frequently lest the medical investigator be allowed to lapse into indifference owing to the lack of appreciation and support from his so-called practical colleagues.

For this reason, too, it seems worth while to point repeatedly to the varied illustrations of what scientific investigation means for human welfare through medical enlightenment. A recent issue of The Journal will serve to furnish examples. Thus, Brown[2] of the Mayo Clinic has called attention to the fact that, as the outcome of studies in the domain of gastro-enterology, infestation with *Endameba histolytica* is far more common in the temperate zone than is generally suspected. As the endameba is transmitted by food and water, new problems attend the use of uncooked food and the drinking water supply in certain sections, particularly when one realizes that a single clinic has identified the parasite in 533 cases in five years under conditions in which only a small proportion of all the patients had stool examinations. Brown has formulated the advice that repeated examinations of stools are essential to the diagnosis of all forms of dysentery, and has pointed out requisites for correct differential diagnosis and probabilities of successful treatment. No amount of ordinary "bedside observation" could have established the important facts recorded in Brown's research.

Again, there is a record in the same issue[3] of the outbreaks of botulism within the past year. In the study of this the bacteriologist has awakened the medical profession to the reality of the menace, the quarters whence it may be expected, and the nature of the toxin. The immunologist has brought antitoxic treatment rapidly within the realm of successful accomplishment. This is a contribution not of the "practitioner" but of the laboratory investigator in relation to a danger not sufficiently appreciated heretofore. Intuition cannot successfully attack botulism. Similarly, the latest report of Graham[4] and his colleagues at the Washington University Medical School, St. Louis, on the development of their studies on cholecystography illustrates the dependence of a practical diagnostic technic on patient preliminary investigation. There was the long search for a substance, sufficiently harmless for introduction into man, that would be excreted by the liver in the bile and could be visualized through roentgenographic means. The organic chemist, the physiologist and the physicist were brought to the aid of practical medicine. The description of the possible application of a single new substance, sodium phenoltetraiodophthalein, in simultaneous cholecystography and tests of both hepatic and renal functions is the culmination not of accidental discovery but of prolonged laborious effort in several fields of scientific endeavor.

It is significant of the growth of the research spirit in this country that careful inspection of almost any issue of The Journal would disclose such illustrative helpful promotions of medical progress as have just been reviewed. Lee[5] has remarked that the altruism of men of medicine has become proverbial. Their heroism in investigating and treating disease is often put to the test, and is rarely found wanting. Their ideals are high, and they can be trusted to do what is within their power to put an end to the ills of suffering humanity. Yet it should be borne in mind that scientific medicine unaided has a well nigh impossible work before it. If it is to accomplish the final banishment of disease, Lee concludes, it must have the sympathetic cooperation and encouragement of mankind, in whose interests it continually labors.

DALLAS HOSPITALITY

When registration closed at the Dallas Session of the American Medical Association, April 23, with a total of 4,179 physicians in attendance at the session, the high point was reached for any medical convention ever held in the southern part of the United States. This climax marked the achievement of a pinnacle not only in numbers but also in scientific progress, hospitality and attention to the economic problems of medical practice.

The meetings of the House of Delegates were characterized by earnest and harmonious consideration of the problems of the day. The work of the Veterans' Bureau, the current litigation and legislation on alcohol, the presentation of expert opinion evidence in our courts of law, and the problems of medical and nursing education held attention equally with the more intimate details of organizational affairs within the American Medical Association.

The technical exhibits were beautifully housed in a structure that might well have been built specifically for the purpose. Under the same roof the scientific exhibit and the motion picture show attracted the attention of thousands of physicians, who were able to hear at first hand the results of recent investigations in laboratory medicine and to complete in the course of the week a rapid-fire course of postgraduate medical instruction. The majority of the scientific sessions of the various sections likewise were held in this structure. The clinics of Monday and the papers of the last three days attracted large audiences. Many of those in attendance expressed satisfaction with the acoustic properties and the comfortable arrangements of the halls devoted to this purpose. Of special significance in the scientific programs were symposiums on the respiratory conditions of childhood, on the surgery of the sympathetic nervous system, and on the disturbances of the heart, which outlined clearly the present status of knowledge in these fields. At the same time, the newer discoveries of medicine and of surgery relating to the use of new medicaments, of roentgen-ray, radium and physical therapy, and of new methods for the control of hypertension were not neglected. Finally, the programs of the scientific sections were marked by an unusual number of addresses devoted to methods of organization and to promulgation of the benefits of medicine on a large scale to the public.

Above all else, the Dallas Session was characterized by a form of interest and entertainment that has become proverbial under the name of "Southern hospitality." It seemed, indeed, that every citizen of the community had schooled himself in the thought that the week of April 19-23 was to be devoted to the care of the visiting physicians and their guests. The clubs, department stores, hotels, taxi-drivers, street-car employees—in fact, all lay organizations and individuals who came into contact with those attending the session—seemed to be willing to do everything in their power to see to it that the conventionist was served in the most exemplary manner. The organization of such extensive luncheons as the barbecue, at which some eight thousand guests partook of freshly slaughtered and roasted Texas cattle, the gift of Dr. Dean, and the Mexican luncheon tendered by the Dallas County Medical Society indicated a supervising skill on the part of the Committee of Arrangements which met with a universally grateful response. The lack of metropolitan entertainment facilities in a community the size of Dallas gave the Committee of Arrangements opportunity to provide unusual events for the delegates and visitors during the times when attendance was not required at the scientific or business sessions. The dinners, dances, receptions and the impromptu vaudeville held for large groups of visitors emphasized the social qualities of the annual session. The dispersion of the visitors after the scientific meetings, such as occurs in larger communities, was avoided to the interest of harmony and pleasant companionship for a far greater number than are ordinarily entertained in this manner at a medical convention.

The citizens of Dallas, the Committee of Arrangements. the press and the organizations of that city received the well merited thanks of the House of Delegates for the whole-hearted manner in which they took the American Medical Association into their hearts and made the Seventy-Seventh Annual Session not only the greatest medical meeting ever held in the South, but also one of the greatest ever held in this country.

HYPOGLYCEMIA AND CONVULSIONS

The manifestations of disease associated with an abnormally high content of sugar in the blood have long been the subject of serious experimental and clinical investigation, particularly in diabetes. If the development of scientific technic, notably micro-analysis of the blood, may be regarded as most largely responsible for the interest in hyperglycemia, it is probable that the study of the effects of insulin in the body has awakened an interest in the reverse condition of hypoglycemia. An unduly lowered level of circulating glucose in the blood is likely to be attended by characteristic symptoms often of menacing severity. Normal health thus seems to be concerned in no small measure with steering a path between the Scylla of hyperglycemia and the Charybdis of hypoglycemia.

In some respects the relationship between the blood sugar level and the appearance of symptoms is the same in various species.[1] Convulsive seizures occur when the hypoglycemic condition becomes extreme, and the pathogenesis of such conditions is indicated by the fact that administration of sugar has an antidotal effect. This is true whether the hypoglycemia is the result of overdosage with insulin or of extirpation of the liver and consequent exclusion of the glycogenic functions, as demonstrated by Mann and Magath.[2] It may still be debated whether the so-called hypoglycemic reactions can be explained entirely by the low content of blood sugar. Secondary associated detrimental factors may come into play; thus, one can imagine the accumulation of toxic substances rendered possible by disturbances in sugar metabolism. In any event, however, the menace of hypoglycemia, whatever its ultimate explanation may prove to be, is clinically a real one.

The history of medicine affords many illustrations of how the precise description of a pathologic entity has been followed by recognition of its previously unsuspected application to certain clinical conditions. Thus, recognition of the effects of experimental injury to the auriculoventricular conduction tissues of the heart was soon followed by new interpretations of various types of disturbed coordination of the heart beat. Similarly, the significance of hypoglycemia appears to be exemplified in certain somewhat obscure types of convulsions long known to occur in children at the outset of acute infections in particular. Josephs [3] of the Johns Hopkins University has furnished illustrations of the onset of convulsive attacks after short periods of fasting, often scarcely more than overnight abstinence from eating. Whereas in healthy children the sugar content of the blood may be little altered through such an alteration of the daily regimen so that the decrement does not exceed 15 mg. for each hundred cubic centimeters of blood, the febrile patients often exhibit hypoglycemia that reaches convulsive levels. Recurrent vomiting in children may have a similar provocation. Fever, though favoring the abnormal effects, is not, according to Josephs, necessary for the production of convulsions. The significance of the fever is probably twofold. In the first place, anorexia almost invariably accompanies the acute infections of childhood, and this anorexia may easily account for a period of fasting. The second effect of the fever is rather hypothetic. For some reason the children seem unable to mobilize their carbohydrate as rapidly as it is needed, with the result that the concentration of sugar in the blood falls. Fever, together with a short fast, has the effect of producing an attack, when simple fasting for the same length of time merely causes a lowering of the blood sugar. According to Josephs, furthermore, fever may either have an effect on the metabolism by diminishing mobilization of carbohydrate or, as seems quite probable, by increasing the rate at which the available carbohydrate is used up; or else it may merely render the child's nervous system more unstable, so that a lowered concentration of sugar in the blood, which under ordinary conditions causes no disturbance, would cause convulsions at the higher temperature. Ketosis is frequently an accompaniment of convulsions from fasting in acute infections, but the etiologic significance of the acetonemia remains doubtful.

BISMUTH COMPOUNDS IN ANTISYPHILITIC THERAPY

In addition to organic arsenicals and mercury compounds, preparations of bismuth have found a place in antisyphilitic therapy in the last five years. The usefulness of bismuth for this purpose seems to be assured, but there is pressing need of dependable evidence as to the sort of compounds of the element that are most likely to prove useful and as to the cases in which they should be applied. Arsenic and mercury are not uniformly or universally successful; there are cases known in practice as arsenic-fast or mercury-fast. To have an additional potent drug available for the attack in such resistant instances represents a distinct step toward progress. Not a few syphilologists already regard bismuth, properly used, as superior to mercury, though second to arsenicals, in the treatment of syphilis.[1] The spirocheticidal potency of bismuth seems to have been demonstrated in both the experimental and the clinical disease.[2] Current discussions center largely about the problems of the choice of therapeutic preparations, and to the mode of administration and their limitations and contraindications.

In a study sponsored by the Therapeutic Research Committee of the Council on Pharmacy and Chemistry of the American Medical Association, Cole, Farmer and Miskdjian have demonstrated anew that the use of suspensions of finely divided metallic bismuth is inadvisable, for such preparations tend to remain unabsorbed for long periods. This fact has been clearly established by roentgenographic observations, and at once warns against the danger of cumulative action of a toxic substance. The contention of French writers in particular, that insoluble bismuth salts must be injected biweekly in order to have a gradual, even absorption of the metal, is not borne out by these investigations. Insoluble salts of bismuth, such as the oleate, likewise failed to indicate worth-while absorption after injection deep into the lumbar muscles. The findings show that injections of metallic bismuth are dangerous and, if persisted in, will lead to cumulative absorption and possibly even to fatal results. The same is probably true, although to a lesser extent, of bismuth oleate. Bismuth salicylate likewise is not above this objection, and its use should be replaced by one of the more soluble bismuth salts—perhaps the potassium bismuth tartrate preparations. These salts, especially if injected intragluteally once a week, are probably not so likely to give rise to cumulative action. However, the patient should be observed closely, as even this salt is not above criticism so far as its absorption is concerned.

---

[1] Discussion on Cole, H. N.; Farmer, H. L., and Miskdjian, Hagope: Intramuscular *Absorption of Some Insoluble Bismuth Compounds* as Revealed by the Roentgen Ray, Arch. Dermat. & Syph. **13**: 227 (Feb.) 1926.

In contrast with arsenical therapy, the intravenous administration of bismuth compounds appears to be strictly contraindicated.[3] When suitable preparations are cautiously employed, undesirable complications, such as stomatitis or kidney involvement, can for the most part be avoided. Schamberg,[1] among many others, has voiced the belief that today bismuth is superior to mercury for the treatment of syphilis. In the animal experiments he has been able to destroy the spirochetes much more rapidly. Mercury and bismuth act the same on the kidneys, but in his opinion the bismuth is less toxic and more therapeutic. He thinks that it occupies a position between the organic arsenicals and mercury. It is Schamberg's custom to use intravenous injections of organic arsenicals and at the same time injections of bismuth. Cole, whose careful investigations lend weight to his views, frankly regards bismuth as a valuable drug in the treatment of syphilis, but he urges a conservative attitude until more evidence as to the precise effects of the drug is available. This caution is particularly advisable at a time when the urge to use all manner of secret commercial preparations persists. As Cole and his colleagues insist, granting that bismuth is a somewhat dangerous drug to employ in treating the human organism, surely some criteria should be evolved as to the safest, most potent and at the same time most practical preparation of this metal to be used in treating syphilis. Undeniable limitations have already been placed on record for certain types of bismuth preparations.

Current Comment

JABEZ NORTH JACKSON—PRESIDENT-ELECT

The election of Dr. Jabez North Jackson of Kansas City, Mo., to the position of President-Elect of the American Medical Association is the recognition of a favorite son of the great Southwest whose claims to the honor have been presented to the House of Delegates on previous occasions, indicating the continued high esteem in which he is held by his fellow physicians and their unwavering loyalty to him. Dr. Jackson was born in Labadie Mo., Oct 6, 1868, the son of John Wesley Jackson and Jennie Clark North. His father was, at the time of his death, Vice President of the American Medical Association. As chief surgeon of the Wabash Railroad, he had played a prominent part in opening up the Southwest and in its progress. After receiving his A.M. degree from Central College, Fayette, Mo., in 1890, Dr. Jackson attended the University Medical College in Kansas City, receiving his degree in medicine from that institution in 1891. He then went for postgraduate study to the New York Polyclinic, returning to take the position of demonstrator of anatomy in his alma mater, which he held until 1895. He succeeded to the professorship of anatomy, occupying that chair until 1898, when he became professor of surgical anatomy and adjunct professor of surgery. In 1899, Dr. Jackson married Virlea Wayland of Salisbury, Mo. His continuous development in surgical technic was recognized by his appointment to the chair of professor of principles and practice of surgery and clinical surgery in 1900, which position he occupied until 1911. Dr. Jackson became interested early in the work of the National Guard, serving as assistant surgeon, and later as surgeon, of the Third Regiment of the Missouri National Guard from 1893 to 1898, and as major and brigade surgeon of the United States Volunteers in charge of the Second Division Hospital of the Second Army Corps during the Spanish-American War. From the beginning of his medical career, Dr. Jackson has been interested in the affairs of medical organization. He was president of the Medical Association of the

Jabez North Jackson, M.D.
President Elect of the American Medical Association

Southwest in 1898, of the Kansas City Academy of Medicine in 1900, of the Missouri State Medical Association in 1904, and of the Western Surgical Society in 1913. He also has been prominent as a member of the Missouri Valley Medical Society and of the Pan-American Medical Congress. His name is associated with many discoveries in surgical technic, and particularly with the elucidation of "Jackson's membrane" and associated surgical conditions.

"GLOBOID BODIES"

The demonstration of the occurrence of so-called filtrable or ultramicroscopic viruses, microbic agents responsible for the transmission of disease but not visible through the ordinary modes of microscopic examination, has paved the way for consideration of all sorts of intermediate types. Analogous to the existence of nonliving matter in states of aggregation varying from substances in true solution to "colloidal" solutions or even more or less homogeneous suspensions, it has become easier to conceive of animate forms capable of reproduction and existing in an almost equally varied range of aggregate sizes. In 1913, Flexner and Noguchi actually applied the expression "globoid bodies" to minute spherical forms that they believed were cultivated from the filtrable virus of poliomyelitis. Comparable statements have been made in relation to other diseases; recently, for example, Duval and Harris[1] have described a "globoid micro-organism" in cultures of the blood from dengue fever. The "bodies" in question measure a small fraction of a micron in diameter and require special technic for their visual demonstration. It has also been asserted within the last decade that certain bacteria, notably aerobes, may develop anaerobically as minute forms. On the other hand, bacteriologic investigators have maintained that all such minute structures are artefacts, such as sphere-crystals. Sometimes they remain dispersed in a complex colloidal system represented by certain mediums, only to undergo a crystallization or separation in concrete form under the influence of inoculation. It is possible, indeed, to imitate microbic growth by "inoculating" supersaturated solutions with a few crystals. Interest in these phenomena was popularly accentuated through the widely heralded studies of Barnard and Gye in England on the alleged virus of cancer. The "organisms" dealt with by them were visualized through special ultramicroscopic devices. Harris[2] of the Department of Pathology at Tulane University in New Orleans has lately defended the existence of truly animate entities in the form of "globoid bodies." He states that the inoculation into guinea-pigs of cultures containing these globoidal micro-organisms, obtained from the blood of patients infected with dengue fever, reproduced the febrile and leukocytic reactions present in this disease. Harris admits that there exist certain artefacts which resemble the colonization observed for globoid bodies, but these are inanimate structures and can be differentiated from the living micro-organismal forms. Hence Harris believes that globoid bodies are minute living micro-organisms of a much smaller size than the usual small recognized forms. They have a definite structure consistent with true micro-organisms. They can be grown in cultures which, when inoculated into the experimental animal, reproduce the disease from which they were primarily isolated.

NEW YORK'S NEW MEDICAL PRACTICE ACT

The House of Delegates, at Dallas, unanimously adopted a resolution thanking Governor Smith of New York for his interest in the protection of the people against quackery and urging him to approve the medical practice act just passed by the legislature. The act, which has had the support of the Medical Society of the State of New York, requires every physician to register annually and to pay a fee of two dollars, on or before January 1. A list of the physicians so registered is to be sent to each registrant in March, with a request that he report every known practitioner of medicine whose name is not listed. Registration fees are available for the enforcement of the act. The Board of Regents, the licensing body, is authorized to appoint inspectors to enforce the law throughout the state. Prosecutions are to be by or under the direction of the attorney general, and not by local district attorneys as at present. A "committee on grievances" is to be appointed by the Board of Regents, consisting of seven licensed physicians appointed from lists submitted by the Medical Society of the State of New York, the New York Homeopathic Society and the New York State Osteopathic Society, and three appointed independent of such nominations. This grievance committee may hear all charges against licensed physicians looking toward the revocation of their licenses. It merely reports its findings and recommendations, however, to the Board of Regents. The board may accept or modify the findings and recommendations of the committee, and in any case the defendant may appeal to the courts. The grievance committee may act as a board of arbitration in controversies between two or more physicians, or between a physician or physicians and any other person, if the parties so request. The new law, correcting a condition disclosed by a recent decision of the New York Court of Appeals, provides that in an action for damages for personal injuries or death against an unlicensed person, arising out of an act or acts constituting the practice of medicine, the fact that such person was practicing without license shall be deemed prima facie evidence of negligence on his part. An alien seeking a license to practice medicine must have declared his intention of becoming a citizen, and if he fails within six years from the date of such declaration to furnish evidence of naturalization, his license terminates. In view of the time and energy that have been devoted to the drafting and enactment of this law, the profession will look forward with interest to the results accomplished by it. The physicians of New York are apparently almost unanimous in their belief that, when effective, it will do much to protect the public against medical vagaries.

PROCEEDINGS OF THE DALLAS SESSION

MINUTES OF THE SEVENTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT DALLAS, TEXAS, APRIL 19-23, 1926

(Concluded from page 1297)

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, April 20

The House of Delegates was called to order at 9:30 a. m. by the Speaker, Dr. Fred C. Warnshuis.

Supplementary Report of the Committee on Credentials

A supplementary report of the Committee on Credentials was submitted by the Chairman, Dr. J. D. Brook, Michigan, who reported that there had been filed with the committee credentials totaling 141.

There being no objections, the supplementary report of the Committee on Credentials was received.

Report of Reference Committee on Sections and Section Work

Dr. Tom B. Throckmorton, Section on Nervous and Mental Diseases, read the report of the Committee on Sections and Section Work:

1. The Reference Committee on Sections and Section work begs to report that it has carefully read and discussed the report of the Council on Scientific Assembly as printed on pages 121-123, inclusive, of the Official Hand Book, and presented in substance by the Chairman, Dr. J. Shelton Horsley, and recommends that the report of the Council be approved in its entirety.

2. The committee is in full accord with the traditional custom of the Council in its method of assigning the hours of the sections so as to alternate the time of section meetings from year to year.

3. The Reference Committee on Sections and Section work feels that the Council on Scientific Assembly has given an attentive ear to requests made for the creation of a new section on physical therapy and that the Council has acted most wisely and judiciously in unanimously adopting the policy of nonrecommendation of such request until it has been amply shown that the need for a separate section on physical therapy actually exists.

4. The committee feels that the Council on Scientific Assembly was amply justified in not recommending the reestablishment of a section on stomatology, and that the suggestion of the Council that papers dealing with stomatologic subjects be assigned for presentation in the Section on Miscellaneous Topics was fair and was actuated for the best interests of the Association.

Respectfully submitted.

J. L. Rothrock,
W. P. Eagleton,
W. G. Ricker,
Tom B. Throckmorton,
Chairman.

Dr. Tom B. Throckmorton, Section on Nervous and Mental Diseases, moved that the report be adopted.

The motion was seconded by Dr. Albert Soiland, California, and carried.

Report of Reference Committee on Medical Education

Dr. F. B. Lund, Massachusetts, read the report of the Reference Committee on Medical Education:

The report of the Council on Medical Education and Hospitals records the figures of the Council's activities during the last year. It is a record of industrious work in the line of its previous reports and of enormous responsibilities.

These activities in general the committee approves.

The improvement in the facilities for graduate instruction as a direct result of its labors is also of great value and importance.

The inspection of hospitals has resulted in perfecting facilities for the intern training to 4,683 graduates, and in the corresponding improvement of and advantage to the hospitals themselves.

The value of the elimination of hospitals where unethical practices are carried on is self-evident.

The list of the colleges of arts and sciences which are adequate to provide premedical training is also an extension of the Council's work which is of great value and importance in the guidance of those intending to make medicine a career.

The list of clinical laboratories ought to prove of great value to practitioners by enabling them to get work done that is of no value unless it is done well, but when well done and accurately done is of the greatest value.

But, owing to the immense extent of the work involved, in the opinion of the committee, it is important to secure the cooperation of every state medical society and its component societies in order to compile a complete and adequate list of clinical laboratories.

In regard to the facilities for the enrolment of medical students, a serious question is raised in the minds of your committee as to whether properly qualified students are now able to secure enrolment in medical schools, and we are glad to note that an investigation is now being made with this as its object.

Age at graduation ought to be reduced, and the committee recommends to the Council on Medical Education and Hospitals that further efforts be made to reduce the average age at graduation. In this connection the committee recommends that the resolution introduced by Dr. Southgate Leigh, Virginia, be adopted; namely, that the House of Delegates request the Council to consider the feasibility of allowing medical students credit for courses taken during the summer months, in a manner similar to the plan followed in the academic departments. The Council is further requested to confer with the various medical schools, asking their cooperation in this important movement.

In regard to nursing education, your committee regards with great approval the resolution introduced by Dr. E. Eliot Harris of New York, and recommends its adoption and enforcement.

Resolved, That there is a great need throughout the country for a basic trained nurse, and that all pupil or student nurses shall receive basic training in training schools connected with hospitals giving courses of two years. The curriculum should be thoroughly revised so as to provide bedside instruction, class room lectures and demonstrations and, above all, the teaching of the art of nursing by precept and example so as properly to fit the pupils or students for their work as nurses in the hospitals and in the homes

Graduates, after passing the state examination, should be registered as trained or, if preferred, registered nurses. Such trained or registered nurses may become public health or other specially designated nurses after being properly admitted to postgraduate schools for nurses and passing the required examination

Resolved, That the Board of Trustees appoint a committee on nurses and nursing education to investigate and report to the next House of Delegates the results of its investigation and constructive thought on the nursing question and especially on the subject of increasing the number of bedside nurses throughout the several states; the Committee on Nurses can be empowered to confer with the National Nurses Association, hospitals and other committees having similar objects.

In the report of the Council, on page 116, in the fine print, the committee feels that the phrase "under the orders of the physician or the regular staff of the hospital" should be changed to "of a reputable physician practicing in the hospital." This change is recommended in order to provide for reputable hospitals which admit private patients under the care of physicians not on the regular staff, the so-called "open hospital."

J. N. Hunsberger,
W. A. Pusey,
B. R. McClellan,
F. B. Lund,
Chairman.

Dr F. B Lund, Massachusetts, moved that the report be adopted The motion was seconded by Dr. I. A. Abt, Section on Diseases of Children, and carried.

Report of Reference Committee on Legislation and Public Relations

CONTRACT PRACTICE

Dr H. M Brown, Wisconsin, stated that the Committee on Legislation and Public Relations had four bills brought before it, one by Dr A. D. Dunn, Nebraska. The report on the resolution is that the committee recognizes the need of action and recommends that the Board of Trustees be requested to furnish the Judicial Council such assistance as may be necessary for the proper prosecution of the work and recommends the passage of the resolution.

Dr H M. Brown, Wisconsin, moved that the resolution be adopted The motion was seconded by Dr. W. D. James, North Carolina, and carried.

MEDICAL LEGISLATION

The next item of the report of the committee referred to a resolution introduced by Dr. Southgate Leigh, Virginia:

Whereas, The strength of the medical profession in the field of legislation is lessened by lack of uniformity in policies and methods; and

Whereas, Such uniformity can be promoted and established only through cooperation among the several state associations whereby each will have the benefit of the knowledge and experience of all others; and

Whereas, Such cooperation can be best established through the Board of Trustees, acting through the Bureau of Legal Medicine and Legislation, be it

Resolved, That every state association be urged to cooperate to the fullest possible extent with the Board of Trustees in all matters of legislation, state and national, and be it further

Resolved, That the Board of Trustees be requested to extend to every state association all such assistance as may be possible in defining and carrying into effect its legislative policies, and in promoting uniformity in them

Dr H. M Brown, Wisconsin, moved that the resolution be adopted The motion was seconded by Dr. A. D. Dunn, Nebraska, and carried.

EXPERT OPINION EVIDENCE

Dr. H. M. Brown, Wisconsin, read the report of the Committee on Expert Opinion Evidence and moved that it be adopted The motion was seconded by Dr. A. J. Bedell, New York.

Dr. J N. Henry, Pennsylvania, suggested an amendment on the ground that there was no use passing a resolution giving moral support to a vague resolution of this sort. He stated that a letter said that the bill was approved by the American Institute of Criminal Law and Criminology and by the American Bar Association, the Committee on Jurisprudence and Law Reform of the American Bar Association. The amendment suggested was as follows:

And further be it

Resolved, That the House of Delegates endorses certain principles approved by the American Bar Association and by the American Institute of Criminal Law and Criminology, that in civil and criminal cases where the issue of insanity is raised, the court may appoint expert medical witnesses who shall be paid out of public funds and who may furnish a written report.

Dr. Henry stated that this bill was enacted substantially in Wisconsin, and the general provisions of the first section were enacted in New York.

Dr. A. E Bulson, Jr., Indiana, moved that the amendment be incorporated with the reference committee's report. The motion was seconded.

Dr. H. W. Orr, Section on Orthopedic Surgery, suggested that, following the word "insanity," where the question of insanity was raised, there be added the words "or compensation for industrial injury."

Dr. J. N. Henry, Pennsylvania, did not accept this amendment

Dr G E. Follansbee, Ohio, in discussing the adoption of the amendment, said that if the House was of the opinion that those details should be included in the report of the reference committee, he believed that the resolution as originally presented more fully covered the thing than the amendment that had been introduced. The matter of the expert opinion witness in matters of insanity was important, but no more important in many of our large cities than the matter of the expert opinion the witness establishes where insanity is not introduced. It was quite important that we should have unbiased witnesses appointed by the court. Insanity was not involved in civil cases. If this amendment should be adopted, it covered only a half of the abuse of expert opinion evidence. If there was any way to refer the report back to the reference committee with instructions how to rewrite it including civil cases as well as criminal cases, this was the action that ought to be taken.

A substitute motion, that the whole thing be referred back to the committee with instructions to report at some later meeting was seconded by Dr. Bulson, Indiana, and adopted.

Dr. H. M. Brown, Wisconsin, moved the adoption of the report as a whole, eliminating the part of the report that had been referred back to the committee. The motion was seconded and carried.

Report of Reference Committee on Hygiene and Public Health

Dr. A. T. McCormack, Kentucky, read the report of the Reference Committee on Hygiene and Public Health:

We beg leave to submit the following report in regard to resolutions referred to this committee.

We endorse that part of the report of the Board of Trustees in regard to the sale and distribution of zinc stearate as appears on page 80 of the Hand Book, and recommend its adoption

We endorse the report of the Advisory Committee on Trachoma Among the Indians, as submitted by the special committee on this subject, and recommend its adoption.

We endorse the report of the Special Committee on Narcotic Drugs and recommend its adoption.

We recommend that another conference on periodic health examination be held next year at the same time the conference of state secretaries takes place.

We recommend the adoption of the following resolution in regard to the use of the title "Doctor":

Whereas, The title "Doctor" in a medical sense has from the earliest times been associated with the treatment of human ailments; and

Whereas, Most of the states now grant licenses to treat the sick to persons of limited educational qualifications, such persons not being graduates of reputable medical schools; and

Whereas, The use of the title "Doctor" by persons of inferior educational qualifications constantly misleads the public, resulting in much unnecessary suffering and many untimely deaths; therefore, be it

Resolved, That it is the sense of the American Medical Association that, for the protection of the public, the title "Doctor" in a medical sense be restricted to doctors of medicine and doctors of dental surgery

A. T. McCormack, Chairman,
S. W. Welch,
Charles E. Humiston,
L. H. McKinnie,
Charles E. Mongan.

Dr. A. T. McCormack, Kentucky, moved the adoption of the report of the committee as a whole. The motion was seconded by Dr. Soiland, California, and carried.

Report of Reference Committee on Amendments to Constitution and By-Laws

MEETING IN CANADA

Dr. J. W. Van Derslice, Illinois, Chairman, reported that the Reference Committee on Amendments to Constitution and By-Laws recommended that the amendment offered by Dr. Keiper amending Article 10 of the Constitution be not approved.

Dr. J. W. Van Derslice, Illinois, moved that the report be adopted. The motion was seconded by Dr. Moll, Michigan, and carried.

RECOGNITION OF LAY SECRETARIES

The committee recommended that the amendment offered by Dr. Hunt, New York, providing for the recognition of lay secretaries of constituent state associations be not approved. While recognizing their excellent work and attendance at the meetings, yet it is considered not feasible to give them official representation in the sessions.

Dr. J. W. Van Derslice, Illinois, moved the adoption of this portion of the report of the committee. Seconded and carried.

APPOINTMENT OF EMERGENCY OFFICERS

The committee recommended and approved that there be added to the words "appoint emergency committees" the following: "In the case of a vacancy by death or otherwise in the office of President-Elect, the Secretary or Treasurer, the Board of Trustees shall fill the vacancy for the unexpired term."

Dr. J. W. Van Derslice, Illinois, moved that addition of this to the By-Laws, authorizing the Board of Trustees to fill the office in case of vacancy of Secretary, President-Elect, and Treasurer. The motion was seconded by Dr. C. J. Whalen, Illinois. After discussion by Dr. E. B. Heckel, Board of Trustees, and Dr. A. H. Bunce, Georgia, the motion to adopt this part of the report was lost.

PLACE OF ANNUAL MEETING

The committee suggested a change in Chapter 6, Section 1, under the duties of the Board of Trustees, "The Board of Trustees shall select the place of meeting for the annual meeting of the American Medical Association." This will come up for voting at the next regular session.

This notice of amendment to the Constitution and By-Laws will lay over until next year.

Dr. J. W. Van Derslice, Illinois, moved the adoption of the report as amended. Seconded by Dr. Bert L. Eiker, Iowa, and carried.

Delegates to Dedication of Murphy Memorial

Dr. E. B. Heckel, Board of Trustees, reported on the appointing of delegates to represent the Association at the dedication of the Murphy Memorial. The Board approves of this project and suggests that the Speaker of the House appoint two delegates to represent the Association at the dedication of the Murphy Memorial, June 10-11.

Dr. Albert Soiland, California, moved that the House adopt the recommendation of the Board of Trustees that the Speaker appoint two delegates from this body to represent the American Medical Association at the dedication of the Murphy Memorial. Seconded and carried.

COSMETICS

The Secretary read the supplemental report with reference to cosmetics.

The House of Delegates at Chicago, 1924, adopted a resolution authorizing the fostering of legislation to place cosmetics under the restrictions of the food and drug laws, to require the names of all poisonous ingredients to be placed on labels, and to prohibit the use of the most harmful ingredients in cosmetics. The resolution adopted provided further for the promotion of legislation to prohibit the use of paraphenylendiamine as a dye for hair and fur. The Bureau of Legal Medicine and Legislation undertook to study the evidence to support a plea for the enactment of such legislation and to enable the bureau to draft the legislation proposed. At the request of the bureau, the Board of Trustees appointed a technical committee, to cooperate.

In 1925, at Atlantic City, the House of Delegates reiterated its views in the following resolution:

WHEREAS, There has been an enormous increase in the use of cosmetics; and

WHEREAS, Many of these cosmetics contain chemicals irritating and dangerous to the human organism; and

WHEREAS, A special committee of the American Medical Association is now in existence, appointed to investigate these problems; be it

Resolved, That the Trustees of the American Medical Association be urged to finance and push the work of this special committee.

Work under these resolutions continues. Questionnaires have been submitted to approximately 450 dermatologists seeking reports of injuries due to the use of cosmetics, hair dyes and dyed furs, and the replies are being tabulated. The evidence at hand, however, is insufficient to form the basis of any recommendation.

This was referred to the Reference Committee on Hygiene and Public Health.

Supplemental Report on Medical Education

Dr. F. B. Lund, Massachusetts, read the following supplemental report of the Reference Committee on Medical Education:

On page 117, the last three lines reading "A committee on the public responsibilities of the medical profession be created consisting of one member for each of the councils and bureaus and at least three additional serving for five year term," the committee recommends that for the phrase beginning with the word "consisting" the following be substituted:

"Consisting of five members appointed in the usual manner, namely: Nominated by the President and elected by the House of Delegates."

J. NEWTON HUNSBERGER.
W. A. PUSEY.
BEN R. MCCLELLAN.
F. B. LUND, Chairman.

Dr. F. B. Lund, Massachusetts, moved that the report be adopted. Seconded by Dr. B. R. McClellan, Ohio, and carried.

Address by Hubert Work

The Speaker presented the first Speaker of the House of Delegates, Hon. Hubert Work, Washington, D. C., Secretary of the Interior, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates:

It affords me the greatest pleasure, I assure you, to stand here before you again if only for a moment in this semidetached position. I have a memory of more than twenty years' association with this House of Delegates. For twenty years I held office of some sort or other in this House. I thought then, and I think now, that no body of men selected from the United States for any purpose or from any locality has quite the acumen that the House of Delegates of the American Medical Association has.

Speaking of it the other day to a man with whom I was traveling, he said, "It is perhaps like Congress."

I said, "Yes, and no. These men are all educated and they are all mind readers and no man can stand before the House of Delegates for a series of years, as your Speaker has, and stand up except that they read his mind before he frames it in words."

I would like to say a word perhaps from a detached position about the American Medical Association and its present status as I see it now. We all know that a monument is a structure erected in a community perhaps that stands away from any other similar structure made from the same materials in that vicinity. It is to commemorate some person or some thing. The American Medical Association, when George Simmons left it, who was the architect of this monument to American medicine, had turned over to it a monument in the shape of a magnificent building in Chicago, and the splendid organization that he matured and left was merged into the new organization. It was quite a revolution. Yet this change was accomplished without any disturbance and of course with great improvement to the medical organization.

I see before me many men here who mixed the mortar and who carried the hod and who laid the stone to erect this great monument of the American Medical Association to American medicine. Each of us perhaps has borne his humble part in it, but each part was necessary to the consummation of the whole. I for one look back with the greatest pride on any small part I may have had in erecting this monument to American medicine and to the medical profession of the United States.

Gentlemen, I thank you. (Applause.)

Cablegram to Dr. Simmons

Dr. A. T. McCormack, Kentucky, moved that the Speaker and the Secretary be instructed to send a cablegram to Dr. Simmons expressing the love, affection and gratitude of this House. Seconded by Dr. O. S. Wightman, New York, and carried unanimously.

Report of Reference Committee on Report of Board of Trustees and Secretary

Dr. E. Eliot Harris, New York, presented a partial report on the Board of Trustees and moved that it be considered in a Committee of the Whole in executive session.

Dr. Holman Taylor, Texas, read a partial report by the Reference Committee on the Board of Trustees.

Dr. E. Eliot Harris, New York, moved that the portion of the report on the Board of Trustees be referred to a Committee of the Whole in executive session. Seconded by Dr. E. J. Goodwin, Missouri, and carried.

The Speaker called as Chairman of the Committee of the Whole the Vice Speaker of the House, Dr. Rock Sleyster, Wisconsin.

The House of Delegates went into a session of the Committee of the Whole.

The House of Delegates reconvened at 12 o'clock, the Speaker, Dr Fred C. Warnshuis, in the chair.

Dr. Rock Sleyster, Wisconsin, chairman, reported that the Committee of the Whole had for consideration the report of the Reference Committee on reports of the Board of Trustees and Secretary. The Committee of the Whole accepted the reports as reported by this committee and recommended its adoption by the House of Delegates, as follows:

We have conducted an extended hearing on several matters referred to our committee and beg at this time to submit a partial report, covering those matters referred to in the hearing and on which the committee has been able to make decision.

REPORT OF BOARD OF TRUSTEES

On pages 6 and 7 of the Hand Book will be found a discussion of the National Prohibition Act, and the action of the Board of Trustees, pursuant to a resolution on the subject adopted by this House in 1925. On page 100 of the Hand Book will be found the report of the committee appointed by the Board of Trustees at the instance of the House of Delegates and under the resolutions already referred to. This report sets out certain regulations intended to support the national prohibition authorities and protect the medical profession, in the instance the quantitative limitations features of the National Prohibition Act, as amended, be declared unconstitutional by the U. S. Supreme Court:

Our committee recommends that the committee created by the above mentioned resolution of the House of Delegates and appointed by the Board of Trustees, to cooperate with the Commissioner of Internal Revenue and the Secretary of the Treasury, be continued as at present constituted in the matter of personnel, with such additional members as the Board of Trustees may determine, and that the said committee report, through the Board of Trustees, to the next session of the House of Delegates.

On page 82 of the Hand Book, the subject of the Gorgas Memorial is discussed. The Board of Trustees declined to agree to a certain degree of participation in the project in hand, reciting the reasons for so declining. Our committee feels that the medical profession warmly approves well conducted and properly controlled efforts to educate the public on health matters, but feels that it might be a dangerous expedient to lend its influence to the creation of an enormously financed foundation, under federal charter, for these purposes, without adequate control by this body. It will be understood that the present plans contemplate control by a mixed lay and medical board, on which the Association has less than 10 per cent representation, and that the accomplishments of the foundation thus created depend almost entirely on the active cooperation of the medical profession. Your committee recommends that the Board of Trustees stand ready at all times to consider cooperative proposals looking to the perfection of feasible, safe and effective plans of cooperation, reporting from time to time to the House of Delegates.

On page 84 of the Hand Book appears a discussion of the lack of uniformity in reporting deaths in the puerperal state, having reference to a resolution introduced by Dr. Mongan, Massachusetts, in 1924. There appears this language:

"Methods of securing and of editing death returns in England and Wales and those found in use elsewhere were defined in the statement of the Bureau of Census, in which it was pointed out that to adopt the English methods simply because it produces a lower rate than some other methods would be unsound practice."

Our committee feels that the Bureau of Census has missed the point of Dr. Mongan's resolution, which was not to show a lower death rate but rather to separate deaths *associated* with pregnancy from those *directly due to* pregnancy, that there may be a fair basis of comparison in this regard with England and Wales.

On page 86 of the Hand Book, the subject of a full-time representative in Washington is discussed. The Board of Trustees has declined to appoint such a representative in Washington on a full-time basis, as requested by the House of Delegates at Atlantic City last year, in the belief that the House of Delegates did not understand at the time the aforesaid action was taken that the Association had connections in Washington that were believed by the Trustees to be adequate. A majority of the reference committee of last year which had recommended a full-time representative in Washington appeared before this committee and asked that the matter be considered by the House of Delegates in Executive session, as a Committee of the Whole, and it is so recommended.

Respectfully Submitted.

E. Eliot Harris, Chairman.
C. J. Whalen.
Holman Taylor.
E. J. Goodwin.
A. H. Bunce.

Dr. Rock Sleyster, Wisconsin, moved that the report be adopted. Seconded by Dr. Thomas C. Chalmers, New York.

Dr. Rock Sleyster, Wisconsin, added to the report that the Committee of the Whole would be in favor of advising the House of Delegates that the Board of Trustees be requested to provide a representative in Washington during the legislative sessions.

The report of the Committee of the Whole reporting on the report of the Reference Committee on Board of Trustees and Secretary was adopted.

Report of the Reference Committee on Miscellaneous Business

Dr. Bertram L. Bryant, Maine, read the report of the Reference Committee on Miscellaneous Business:

The Reference Committee on Miscellaneous Business thinks the resolution introduced by Dr. D. E. Sullivan, New Hampshire, asking that a survey be made of the physical condition and financial status of those of our members who are unable to earn their support by the practice of their profession, with the objective of establishing and maintaining a home for their care, is well worthy of favorable consideration by our Board of Trustees, and recommends that a committee be appointed by the President empowered to act, in carrying out the intent of this resolution.

B. L. Bryant.
C. O'Donovan.
E. D. Ebright.
M. L. Stevens.
E. P. North.

Dr. Bertram L. Bryant, Maine, moved that the report be adopted. Seconded by Dr. A. E. Bulson, Jr., Indiana, and carried.

The Secretary read a communication from the Secretary of the Canadian Medical Association inviting the American Medical Association to send a delegate to its annual session. The invitation was referred to the Board of Trustees.

A letter and other communications from Dr. Robert V. Day, a member of the House of Delegates, from California, having to do with the passage by Congress of a bill to secure the appointment of Dr. Derbyshire as a surgeon in the regular corps of the United States Public Health Service, so that he may be retired with the advantage of the pay granted to officers of that advantage, was laid on the table.

The Secretary read a letter from the general secretary of the National Catholic Welfare Conference asking the American Medical Association to protest against pending legislation authorizing the dissemination through the mails of information concerning contraception. The matter was referred to the Board of Trustees.

NEW BUSINESS

Bill Coordinating Public Health Activities

Dr. S. W. Welch, Alabama, introduced the following resolution:

Resolved, That the House of Delegates of the American Medical Association endorse the principles embodied in H. R. 10125, a bill to provide for the coordination of the public health activities of the government and for other purposes.

This was referred to the Reference Committee on Legislation and Public Relations.

Affiliate Fellowship

Dr. E. J. Goodwin, Missouri, introduced the following amendment to Section 5, Chapter XI, of the By-Laws, merely giving affiliate fellows the subscription to The Journal without cost to them.

Amend Section 5 of Chapter XI of the By-Laws as follows: Strike out the word "not" at the end of line 13 and the words "except by" in line 15, and substitute the word "without" for the words "except by," so that the section when amended shall read as follows:

Sec. 5. Affiliate Fellows.—A Fellow who has been a Fellow for a continuous term of fifteen (15) years, who is not less than sixty-five (65) years of age, and who is an honorary member of his component society and of his constituent association, or is connected with these organizations in an equivalent manner whereby he is relieved from the payment of dues or fees, on request of his constituent association may be made an Affiliate Fellow by a majority vote of the House of Delegates of this Association. Affiliate Fellows shall be privileged to participate in the Scientific Assembly of the Association; they shall not be required to pay Fellowship dues and shall receive The Journal of the American Medical Association without personal subscription. Affiliate Fellowship shall be conditioned on such an Affiliate Fellow continuing the relationship with his constituent association herein defined.

This was referred to the Reference Committee on Constitution and By-Laws.

Address of Col. Gilbert E. Seaman
of the Veterans' Bureau

Dr. H. M. Brown, Wisconsin, asked the privilege of the floor for Colonel Seaman of the Veterans' Bureau.

Dr. A. E. Bulson, Jr., Indiana, moved that the floor be granted to Colonel Seaman. Seconded by Dr. J. Norman Henry, Pennsylvania, and carried.

Col. Gilbert E. Seaman, Veterans' Bureau, spoke as follows:

Mr. Speaker, and Members of the House of Delegates:

I come representing the director of the United States Veterans' Bureau and the medical director, and bring to you and to the American Medical Association the greetings of General Hines, the director, and Dr. Crossman, the medical director, for the purpose of presenting a few thoughts in connection with the problems of the medical service of the United States Veterans' Bureau.

The United States Veterans' Bureau is without doubt one of the greatest relief organizations in the world. The administration of the bureau presents problems and difficulties, solution of which calls for the highest class of service.

During the formative period, the bureau's work has been subject to considerable criticisms, and no doubt some of this criticism was warranted, but it is believed that the work is now on a sound basis and is going forward in accordance with the desires of the people and the government and to the satisfaction and relief of ex-service men. In any case, the administration of the present director of the Veterans' Bureau has received the general approval of the public and the veteran. Economies have been effected and facilities for the care of the ex-service man have been much improved and enlarged in order to meet the requirements of the Veterans' Bureau law. The Director of the U. S. Veterans' Bureau welcomes constructive criticism. He has perhaps the most difficult problem that could fall to the lot of any servant of the government. It is recognized that the problem is in a very large measure a medical problem.

The medical service of the U. S. Veterans' Bureau has the largest number of hospitals, dispensaries, and by far the largest number of patients under one organization in the United States, if not in the world. The medical director and the medical service as a whole recognize the fact that this service cannot be rendered in accordance with the desires of the people, the Congress, and the interests of the veteran without the best cooperation and the generous assistance of the medical profession of America, particularly the medical profession as represented by the American Medical Association. It is for that reason that each succeeding year some effort has been made to interest the American Medical Association, and to gain your confidence and support.

The American Medical Association has always been noted for its cordial support of the various medical arms of the government in the solution of their problems. This association deserves a large measure of credit for the success of the medical department of the Army, the Navy, and the Public Health Service; and now, this latest medical arm of the government comes to you with its problems, endeavors to state them, asks for your careful consideration, for your expert advice, and for your cooperation in the solution of their difficulties.

The medical service of the Veterans' Bureau does not make the law as it applies to the medical care and relief of veterans; that is the function of Congress representing the government and the people. The function of the medical service is to follow the provisions of the law and render to the disabled ex-service man such hospitalization and other medical care and attention as is provided by the government. It has been said that the medical service has the largest medical problem on its hands of any organization in America. It may also be said that it has the largest medical opportunity and it may reasonably be expected to take advantage of that opportunity in advancing the science and art of medicine with a primary purpose of giving the disabled ex-service man or woman the advantages of the most advanced information available to the medical profession.

There were approximately five million men and women who served in the war. Of this number a certain proportion suffered in health, or will suffer by reason of their service. The Veterans' Bureau conducts fifty hospitals and more than one hundred dispensaries. In these hospitals during the past year there have been hospitalized approximately 77,000 patients. At the end of the last fiscal year there were in hospitals approximately 27,000 patients. Of this number 83 per cent were suffering from service connected disabilities, while 17 per cent were veterans of all wars or military movements since 1897 suffering from disabilities which may or may not have been connected with military service, some having applied but their service connection not yet determined. Many of these were veterans of the Spanish American War, the Philippine insurrection, the Boxer rebellion, and later military operations, some of whom had grown old, many of them drawing small pensions, and all of them suffering from some disability, compensable or otherwise. The World War Veterans' Act provides, it is true, for the care of veterans under certain circumstances regardless of the origin of their disability, but only when hospital facilities in Veterans' Bureau hospitals are available, and preference is given to those who are financially unable to adequately care for themselves. It will therefore be seen that this very generous, many people think too generous, and some people think unwarranted provision of the law, does not apply to a very large percentage of the total number in hospitals. The extension of Veterans' Bureau hospital facilities for the care of nonservice connected disabilities of ex-soldiers is not contemplated. It is desired to point out, however, that the law is not made by either the director or the medical service, but by the Congress representing the people, and the problem of the medical service is to efficiently apply the law and render the relief afforded under its provision.

In order to better render this relief, and do so in accordance with the generally accepted and best available medical thought and opinion, the Veterans' Bureau called to its assistance, in March, 1924, the organization known as the Medical Council, consisting of physicians and experts of national prominence representing the several specialties in medicine. This council holds two or more meetings each year at the call of the director and the medical director, and at the end of each session makes such recommendations as they see fit for the betterment of the medical service to be rendered to the disabled veteran. The head of that council is your distinguished ex-president, Dr. Ray Lyman Wilbur, and it is made up entirely of men of outstanding eminence in the medical profession, practically all of whom are leaders in the American Medical Association. As a result of the activities of the Medical Council, a medical research section was recently established in the medical service of the Veterans' Bureau and has already done excellent work in the standardization of procedure in the field of laboratory and clinical research. There have also been established diagnostic centers for the exhaustive study of cases presenting difficulties of diagnosis, or which are the subject of medical controversy. These centers afford the most modern equipment with attending staffs of outstanding qualifications, and have as their purpose, on the one hand, making a diagnosis on which a proper and compensable rating may be made, and, on the other hand, the elimination of unnecessary hospitalization and other expense. The hospitals of the United States Veterans' Bureau have been the subject of careful study by the American College of Surgeons, and all but two or three have been accepted as meeting the standard requirements of hospitals as laid down by the American College of Surgeons. The medical service has also provided for postgraduate instruction to its medical officers, particularly in the fields of tuberculosis and neuropsychiatry, which, largely on account of the provisions of the law, constitute a very important part, if not a major part of the entire medical problem.

Attention is called to the fact that the 27,000 patients in hospitals at the end of the last fiscal year represent slightly more than one half of one per cent of those who were in the military service during the war, not an unreasonably large number surely. The service men are not all in hospitals, only one out of 200 who served. Of this 27,000 cases at least 20,000 were cases of tuberculosis and neuropsychiatric disease, many of which were hospitalized by reason of the presumptive clauses of the law.

In the earlier history of the Veterans' Bureau, by reason of the attitude of the people and the ex-service men, the emphasis was laid too largely on compensation; but with a better understanding of the problem on the part of all concerned, including the service man, the emphasis is now being laid on cure and rehabilitation, rather than compensation, and for the future this will be not only the slogan but the true guiding principle of the medical service of the U. S. Veterans' Bureau.

It is believed that a provision of the law granting hospitalization to those without compensable disabilities, and particularly those in needy circumstances, has some merit at least from the standpoint of public policy. It is not always an easy matter to convince the people in any community, or the ex-service man, that military service had nothing to do with an existing disability, and also that a man who has rendered military service is not in some measure at least entitled to the consideration of his government. It is believed that good public policy dictates that there be generous recognition of the sacrifices often involved in military service in time of war, and no doubt that has been the dominating note in the policy of the United States toward the veterans of all wars. It is true that the application of this policy at times involves mistakes in individaul instances and perhaps expense not fully warranted in the individual case, but is this not true of all philanthropic effort? Is it not true that the many state hospitals, city hospitals, private philanthropic hospitals, and public and private clinics and dispensaries render service often to those who not only could afford to do so, but would be benefited by carrying their own burdens in a larger measure and paying their own way? Is there not widespread abuse of public and private philanthropic enterprises outside of that which in individual cases doubtless obtains in the care and treatment of ex-service men at the expense of the people?

Efforts have been made to put the medical service of the U. S. Veterans' Bureau on a better basis by creating a medical corps with commission status and permanent tenure and greater emolument, so that not only for the present but for the future the best type of young men coming into medicine will be attracted to this service as a career; and your careful consideration and cooperation in the furtherance of this desirable object is solicited by the director, the medical director and medical officers of the service. With the unequaled opportunity for research and for clinical observation and experience given the proper status and adequate compensation, the Veterans' Bureau Medical Service has the opportunity of not only giving to our ex-service men the highest type of medical skill, but by their work reflecting credit and glory on American medicine. We ask your constructive criticisms and your counsel and advice.

This communication was spread on the minutes for the information not only of the House but also for the Medical profession of the country at large.

The House recessed at 12:30 p. m.

Third Meeting—Thursday Afternoon, April 22

The House of Delegates was called to order at 2 p. m. by the Speaker, Dr. F. C. Warnshuis.

ELECTION OF OFFICERS

The Speaker asked for nominations for President.

Dr. E. J. Goodwin, Missouri, nominated Dr. Jabez N. Jackson. Dr. Jackson's nomination was seconded by Dr. Ben R. McClellan, Ohio; Dr. Arthur W. Booth, New York; Dr. A. W. Hornbogen, Michigan; Dr. Donald Macrae, Jr., Iowa; Dr. Walter F. Donaldson, Pennsylvania, and Dr. E. P. Sloan, Illinois.

Dr. Jabez N. Jackson was then unanimously elected, and the Speaker declared that he had been chosen President-Elect of the Association by the unanimous vote of the House of Delegates.

Nominations for Vice President were declared by the Speaker to be in order.

Dr. E. C. Ellett, Tennessee, nominated Dr. John O. McReynolds, Dallas, Texas.

Dr. Albert Soiland, California, nominated Dr. C. M. Rosser, Dallas, Texas.

Dr. A. T. McCormack, Kentucky, seconded the nomination of Dr. John O. McReynolds.

Dr. Thomas C. Chalmers, New York, and Dr. S. W. Welch, Alabama, seconded the nomination of Dr. Rosser.

The Speaker appointed as Tellers Dr. Albert Soiland, California; Dr. T. O. Freeman, Illinois; Dr. Carl F. Moll, Michigan; Dr. W. J. Ferguson, Missouri, and Dr. Harry de Vighne, Alaska.

Of the votes cast, Dr. McReynolds received 74 and Dr. Rosser, 55. The Speaker declared that Dr. McReynolds had received a majority of the votes cast and had been elected Vice President.

Presentation of President-Elect Jabez N. Jackson

The Speaker introduced the President-Elect, Dr. Jabez N. Jackson, who addressed the House as follows:

Mr. Speaker and Fellows of the House of Delegates:

From the bottom of my heart, with feelings which words cannot express, I wish to thank you for this high honor. I, like many of you, was born into medicine, as my father and two of my uncles were doctors before me. I started to attend medical society meetings and to become a member of the profession, as a matter of fact, before I even entered on the study of medicine.

The first meeting of the American Medical Association which I had the privilege of attending was at Newport with my father, at which time he was honored by election as First Vice President. He died at that time.

As a youngster, as soon as I was out of school I became a member of my local society, and since that time I have always worked actively in medical society affairs. In fact, I am one of those who firmly feel that institutions are worth more than individuals, and that any man who is worthy of membership in the grand profession of medicine should be one who thinks more of his profession as a whole than of his own individual ambitions or interests. So it comes to me, therefore, with great pleasure today to realize that my friends have honored me with this position.

I would be possessed of more vanity than I can summon if I accepted this as an expression of my individual strength. I accept it instead as a representative of that great imperial territory known as the Southwest, because it has been my friends in the Southwest who have believed in me and who have put my name up for your endorsement today. Yet at the same time, while appreciating the compliment to the Southwest and particularly to my friends of the Southwest, I also say that I appreciate most heartily the enthusiasm with which the whole mass of the delegates have supported me. I thank you again for this high honor. (Applause.)

Election of Secretary

Dr. J. A. Witherspoon, Tennessee, nominated Dr. Olin West for Secretary.

Dr. A. T. McCormack, Kentucky, seconded the nomination.

The Speaker announced the unanimous election of Dr. Olin West.

Election of Treasurer

Dr. J. H. Walsh, secretary of the Board of Trustees, stated that the Board of Trustees unanimously nominated Dr. Austin A. Hayden, Chicago, for Treasurer of the Association to succeed himself.

The Speaker announced the unanimous election of Dr. Austin A. Hayden.

Election of Speaker of the House of Delegates

The Vice Speaker was called to the Chair and declared that nominations were in order for Speaker of the House of Delegates.

Dr. E. Eliot Harris, New York, nominated Dr. Frederick C. Warnshuis.

Dr. S. W. Welch, Alabama, Dr. J. A. Witherspoon, Tennessee, and Dr. Carl F. Moll, Michigan, seconded the nomination.

Dr. Frederick C. Warnshuis was elected Speaker of the House of Delegates by unanimous vote.

Dr. Warnshuis resumed the Chair.

Election of a Vice Speaker

Dr. F. W. Cregor, Indiana, nominated Dr. Albert E. Bulson, Jr., Indiana, for Vice Speaker of the House of Delegates.

Dr. E. Eliot Harris, New York, seconded the nomination.

Dr. A. T. McCormack, Kentucky, nominated Dr. H. P. Linsz, West Virginia.

Dr. C. J. Whalen, Illinois, seconded the nomination of Dr. Bulson.

Dr. C. S. Gorsline, Michigan, seconded the nomination of Dr. Linsz.

Dr. Victor G. Vecki, California, seconded the nomination of Dr. Bulson.

Dr. E. C. Thrash, Georgia, nominated Dr. Allen H. Bunce, Georgia.

Nominations were closed, and Dr. Bunce was elected Vice Speaker of the House.

Election of Trustees

Dr. William Gerry Morgan, District of Columbia, nominated Dr. Charles W. Richardson to succeed himself.

Dr. A. T. McCormack, Kentucky, and Dr. Walter F. Donaldson, Pennsylvania, seconded the nomination.

The Speaker declared Dr. Charles W. Richardson elected unanimously.

As Trustee to succeed Dr. Joseph A. Pettit, Portland, Ore., Dr. Victor G. Vecki, California, nominated Dr. Ray Lyman Wilbur, California.

Dr. William Kuykendall, Oregon, nominated Dr. Joseph A. Pettit, Oregon, to succeed himself.

Dr. A. W. Hornbogen, Michigan, seconded the nomination of Dr. Pettit.

Dr. F. B. Lund, Massachusetts, Dr. Joseph F. Smith, Wisconsin, Dr. William H. Mayer, Pennsylvania, and Dr. Bertram L. Bryant, Maine, seconded the nomination of Dr. Wilbur.

Dr. Harry de Vighne, Alaska, seconded the nomination of Dr. Pettit.

Dr. E. C. Thrash, Georgia, Dr. George Blumer, Connecticut, and Dr. Arthur W. Booth, New York, seconded the nomination of Dr. Wilbur.

Dr. A. T. McCormack, Kentucky, seconded the nomination of Dr. Pettit

Dr. A. D. Dunn, Nebraska, seconded the nomination of Dr. Wilbur.

Dr. H. A. Miller, New Mexico, and Dr. H. P. Linsz, West Virginia, seconded the nomination of Dr. Pettit.

Dr. E. M. Neher, Utah, endorsed Dr. Pettit.

Nominations were closed. Of 119 votes cast, 59 were for Dr. Wilbur, and 60 for Dr. Pettit.

The Speaker declared Dr. Pettit elected to succeed himself as a member of the Board of Trustees.

For Trustee to succeed J. H. J. Upham, Columbus, Ohio, Dr. George Edward Follansbee, Ohio, nominated Dr. J. H. J. Upham, Ohio.

Dr. Thomas C. Chalmers, New York, Dr. D. E. Sullivan, New Hampshire, Dr. Samuel P. Mengel, Pennsylvania, Dr. F. B. Lund, Massachusetts, Dr. Charles E. Humiston, Illinois, and Dr. Arthur W. Booth, New York, seconded the nomination of Dr. Upham.

The motion to close the nominations was seconded and carried, and Dr. J. H. J. Upham, Ohio, was unanimously elected as Trustee.

For Trustee to fill the unexpired term of Thomas McDavitt, Dr. H. M Brown, Wisconsin, nominated Dr. Rock Sleyster, Wisconsin.

Dr. J. D. Brook, Michigan, Dr. J. L. Rothrock, Minnesota, and Dr. S. W. Welch, Alabama, seconded the nomination of Dr. Sleyster.

The Speaker announced the unanimous election of Dr. Sleyster to fill the unexpired term of Dr. Thomas McDavitt.

The Speaker announced that by the resolution or expression of sentiment of the House, the Trustee receiving the highest number of votes should serve for the period of five years. Two of the newly elected Trustees had received 138 votes each, Dr. Upham and Dr. Richardson. Dr. Upham, in view of the years of experience of Dr. Richardson, withdrew his name for the five-year term, and the Speaker declared Dr. Richardson the Trustee for a term of five years.

Nomination for Standing Committees

President Wendell C. Phillips presented to the House the following nominations to standing committees:

Judicial Council: Dr. J. N. Hall, Denver, to succeed himself.

Council on Medical Education and Hospitals: Dr. S. W. Welch, Alabama, to succeed himself.

Council on Scientific Assembly: Dr. John E. Lane, Connecticut, to succeed himself.

On motion of Dr. A. T. McCormack, Kentucky, regularly seconded and carried, the nominations were confirmed.

Election of Honorary, Affiliate and Associate Fellows

The Secretary read the following nominations for Associate and Affiliate Fellowship, all of which were confirmed by the House:

The Judicial Council nominated the following:

AMERICAN MEDICAL MISSIONARIES

Byram, Roy M., Kanghei, Korea.
Dunlap, R. W., Chefoo, Shantung, China.
Ewers, E. M., Weihsien, China.
Freas, Howard M., Banza, Manteke, Belgian Congo.
Griggs, Donald E., Nanking, China.
Hoyt, Hubbard S., Taikyu, Chosen, Japan.
Huffman, L. E., Pauri, Garhwal, India.
Lewis, Stephen C., Chenchow, China.
Meade, Richard H., Jr., Anking, China.
Morris, H. H., Shanghai, China.
Oechli, Waldo R., Taianfu, Shangtung, China.
Peterson, R. A., Nanking, China.
Southworth, J. D., Tennoji Ku, Osaka, Japan.
Taylor, Harry B., Anking, China.
Teusler, Rudolph B., Tokyo, Japan.
Wanless, W. J., Miraj, India.
Ward, Mark H., Boston, Mass.
Watson, Percy T., Shansi, China.
Webb, Adin H., Chengtu, West China.

APPLICANT LIVING IN ADJACENT COUNTRY

Dunlop, F. C., Vancouver, British Columbia, Canada.

The following nominations for Associate Fellowship were submitted by the sections named:

SECTION ON PHARMACOLOGY AND THERAPEUTICS

De Eds, Floyd, San Francisco.
Young, Albert Gaylord, Ann Arbor, Mich.
Tatum, Arthur L., Chicago.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Cope, Otis Merriam, Omaha.
Lewis, Robert C., Denver.
Reed, C. I., Dallas, Texas.
Rogers, Fred Terry, Dallas, Texas.
Steenbock, Henry, Madison, Wis.
Turley, Louis A., Norman, Okla.
Woods, Ozra T., Dallas, Texas.
B. C. H. Harvey, Chicago.
Roger Sanford Hubbard, Clifton Springs, N. Y.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Carter, William S., New York.
Russell, Paul F., Malacca, Straits Settlements.
Turner, Clair E., Boston.

AFFILIATE FELLOWS

Wesseler, F. W., St. Louis.
Brown, Tinsley, Hamilton, Mo.

Place of 1927 Annual Session

Dr. William Gerry Morgan, District of Columbia, nominated Washington, D. C., and read the following invitation: "The Medical Society of the District of Columbia invites you to hold the Seventy-Eighth Annual Session in Washington, D. C., the capital city of the nation. Our delegate, Dr. William Gerry Morgan, has been instructed to present this invitation at the Session of the House of Delegates, April 19, in Dallas, Texas."

Dr. Albert Soiland, California, seconded the motion to go to Washington.

Dr. Charles W. Richardson, Washington, D. C., seconded Washington and spoke in its favor.

Dr. Peter W. Tomlinson, Delaware, seconded Washington.

Dr. M. A. Tate, Ohio, nominated Cincinnati.

Dr. E. Eliot Harris, New York, seconded the nomination of Washington.

Dr. George Edward Follansbee, Ohio, seconded the nomination of Cincinnati.

Dr. J. L. Rothrock, Minnesota, nominated St. Paul. Dr. H. M. Johnson, Minnesota, seconded the nomination of St. Paul.

The Speaker anounced the selection of Washington, D. C., as the next meeting place.

Dr. Holman Taylor read the supplementary report of the Reference Committee on Reports of Board of Trustees and Secretary:

Supplementary Report of Reference Committee on Reports of Board of Trustees and Secretary

TRUSTEES

We consider here several matters not referred to in our previous report. It is not feasible to present the thorough digest which the importance of the report of the Board of Trustees deserves. The report itself should by all means be carefully studied by each member of the House of Delegates.

This seems to have been a prosperous year for the Association, and our committee feels that the Board of Trustees deserves the appreciation of this House and of the Association for its successful endeavors, and for its business acumen. We note that at the close of the fiscal year the Association had gained for its reserve the sum of $45,121.96. It will be necessary to study the report of the auditor (Hand Book, p. 89) in order to appreciate fully the financial status of the Association, which we trust at least the members of the House of Delegates will do.

The increase in Fellowship and outside subscriptions to The Journal, and in its advertising constitute indisputable evidence of prosperity. It will be borne in mind that the advertising income of The Journal could be greatly increased by even slight modifications of the high ethical standards at present in force. It will also be borne in mind that the American Medical Association assumes its membership automatically, but must depend on the appreciation of the individual for its Fellowship.

The value of the Spanish edition of The Journal has been thoroughly established, and it is the opinion of our committee that its publication should be continued. It will be noted that the net loss in the publication of this journal was $11,740.10, a decrease in loss of $1,161.95. It will be noted, further, that the Rockefeller Foundation bears half this loss.

The special journals all show an increase in subscription, except for one that was established during the year, and four of them have been published at a profit of from two to five thousand dollars each. These several enterprises would seem to be worth while.

The net cost of the Quarterly Cumulative Index was $12,678.53. The value of this publication warrants this expenditure, we are sure.

We are pleased to note that the Directory begins to show a gain on the credit side of the ledger, even though the gain is apparent rather than actual, as stated by the Trustees. It might be observed in this connection that most of the overhead utilized by this publication and not charged to it would exist, regardless of this special demand.

The increase in circulation and decrease in net cost of *Hygeia* is noted with much satisfaction. It is more than ever clear that this publication will eventually be the success we have hoped for in the most important field of health education. Every member of this great Association should be made to feel his responsibility for the circulation of *Hygeia*. It would be in the homes of every patient of every reputable physician in this country if this were so.

The Council on Pharmacy and Chemistry continues to merit the approbation of the medical profession for the great service it renders the cause of scientific medicine. We should appreciate, perhaps more than we do, the valuable services, without remuneration, rendered by the members of this council. We feel that the recently noticeable reduction in quackery is largely due to the scientific work of the Council on Pharmacy and Chemistry.

The development of the scientific exhibits and the motion picture theater factors in the scientific instruction work of the Association appeals to us as being of large importance.

The plan of medical relief in disaster advanced by a special committee, composed of Drs. William Allen Pusey, W. D. Haggard and Wendell C. Phillips, which will be found on page 103 of the Hand Book, and which has been fully endorsed by the Trustees, should be adopted. On representations made by the aforesaid committee, it is recommended that the designation of this plan be changed from "Disaster Relief" to "Medical Relief in Disaster." This is an important matter, and the plan has evidently been carefully worked out. It is provided that the general manager of the American Medical Association shall be the national director of medical relief in any large disaster, and the presidents of state societies shall be liaison officers between the national headquarters of the Association, state headquarters and component county societies. Presidents of district and component county societies shall be local directors, but may deputize other members of the profession to serve in their stead. It might be well to alter the plan set out by the committee so as to permit also the executive secretaries of state medical associations instead of the presidents, at the option of the national director of medical relief in disaster, to serve as state directors.

Of special interest is the discussion of "Narcotics" to be found on page 69 of the Hand Book. The activities of the Trustees in avoiding the very aggravating requirement that physicians prescribing narcotics register also as dispensers of narcotics constitute a service to be appreciated.

The Board of Trustees is to be commended for the spirit shown in supporting the decision of the House of Delegates to disapprove of the provisions of the World War Veterans' Act of 1924, which law granted hospitalization to all veterans, regardless of financial need, ailment or connection with war service. We recommend continuation of their activities in this connection, in view of pending federal legislation looking to the extension of the privilege of outpatient treatment under the same conditions.

The approval of certain chiropractic schools by the United States Department of Labor, as per discussion beginning on page 74 of the Hand Book, is to be condemned as encouraging quackery, and the Board of Trustees should see that every proper effort is made to have such approvals canceled.

We consider the matter of "Cults in Hospitals" to be rather local than general. The Board of Trustees should render to state associations such assistance in solving problems of this sort as may seem agreeable and advisable.

The Board of Trustees has promptly and vigorously carried out the purpose of the resolution adopted by the House of Delegates last year, in regard to the publication of reports, resolutions and the like, pertaining to policies of the Association, thirty days in advance of the annual meeting. It has the appreciation of the House of Delegates for this service.

The very prompt establishment of the Council on Physical Therapy, with such a high order of personnel and on a permanent basis, is another highly appreciated service of the Board of Trustees. We feel that the personnel of this council and the rules adopted for its guidance will insure results of the greatest value.

Finally, our committee appreciates the enormousness of the work of the Board of Trustees and the completeness of its report. And in this connection, and for this reason, we feel that it would not be amiss to urge that the House of Delegates select the personnel of the Board with the utmost care The management of such a great enterprise as the American Medical Association requires, in addition to other qualities, business ability of the highest order.

SECRETARY

The Secretary has submitted a most satisfactory report, from the standpoint of subjects treated and the manner of their treatment. It does not appear to our committee necessary or desirable to go greatly into detail in its consideration. It is believed that each member of the House of Delegates has carefully read this report, and if there are any who have not, it is respectfully urged that they do so at once. It is also urged and advised that this report be brought to the attention of constituent state associations and component county societies.

The largest membership in the history of the Association is reported. There are now 91,792 members, which makes the Association the largest of its kind in the world. In this connection should be noted the complaint of the Secretary that the carelessness of members of county societies, at which point lies the source of membership of the American Medical Association, is costing the Association good money. It is estimated that it costs not less than $1 per member to reinstate those who have allowed their memberships to lapse. This matter should be brought forcefully to the attention of component county societies, through their respective state associations.

The healthy increase in fellowship noted by the Secretary is an indication of a wholesome growth of appreciation of the national body, and we are hopeful that the growth will continue as rapidly as conditions will permit.

There are now 58,681 Fellows, an increase of 2,493 for the year. It will be remembered that our membership is coincident with the membership of component county societies, but our Fellowship is individually and separately acquired. The value of Fellowship is not by any means exclusively to the individual The educational influence of The Journal, alone, is worth much to the group Our basic purpose is a better educated and a more effective medical profession, and any factor that serves this purpose is worth while.

The county society should be the fountain head of scientific work The secretary very properly points to a danger in this connection The scientific program of a county society should accomplish two distinct things, instruct the membership and develop in members the scientific ability and the ability to express themselves. If these programs do not bring to the society those who are qualified to speak and able to speak, instruction will suffer. On the other hand, if this is done to the exclusion of discussions by members generally, there will be no development State associations and county societies will do well to give special study to this problem

The component county society constitutes the basis of the American Medical Association from every point of view. If the American Medical Association would succeed in the highest degree, it must develop the county societies to the highest degree, and require of them that they function, as it was originally intended that they should function. It is sometimes expedient to shortcircuit the county society, but if this is done to any considerable extent the whole organization will pay a penalty that might and should be avoided.

We feel that the annual conference of secretaries of constituent state associations is proving of great value. We trust that the Board of Trustees will continue to foster this practice One of the most difficult tasks confronting our national organization is that of coordinating the activities of constituent state associations and bringing about the maximum uniformity of laws and regulations for their government. There can be no better agency for this purpose than the annual conference of state secretaries.

Respectfully submitted.

E. Eliot Harris, Chairman,
C. J. Whalen,
Holman Taylor,
E. J. Goodwin,
A. H. Bunce.

On motion of Dr Taylor, seconded by Dr. Albert Soiland, California, the report of the Reference Committee on Reports of Board of Trustees and Secretary was adopted.

Presentation of Distinguished Guests

Dr. J. O. McReynolds presented the director of the National University of Mexico, Dr. Alfonso Pruneda, and his distinguished colleagues of the Mexican Republic.

Dr. Alfonso Pruneda said:

Mr. Speaker and Gentlemen of the House of Delegates:

The Mexican delegation deeply appreciates your hospitality and begs to convey its greetings to you. We have been interested in the wonderful work done by the American Medical Association. We sincerely appreciate The Journal, and the contribution of this Association not alone to medical science, but to medical ethics and to social and human welfare. We hope that this personal acquaintance may help us more and more to form a closer bond with the people of the States, and especially the medical men of the country. [Applause.]

In behalf of the Association, the Speaker extended greetings to Prof. J B. Collip, Edmonton, Alta., who represented the Canadian Medical Association, and Chester A. Duncan, dean of Pharmacy of Baylor University, delegated to represent the American Pharmaceutical Association.

Supplementary Report of Board of Trustees

Dr. Edward B. Heckel, Board of Trustees, read a supplementary report from the Board with respect to the letter from the National Catholic Welfare Conference, which had been referred to the Board. The Board recommended that in the absence of data based on adequate scientific investigation, the House of Delegates express no opinion on pending legislation.

Dr. A. D. Dunn, Nebraska, moved the adoption of the report of the Board of Trustees.

The motion was seconded by Dr. John P. DeWitt, Ohio.

Dr. Southgate Leigh, Virginia, moved that it be referred back to the Board of Trustees with power to act.

The motion was seconded by Dr. Arthur W. Booth, New York.

The Speaker announced that the vote to refer the matter back to the Board of Trustees had carried.

Supplementary Report of Reference Committee on Reports of Officers

Dr. Arthur W. Booth, New York, read the supplementary report of the Reference Committee on Reports of Officers:

1. Your Committee begs to report that it heartily endorses the suggestions and recommendations of President Haggard relative to the proposed plans for extending the idea of periodic health examinations.

Your committee feels that the efficiency of this general movement will depend largely on the care exercised in preparing the literature to be sent out by the various county societies to their members and the lay public. To that end, we suggest that the Trustees should be requested to prepare sets of carefully worded letters as approved models or forms.

2. In reviewing the address of President-Elect Phillips, we found many constructive suggestions designed to bring the general public into intelligent cooperation with organized medicine. We approve of Dr. Phillips' suggestions that the House of Delegates urge on every practitioner of medicine his personal duty in this matter, and especially the necessity for an intensive survey to determine the most efficient methods of promoting public health education and impressing the public with the necessity of such. We therefore offer the following resolution:

Resolved, That the House of Delegates requests the Board of Trustees to appropriate sufficient funds to defray the expenses of a survey, the purpose of which shall be an investigation of ways and means to best promote public health education.

3. We heartily approve of the Speaker's comments touching on state medicine and contract practice.

4. As regards the subject of selecting a place for the annual session, we agree thoroughly with the Speaker that there are many questions involved in the selection of a suitable place for our annual sessions, and that the Board of Trustees is in a position to obtain more definite and satisfactory data than the individual members of the House of Delegates. We feel, however, that, within certain limits, the members of the House of Delegates ought to have a voice in the designation. We would therefore recommend that the Board of Trustees be requested to suggest, at the first meeting of the annual session, not less than three suitable locations, and that from these, the House of Delegates shall make the final choice by vote.

Respectfully submitted.

Albert E. Bulson, Jr.
J. Norman Henry.
William Gerry Morgan.
Victor G. Vecki.
Arthur W. Booth, Chairman.

Dr. Albert Soiland, California, moved the adpotion of the report as a whole.

The motion was seconded by Dr. Albert E. Bulson, Jr., Indiana, and carried.

Supplementary Report of the Committee on Legislation and Public Relations

Dr. H. M. Brown, Wisconsin, stated that the resolution of expert opinion evidence was referred back to the committee with an addendum for its consideration and for the introduction of new evidence. That new evidence in the matter has been heard and carefully analyzed by your committee, and following will be the report of the committee as to the motion brought before the House at the first session. That motion as amended now reads as follows. Dr. Brown read the resolution and a telegram from the professor of criminal law, University of Pennsylvania:

Whereas, The present court procedure in expert opinion evidence in both civil and criminal cases has in many instances brought public criticism and disgrace on both the legal and the medical professions; and

Whereas, The present procedure in many cases is believed to defeat the administration of justice; and

Whereas, An effort is being made in many states by the bar associations and medical societies of those states to correct such maladministration of justice, and to relieve the legal and medical professions of the public criticism now received; and

Whereas, The American Bar Association is actively pursuing the above laudable effort; therefore, be it

Resolved, By the House of Delegates of the American Medical Association that it recognizes the urgent need for such remedial legislation and such change in court procedure as will correct the abuse of expert opinion evidence; approves the efforts of the various bar and medical associations; and further be it

Resolved, That the House of Delegates endorses the principle that in civic and criminal cases the court may appoint expert medical witnesses, who shall be paid out of public funds, and who may furnish a written report; and that the American Medical Association offers its cooperation by such means as lie in its power to promote such legislation as will be mutually satisfactory to the medical and legal professions toward the correction of the present unsatisfactory procedure of presenting expert opinion evidence, and the Board of Trustees is hereby requested to use the facilities of this organization in such a way as to give effect to the sentiments expressed in this resolution.

And further that the House of Delegates endorses certain principles approved by the Committee on Jurisprudence and Legal Reform of the American Bar Association, and by the American Institute of Criminal Law and Criminology as follows:

That in civil and criminal cases where the issue of insanity is raised, expert medical witnesses may be appointed by the court, and paid from public funds, and that such witnesses may present a written report.

Be it further

Resolved, That a copy of this resolution be sent to the American Bar Association.

Respectfully submitted.

Horace M. Brown, Chairman.

TELEGRAM

April 21, 1926.

Dr. J. Norman Henry, Dallas, Texas.

Testimony bill approved by Committee on Jurisprudence and Law Reform of American Bar Association 1915, by American Institute of Criminal Law and Criminology 1914, by eleventh annual conference of American Medical Association on Medical Legislation called by Council on Health and Public Instruction, Chicago, Feb. 15, 1915. These approvals verified.

E. R. Keedy, Philadelphia.

Professor of criminal law, University of Pennsylvania; chairman of committee which drafted those principles.

Dr. H. M. Brown, Wisconsin, moved the adoption of the resolution. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

Dr. Brown begged the privilege of presenting the copy of the article referred to in the report.

The Speaker stated that it would be attached as addenda to the complete report.

Dr. Brown had a further resolution referring to H. R. 10125, a bill in Congress endeavoring to bring about the same general class of changes. Dr. Brown read the resolution:

Resolved, That the House of Delegates of the American Medical Association endorse the principles embodied in H. R. 10125, a bill to provide for the coordination of the public health activities of the government and for the other purposes.

On motion by Dr. Brown, seconded by Dr. Arthur J. Bedell, New York, the resolution was adopted.

Dr. Brown moved the adoption of the report as a whole. The motion was seconded and carried.

Supplementary Report of Reference Committee on Hygiene and Public Health

Dr. C. E. Mongan, Massachusetts, Chairman of the reference committee, read the report, recommending that the committee to study cosmetics be continued, and moved the adoption of the report. The motion was seconded by Dr. J. W. Van Derslice, Illinois, and carried.

Supplementary Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. J. W. Van Derslice, Illinois, stated that the amendment submitted by Dr. Eagleton, New Jersey, referring to an ad interim meeting, was recommended to be not adopted, and so moved.

The motion was seconded by Dr. C. E. Mongan, Massachusetts, and carried.

The committee recommended that the amendment offered by the Delegate from Missouri, which would place on the free list of The Journal the affiliate members of the Association, be not adopted. Dr. Van Derslice moved the adoption of that portion of the committee's report. The motion was seconded by Dr. Albert E. Bulson, Jr., Indiana, and carried.

The supplementary report of the Judicial Council in supporting an amendment to the Constitution was submitted, and the committee recommends that we adopt this amendment to the By-Laws. Dr. Van Derslice read the portion of the report of the Judicial Council referred to:

Membership in the American Medical Association is regularly obtained through membership in a constituent association and in one of its component county societies. Should a qualified physician, however, be refused membership in his component county society, he may appeal his case to the board of censors or proper tribunal of the state association in the manner provided for in the by-laws of the particular county society and state association. Should the appeal tribunal, after a careful, fair and unbiased hearing of the case, find the appellant to be worthy of membership in the organization, and should the tribunal after reasonable efforts fail to reconcile the county society to the acceptance of the appellant as a member of the said society, the house of delegates of the constituent state association, on the recommendation of the appeal tribunal, may elect the said appellant a member of the state association, the appellant thereby becoming a member of the American Medical Association.

Should any member of the American Medical Association be deemed by the Judicial Council to be unworthy of membership in the said Association, it shall be the duty of the Secretary, on the recommendation of the Judicial Council, to notify the secretary of the said member's constituent association and he in turn the secretary of the said member's component society of the facts in the case; and should the state association and the local society fail to take proper action in the premises, the House of Delegates, on the recommendation of the Judicial Council, may expel the said member from the American Medical Association.

Dr. Van Derslice moved the adoption of the amendment. Seconded by Dr. E. C. Thrash, Georgia.

Dr. H. M. Brown, Wisconsin, moved that the amendment be laid on the table. The motion to table was seconded by Dr. Thomas C. Chalmers, New York. The vote was 26 in favor of tabling and 26 against. The Speaker declared the motion to lay on the table carried.

Dr. J. W. Van Derslice, Illinois, moved that the report of the committee as a whole be adopted. The motion was seconded by Dr. Bedell, New York.

The Speaker explained that the question was on the adoption of the report as a whole, with the exception of the latter part, which was laid on the table and not adopted. The motion to adopt the report carried.

The Speaker presented for consideration a question of program of the House, having noticed that each year during the day of the last session after the election has been completed a large number of delegates depart. While a quorum is present, there is not as full a representation of delegates as would be desirable. It would seem, therefore, somewhat advisable that some procedure be given notice of at this time for enaction next year that will provide for the receipt of the reference committee reports before the House proceeds to the election. That can be done on Tuesday afternoon or Wednesday morning, but is an important matter in the affairs of the Association. With all due respect to the members who are diligent in attending to their duty, somebody can ride through a pretty dangerous piece of legislation at the last session of our House. The Speaker suggested that some member rise and give notice that he is going to introduce an amendment to either the Constitution or the By-Laws next year so we can act on that.

Dr. H. M. Brown, Wisconsin, undertook the responsibility and gave such notice.

Unfinished Business

Dr. O. S. Wightman, New York, read two telegrams, one signed by D. S. Dougherty, secretary of the Medical Society of the State of New York, and the other by Dr. Henry L. K. Shaw, Chairman of the Committee on Legislation. They read as follows:

> Medical Practice Act passed the Senate, vote 35 to 12.

Dr. Wightman continued that Governor Smith had already said that he would sign the bill—an epoch in medical legislation.

Dr. Wightman offered the following resolution:

> The medical profession of the United States as represented by the American Medical Association in convention at Dallas, Texas, congratulates the governor of the state of New York in his demand for higher standards of medical education and the protection of the health of the citizens of the empire state so well outlined in his legislative message on assuming office. We further pray that there may be no deviation from this course and ask that full consummation be realized by affixing his signature approving the medical practice act recently passed by the legislature of the state of New York.

Dr. T. C. Chalmers, New York, said: This does what to my mind is the greatest thing that has been done yet in medical legislation; it creates a grievance committee based on the grievance committee of the Bar Association, which makes instead of twelve jurors a committee of grievance composed of ten doctors of conspicuous medical standing. I trust this endorsement will prevail.

President Wendell C. Phillips said: I feel that at last the medical profession of the state has been able to convince legislators that it is their duty to look after the public health. We have developed enough knowledge of public health affairs in our legislature so they are doing it for their own protection, and that is the kind of a bill we passed. I sincerely hope it will be adopted.

A motion was made by Dr. O. S. Wightman, New York, seconded by Dr. John P. DeWitt, Ohio, that the resolution be adopted.

The Speaker announced that the resolution was unanimously adopted.

The Secretary read the following resolution from the Section on Preventive and Industrial Medicine and Public Health:

> *Resolved,* That the section on Preventive and Industrial Medicine and Public Health approves the following resolution and urges its adoption by the House of Delegates:
>
> Whereas, The registration of births and deaths at the time of their occurrence furnishes official record information of much value to individuals; and
>
> Whereas, The registration of deaths, with information on certain points, is essential to the progress of medical and sanitary science in preventing and restricting disease and in devising and applying remedial agencies; and
>
> Whereas, All the principal countries of the civilized world recognize the necessity for such registration and enforce the same by general laws; and
>
> Whereas, There are still seven states which either have defective death registration laws or have death registration less than 90 per cent complete; and
>
> Whereas, There are still fifteen states which either have defective birth registration laws or have birth registration less than 90 per cent complete; and
>
> Whereas, After a twenty-five year campaign to secure nation-wide registration of births and deaths, a drive is now on to reach this goal before 1930; now, therefore, be it
>
> *Resolved,* By the House of Delegates of the American Medical Association in annual meeting assembled, that the American Medical Association hereby expresses approval of this movement and requests the favorable consideration and action of the state authorities, to the end that good state laws for the registration of births and deaths may be enforced and that national registration of births and deaths may become a reality before 1930.

Dr. C. E. Mongan, Massachusetts, moved that the resolution be adopted. The motion was seconded by Dr. Albert E. Bulson, Jr., Indiana, and carried.

The Secretary read the following resolution from the Section on Laryngology, Otology and Rhinology:

Recognizing the fact that the most effective means for the prevention of deafness consists in the early detection of hearing impairment, thereby giving opportunity for the prompt removal of contributing causes, and believing it to be one of the important functions of our public school authorities to safeguard the integrity of the special sense organs as well as the general health of the school child; be it

Resolved, By the Section on Laryngology, Otology and Rhinology of the American Medical Association that it heartily favors the provision by our public school authorities for regular, periodic examinations of the hearing acuity of all public school children, such examinations to be adequate to detect even slight degrees of hearing loss; and be it further

Resolved, That this resolution be referred to the House of Delegates of the American Medical Association for its endorsement.

Dr. E. C. Thrash, Georgia, moved that the resolution be adopted. The motion was seconded by Dr. S. M. Blackshear, Louisiana, and carried.

Resolution of Thanks to Dallas

Dr. J. W. Van Derslice, Illinois, introduced the following resolution:

Resolved, That the House of Delegates on behalf of the members of the American Medical Association extend our hearty thanks and appreciation to the citizens of Dallas, the press of the city, the Dallas County Medical Society, the Texas State Medical Society, to Dr. Cary as chairman of the Local Committee of Arrangements, and any and other person who has contributed to the welfare and the interest and the success of this session that we have just completed.

Dr. Van Derslice moved the adoption of the resolution. The motion was seconded by several Delegates and adopted unanimously.

Death of Dr. Francis

Dr. Albert E. Bulson, Jr., Indiana, called attention to the fact that Dr. L. M. Francis, of Buffalo, a prominent member of the Association, had dropped dead at noon. He had been a member of the Association many years and had served in the House of Delegates. It was moved, seconded and carried that a telegram of condolence be sent to the relatives, and especially to Mrs. Francis.

The House of Delegates adjourned sine die at 5:25 p. m.

THE SCIENTIFIC EXHIBIT

Those who attended the Scientific Exhibit at Dallas were impressed by the scientific character of the exhibits, and the unusual amount of investigative work. The personal demonstrations by leaders in research were an outstanding feature. This year a number of papers in the sections were correlated with scientific exhibits, and notice of such correlation was published in the official program; this permitted more detailed discussion at the booths with the particular exhibit serving as a means of illustration.

The Section on Dermatology and Syphilology had another of its attractive exhibits, this time dealing with cancer. The committee in charge, composed of Drs. I. L. McGlasson, E. D. Crutchfield and Fred Weidman, deserve praise for the systematic presentation of the subject by the investigators who collaborated. Two special exhibits, authorized by the Board of Trustees, were always the centers of groups of interested visitors. The fresh pathologic exhibit received surgical and necropsy material from Dallas, supplemented by material from other cities, and by specimens received from the packing house at Fort Worth; the material was admirably demonstrated by Drs. George T. Caldwell and Ozro T. Woods. The exhibit on immunology was particularly instructive and the demonstrations were of practical, everyday interest. School children were present twice each day for demonstration of Schick and Dick tests. The committee in charge was composed of Drs. H. R. Wahl, Esmond R. Long, R. W. Lamson, J. H. Black and O. B. Nesbit. A coordinate exhibit on smallpox vaccination was given under the auspices of the United States Public Health Service by Dr. J. P. Leake. At stated intervals Dr. Leake showed the various types of takes, 120 students having been vaccinated a number of days previous to the opening of the session. Physicians also took advantage of the immunologic and smallpox demonstrations.

Except in the educational classification (where the work of organizations is exhibited), the material was presented in the name of the individual and not in the name of the institution where it was done, though the name of the institution appeared as part of the address. In line with this, the awards were made to individuals.

The arrangement of the exhibit was ideal, with spacious avenues and interesting aisles. The space utilized was almost 25 per cent larger than at Atlantic City. The total number of exhibits was seventy-seven, and the number of participants, 145.

REPORT OF COMMITTEE ON AWARDS

SCIENTIFIC EXHIBIT

The Committee on Awards reports:

The gold medal to Aldo Castellani, Department of Tropical Medicine, School of Medicine, Tulane University of Louisiana, New Orleans, for an exhibit on some tropical mycoses and their causative agents. The award is based on the excellent original investigations in a comparatively unexplored field of medicine, and for the perfection of display.

The two silver medals are awarded to the following (alphabetically arranged):

F. W. Hartman, Adolph Bolliger and H. P. Doub, Detroit, for exhibit showing the development of a promising experimental method and studies of nephritis.

Francis Carter Wood, Institute of Cancer Research, Columbia University, New York, for the introduction of an experimental method and for studies of sarcoma, and for excellence of demonstration.

The bronze medals are awarded to the following (alphabetically arranged):

Montrose Burrows, Louis H. Jorstad, Charles Johnston, G. Payling Wright and Edwin C. Ernst, St. Louis, for work showing the relation of vitamins to cancer.

Russell L. Haden, University of Kansas, Kansas City, Kan., for bacteriologic study of periapical dental infections.

The committee also awards certificates of merit to:

Janet Caldwell and Ozro T. Woods, Baylor Hospital, Dallas, for demonstration of bacteriophage.

Herbert Fox, Philadelphia, for exhibit of cancer in wild animals.

Preston G. Hickey, University Hospital, Ann Arbor, for roentgen-ray studies of injected pathologic material.

Alexander Lambert, New York, and George Blumer, New Haven, Conn., for demonstration dealing with modern methods of heart study, particularly angina pectoris.

A. H. McIndoe and V. S. Counsellor, Mayo Clinic and Mayo Foundation, Rochester, for study and excellence of presentation of injection and corrosion specimens of the vascular radicles of the liver and biliary tract.

Arthur M. Yudkin, Yale University of Medicine, New Haven, Conn., for ocular disorders attributable to dietary deficiencies.

Honorable mention is given to the following (arranged alphabetically):

American Social Hygiene Association, New York, for exhibits illustrating the work of Drs. Brown and Pearce, Rockefeller Institute.

Vilray P. Blair, St. Louis, for corrections of single harelip.

Samuel Iglauer, George Benzing, Samuel Brown and H. Kennon Dunham, Cincinnati General Hospital, Cincinnati, and Warren C. Breidenbach, Dayton, Ohio, for injected iodized oil in the roentgen-ray diagnosis of tracheal and bronchopulmonary conditions.

I. P. Leake, United States Public Health Exhibit, Washington, for excellent demonstration of actual smallpox vaccination.

United States Bureau of Entomology, Dallas, for some insects and related forms which attack man.

F. B. Young and A. L. Cooper, Scottsbluff, Nebraska, for original investigations in fossil and prehistoric pathologic conditions.

The committee appreciates the work of the two special committees, that of the Committee on Immunology and the Committee on Fresh Pathology, and feels that these features, which are not open to awards, deserve special praise. The committee would like to see these exhibits continued for next year.

The committee commends the fact that legends have been carefully prepared for many exhibits, but suggests that the purpose of the exhibit with fully explanatory legends should be most carefully worked out in the case of all exhibits.

The committee desires to commend the general arrangement, neatness, lighting and freedom from confusion of the Scientific Exhibit, and recommends it as a model for future exhibits. The committee has been impressed by the fact that there have been competent demonstrators in charge of most of the exhibits.

Roger Morris, Chairman.
Bundy Allen.
R. G. Hoskins.
W. L. McBride.
D. B. Phemister.

THE MOTION PICTURE THEATER

The Motion Picture Theater, which is under the management of the Scientific Exhibit, was located in an improvised auditorium adjacent to the Scientific Exhibit. As has characterized this feature during the last four years, the theater was operated strictly on schedule from noon to 5:30 on Monday, from 9 to 5:30 on Tuesday, Wednesday and Thursday, and from 9 to 4 on Friday. Thirty-four speakers were scheduled for seventy-five periods. The talks, which were of practical interest, were exceedingly well attended, at times the seating capacity (800) being overtaxed. At 5:30 on Wednesday afternoon a film on periodic health examinations was shown to an invited group, the members of which later will be asked for advice concerning the undertaking of such a feature film by the American Medical Association. The film was generously lent to the American Medical Association through the courtesy of the New York Tuberculosis and Health Association, with the cooperation of Drs. Orrin Wightman and Alec Thomson.

REGISTRATION AT DALLAS

The total registration at the Dallas Session was 4,179. Below are given two summaries, one by sections and one by states:

REGISTRATION BY SECTIONS

Practice of Medicine	1,371
Surgery, General and Abdominal	814
Obstetrics, Gynecology and Abdominal Surgery	239
Ophthalmology	205
Laryngology, Otology and Rhinology	213
Diseases of Children	174
Pharmacology and Therapeutics	16
Pathology and Physiology	83
Nervous and Mental Diseases	97
Dermatology and Syphilology	86
Preventive and Industrial Medicine and Public Health	92
Urology	132
Orthopedic Surgery	70
Gastro-Enterology and Proctology	51
Radiology	136
Miscellaneous	400
Total	4,179

REGISTRATION BY STATES

Alabama	28	Nebraska	39
Arizona	10	New Hampshire	2

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Illegal Practitioners Convicted.—The Etowah County Medical Association recently instituted quo warranto proceedings against a "Dr." M. R. Ferguson who is said to have practiced without a license at Attalla. Convicted by a jury, he has appealed the case to the state supreme court, claiming, it is said, that he did not prescribe medicine. The Alabama law does not require for conviction, that an illegal practitioner treat a patient, as merely offering to treat patients subjects him to prosecution.——Chester V. Ross, chiropractor at Mobile, was convicted by a jury of practicing without a license and was fined $50, April 8, it is reported.

ARKANSAS

Health Officer Appointed.—Dr. William K. Murray, of Canton, Ohio, has been appointed health officer of Little Rock, effective, May 1, to succeed Dr. William L. Holt, resigned. Dr. Murray is said formerly to have been attached to the departments of health of Chicago and of Canton, and to have served overseas during the World War.

State Medical Meeting.—The fifty-first annual session of the Arkansas Medical Society will be at Hot Springs National Park, May 18-20, with headquarters at the New Arlington Hotel. Among the speakers at the public session, May 18, will be Dr. Margaret W. R. Koenig of the state board of health, and Mr. Eugene T. Lies, a representative of the Playground and Recreation Association of America. There will be a clinical session at the government bath house, and visits to the various bath houses. The president's reception and dance will be in the evening of the second day. Among the speakers at the scientific session will be Dr. Fred H. Albee, New York, whose subject will be "Rehabilitation Surgery."

COLORADO

Hospital News.—The new Boulder Community Hospital, which is nearing completion, has been completely financed by a bond issue of $40,000, and a subscription campaign, which raised $72,000.——The second unit of the Methodist Episcopal Sanatorium at Colorado Springs will be opened by May 15; it has a capacity of fifty-five beds.

Personal.—Dr. Leonhard Koeppe of Halle, Germany, recently conducted a course of study in Denver on "The Slit Lamp and the Corneal Microscope."——Dr. Thomas C. Taylor, Fort Collins, has been reappointed county health officer. ——Dr. Helen F. Craig Sullivan, for many years pathologist at the St. Joseph's Hospital, Denver, has resigned. ——Dr. Ralph K. Collins, Trinidad, has arrived in Constantinople, Turkey, to make a health survey on behalf of the Rockefeller Foundation; it is planned to send a number of Turkish physicians and nurses to the United States to study American health methods.

DISTRICT OF COLUMBIA

Medical Inspection in the Schools.—Efforts are being made by school officials and members of the board of education of the District of Columbia to have Congress enact legislation placing school medical inspection in the hands of the school authorities of the district instead of in the district health department. The school officials have not at any time complained of the work performed by the health officer, but they fear there may be serious limitations on this work because of the ruling referred to above. The Monday Evening Club, which is a civic organization, advocates a large medical inspection program in the schools and has made a survey of this work in the district schools as compared with schools of other cities throughout the country. According to Walter Hatch, chairman of the health committee of the club, the survey shows that Washington is far behind other cities in the work of medical inspection in the public schools.

Lack of Funds for Health Work.—Failure of the director of the budget to approve, and of Congress to appropriate, adequate funds for health work in the District of Columbia was denounced by Health Officer, Dr. William C. Fowler, and others at the annual meeting of the Washington Council of Social Agencies at the Burlington Hotel, April 13. General criticism of health conditions in Washington was charged to the lack of funds by Dr. Victor C. Vaughan, chairman, Division of Medical Sciences, National Research Council. He gave statistics showing the death rate from various diseases, and emphasized that Washington is behind other cities in civic health activities. He pointed out that in 1925 the death rate from typhoid fever in Washington was more than five persons to 100,000 population, as compared with 1.5 for Norfolk, Va.; 3.3 for Wilmington, Del., and 3.6 for Baltimore. Dr. Vaughan said there is no prenatal clinic under government control; no maternity hospital under the control of the health officer, and no adequate supervision of preschool children. These and other conditions he laid to the lack of appropriations. James A. Tobey of the Institute for Government Research advocated the application of a standard to the district to determine what is wrong with the method of dealing with the health situation. Dr. Fowler explained the hopelessness of the health department functioning as it should in many cases as due to lack of funds. "We have asked for an appropriation of $25,000 to suppress any form of nuisances attributed to nonresidents here," he said, adding that the appropriation granted was only $2,000.

FLORIDA

Miscellaneous Items.—Dr. Simon E. Driskell, Jacksonville, has been appointed a member of the state board of medical examiners.——The Dade County Medical Society recently voted to raise its annual dues to $50.——A municipal hospital is being constructed for Delray to be made of several units, the first of which will cost $25,000.

State Medical Meeting.—The fifty-third annual meeting of the Florida Medical Association will be held in Gainesville, May 4-5. Registration will be conducted at the Elk's Club; the Alachua County Medical Society will give a smoker, Monday evening, May 3; a banquet and dance will be given Tuesday evening at the White House Hotel; automobile drives, bridge parties, luncheons and visits to the University of Florida have been arranged. There will be a general meeting, May 4, at 12:15, and a meeting of the house of delegates at 5. The scientific assembly meets May 4 at 2, and in the morning and afternoon, May 5. The speakers will comprise many of the prominent physicians of the state.

ILLINOIS

State Medical Meeting.—The seventy-sixth annual meeting of the Illinois State Medical Society will be held at Champaign-Urbana, May 18-20, under the presidency of Dr. Jacob C. Krafft, Chicago. The house of delegates meets Tuesday morning. David Kinley, LL.D., president, University of Illinois, will address the general session on that day on "Some Influences Affecting Medical Education." The oration in medicine will be delivered by Dr. William Engelbach, St. Louis, Wednesday evening; the oration in surgery by Dr. William D. Haggard, Nashville, Tenn., immediate past president of the American Medical Association, on "The Present Status of the Goiter Problem." Among other visiting speakers will be Dr. W. McKim Marriott, St. Louis, "Newer Knowledge Concerning Nephritis"; Dr. Arthur Steindler, Iowa City, "Treatment of Mediastinal Abscess Complicating Dorsal Pott's Disease"; Dr. Donald MacRae, Jr., Council Bluffs, Iowa, "Emergency Lung Surgery", and Frederick L. Hoffman, Ph.D., Newark, N. J., "The Cancer Outlook." An excellent program of entertainment has been arranged.

INDIANA

License Reinstated.—The license of Dr. William B. Hartsock, Indianapolis, which was revoked, April 17, 1924, was reinstated, Jan. 12, 1926, says the state board of medical registration. Dr. Hartsock served a term in prison at Atlanta for violation of the Harrison Narcotic Law.

Moving Pictures of Smallpox.—Since February 14, the film "One Scar or Many" has been shown in the Gary schools ninety-six times to 12,880 children, portraying the various stages of smallpox and how it can be prevented by vaccination. As a result, the state board of health says, the school physician has vaccinated 1,481 children since February 14, and had more than 200 requests which had not yet been done. Before the film was shown this year in school, that is, from Sept. 4, 1925, to February 14, the total number of vaccinations performed by school physicians was 691.

IOWA

Guests at State Meeting.—At the seventy-fifth annual session of the Iowa State Medical Society, Des Moines, May 12-14, the visiting speakers will be Drs. Olin West, Chicago, Albert R. Mitchell, Lincoln, Neb., William J. Mayo, Rochester, Minn., Allen B. Kanavel, Chicago, Max A. Goldstein, St. Louis, Charles A. Elliott and William Allen Pusey, both of Chicago, George E. Price, Spokane, Wash., Franklin P. Gengenbach, Denver, Paul D. White, Boston, and John B. Deaver, Philadelphia. Thursday evening will be "guests and past presidents' evening"; the president, Dr. Smith A. Spilman, will give his address, and the secretary, Dr. Tom. B. Throckmorton, will present the guests and past presidents; Dr. Walter L. Bierring's subject will be "A Diamond Jubilee" and that of Dr. Charles Ryan, "Reminiscences"; there will then be an award of prizes for the best story pertaining to medical experiences, for the oldest member present, and for the best antique medical and surgical exhibit. The annual banquet will be Wednesday evening at the Hotel Des Moines. The scientific program comprises clinical demonstrations and addresses by the guests and prominent physicians of the state. Luncheons at the Wakonda Club, a matinee and bridge party in addition to the banquet and past presidents' evening have been arranged for the ladies.

LOUISIANA

State Medical Election.—At the forty-seventh annual convention of the Louisiana State Medical Society, Monroe, April 17, Dr. Stephen M. B. Blackshear, New Orleans, was elected president, and Dr. Arthur A. Herold, Shreveport, president-elect; Drs. James A. White, Alexandria, Courtland P. Gray, Monroe, and Remy G. Ducote, Bordelonville, vice presidents, and Dr. Paul T. Talbot, secretary-treasurer. The next annual meeting will be held in New Orleans.

New Orleans Tuberculosis Clinics.—The New Orleans Antituberculosis League's clinics were attended during Februray by 1,011 persons, a new high record; 133 of these were new patients and of them twenty-two were found positive for tuberculosis, and thirty-seven were placed under observation. The league has three morning clinics under the direction of Dr. Julius M. Davidson, and four afternoon clinics under the direction of Dr. George S. Brown. It is now possible, says the *Times Picayune*, that any one in New Orleans can receive at these clinics an examination for tuberculosis by experts.

Hospital News.—The report of the superintendent of Charity Hospital, New Orleans, notes that the John Dibert Tuberculosis Hospital, which was constructed as an associated unit, will be maintained without cost to the state; a new unit of 120 beds to Charity Hospital, made possible by public subscription, was opened last December, and ninety beds are in order. The hospital needs more nurses and interns, for whom there are now insufficient housing facilities.——The first unit of the Southern Baptist Hospital, New Orleans, was opened for the reception of patients, March 8; it has a capacity of 218 beds; when complete, the hospital will have a capacity of 800.

MISSOURI

Hospital News.—The Missouri Conference of the Methodist Episcopal Church has made plans to raise $300,000 for the Missouri Methodist Hospital in St. Joseph, the campaign to extend over a period of three years, the churches of St. Joseph to raise $50,000 annually, and other churches in the conference outside the city to raise a like amount.——The Missouri Hospital Association will hold its annual meeting, May 17, in St. Louis.

Attorney General's Opinion.—Attorney General Gentry has given an opinion to the city counselor of St. Louis, stating that a physician not licensed in Missouri, although he had served in the U. S. Public Health Service, cannot act as hospital commissioner of the city of St. Louis or director of medical and tuberculosis dispensaries, without first being examined by the state board of health as to his qualifications and obtaining a license to practice. The ruling was made to establish the right of Dr. R. A. Gunter, head of the Veterans' Bureau at St. Louis, to accept the appointment of tuberculosis controller of that city. The opinion removes all doubt as to the right of a person to practice in Missouri even though his practice is limited to state, municipal or county service on a salary basis, without a license. Physicians in the service of the United States government are exempted by statute while they are serving in their official capacity.

NEW YORK

Civic Award to Dr. Birkhaug.—The Women's Educational and Industrial Union of Rochester has made its initial civic award to Dr. Konrad E. Birkhaug, associate in bacteriology, University of Rochester School of Medicine, for his "contribution to medical knowledge and relief of human suffering." The award of $500 and a diploma was made by the president of the university, Rush Rhees, and the address of the evening was by George Barton Cutten, president of Colgate University, whose subject was "Rewriting History." The award is given for the most "outstanding service for the best interests of Rochester during the year." Dr. Birkhaug's contribution is said to have been in connection with research on the cause and treatment of erysipelas.

Society News.—Dr. Marion Craig Potter, Rochester, has been elected president of the Women's Medical Society, New York; Drs. M. Louise Hurrell, Rochester, Adelaide Dutcher, Syracuse, and Edith R. Spaulding, New York, vice presidents; Dr. Anna Harvey Voorhis, Yonkers, secretary, and Dr. Harriet F. Coffin, New York, treasurer.——Dr. Lewis Gregory Cole presented an illustrated paper, "Cinema of the Lungs," before the Medical Society of the County of Kings, April 20, and Dr. Stuart Pritchard, Battle Creek, Mich., gave an address on "Differential Diagnosis of Thoracic Affections." The society recently gave a series of sixteen health talks and motion picture demonstrations in one of the large department stores, which was a feature of its educational program.——At the April 15 meeting of the Brooklyn Ophthalmological Society, three cases were presented of blindness following the use in pneumonia of some of the newer quinine derivatives.——Dr. Samuel Parnass has been elected president of the Brooklyn Urological Society; Dr. Albert Harris, vice president, and Dr. Abraham Ravich, secretary-treasurer.

New York City

Dr. Gay Appointed Visiting Professor.—Dr. Frederick P. Gay, professor of bacteriology, Columbia University College of Physicians and Surgeons, has accepted an appointment as visiting professor to Belgium under the auspices of the Committee for Relief in Belgium Educational Foundation. Dr. Gay will remain abroad during the next academic year, lecturing on immunity at the Belgian universities in Brussels, Ghent, Liège and Louvain.

Appointments at Columbia.—Columbia University announces the appointment of Dr. Benjamin P. Watson, of the University of Edinburgh, as head of the department of obstetrics and gynecology with the rank of full professor; also the appointment of Dr. Joseph G. Hopkins, New York, as professor and head of the department of dermatology and syphilology and Dr. George M. MacKee as professor of dermatology and syphilology. Dr. Watson was born in Scotland in 1880 and received the M.B. and Ch.B degrees at the University of Edinburgh, where he became lecturer in obstetrics and gynecology in 1905. He was called to Toronto as professor of obstetrics and gynecology in 1912, and was also obstetrician and gynecologist in the Toronto General Hospital; from there he was called to the chair at Edinburgh. Dr. Watson was recently the Buchannan scholar in gynecology at the University of Edinburgh and Freeland Barlow fellow at the Royal College of Edinburgh. He was elected fellow of the American Gynecological Society in 1915. Dr. Hopkins was born in Brooklyn in 1882 and received the M.D. degree from Johns Hopkins University Medical School in 1907; he served there a two-year internship, was two years resident physician at St. Luke's Hospital, and for years after was bacteriologist and assistant attending physician at the same place. He was made assistant professor in the Columbia Department of Bacteriology in 1915, was bacteriologist with the Red Cross Commission in Serbia, and in 1918-1919 was in the Medical Corps in charge of Base Laboratory no. 3 at Winchester, England; on returning, he became associated with the dermatology department at Columbia and for six years has been affiliated as associate in roentgenology with the Crocker Laboratory. Dr. MacKee was born in Jersey City in 1878 and received his M.D. degree from New York University and Bellevue Medical College in 1899. After postgraduate work he entered the service of the late Dr. John A. Fordyce in 1903, then transferred to the Columbia Medical School in 1911 as chief of clinic and instructor; was professor of roentgenology in the Angle School of Orthodentia from 1905 to 1907; editor of the *Journal of Cutaneous Diseases* from 1909 to 1920, and is now on the editorial board of the *Archives of Dermatology and Syphilology*, also consulting dermatologist and syphilologist at various hospitals, and lecturer on cutaneous tuberculosis at the Trudeau School of Tuberculosis, Saranac Lake.

Twenty-Six Dermatologists Resign.—The New York *Times*, April 18, states that twenty-six members of the staff of the department of dermatology, Columbia University College of Physicians and Surgeons and of the Vanderbilt Clinic, resigned within the last week. Among the reasons given was that in selecting a head of the department of dermatology to succeed the late Dr. John A. Fordyce, the faculty of the medical college did not choose the senior member of the department, but selected his assistant. There was said to be a feeling among members of the staff that the governing body had failed to appreciate the service of men of large clinical experience in the treatment of disease and had placed too much emphasis on laboratory work. Those who resigned, according to the *Times*, were:

George M. MacKee
Fred Wise
Isadore Rosen
Joseph J. Eller
Elizabeth C. Jagle
Max Scheer
Elias W. Abramowitz
David Bloom
Harry C. Saunders
David Ballin
David L. Satenstein
Charles Lerner
Samuel Strumwasser
Myles Standish
Edwin D. Newman
Bernard B. Berkowitz
H. Norton
Frederick Amshel
Louis F. X. Wilhelm
Lotta W. Myers
Josiah P. Thornley
Samuel J. Littenberg
John H. Harris
Van Alstyne H. Cornell
Louis Tulipan
John Remer

OHIO

Society News.—Dr. Willard C. Stoner, director of medicine, St. Luke's Hospital, Cleveland, addressed the Hancock Medical Society, Findlay, April 7, on "The Problem of the Subacutely and Chronically Ill."

Chiropractors in Court.—The Ohio State Medical Board reports that the following chiropractors were recently convicted of practicing without a license:

H. S. Heimbaugh, Painesville, $25 and costs.
A. P. Jacobson, Fairport Harbor, $25 and costs.
L. S. Williams, of Grand Rapids, was convicted at Bowling Green.
Paul O. Mende, Ironton, $75 and costs.

Hospital News.—The Oxford Retreat, Oxford, has sold its main building and a portion of the ground to Miami University, and during the past year has been constructing a new modern, fire-proof stone building, which was opened, about April 15, for the use of mild mental cases.——The new Starling-Loving University Hospital, Columbus, has been in operation for about six weeks.——The Ohio Hospital Association and the Ohio Dietetic Association held their annual convention in Columbus, March 31-April 1; among the speakers at the annual dinner were Dr. Arthur C. Bachmeyer, Cincinnati; Dr. William H. Walsh, Chicago; Dr. Thomas A. Ratliff, Cincinnati; Dr. Clarence L. Hyde, Akron, and Dr. Edson J. Emerick, Columbus.——A dinner was given, March 11, at the Charity Hospital, Cleveland, in honor of Dr. Frank E. Bunts to commemorate his forty years' service to that institution; about 175 physicians were in attendance, and among the speakers were Dr. Thomas A. Burke, Dr. Carl A. Hamann, Dr. Joseph E. Cook, and Bishop Joseph Schrembs.——The Charity Hospital is conducting a campaign for $1,500,000 for remodeling and enlarging the hospital.

OKLAHOMA

Change of Date of Meeting.—The Oklahoma State Medical Association has changed the date of the next annual meeting to June 22-24, 1926. The reason given in the journal of the association is that the president and other men prominent in the association had been assigned to temporary military duty during the original date set for the meeting in May.

Revocation of License Sustained.—The Supreme Court of Oklahoma upheld the action of the Pottawatomie Superior Court in dismissing the application of Dr. Paul P. Oliver, Shawnee, for a writ of certiorari in connection with the revocation of his license to practice by the state board of medical examiners, after having been found guilty of unprofessional conduct.

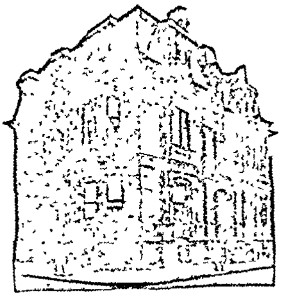
PENNSYLVANIA

Fifty Years in Practice.—Patients and friends of Dr. James M. Hamilton, Oakmont, a suburb of Pittsburgh, recently presented him with a new motor car on his completion of fifty years in practice in that community; in the near future the chamber of commerce will celebrate the occasion by the observance of "Hamilton night."

State Health Department Items.—The state department of health will conduct an exhibition at the Sesqui-Centennial in Philadelphia, which will show the progress in public health work in Pennsylvania in the last century; it will be in the left wing of the Pennsylvania Building.——A recent typhoid epidemic at Glenshaw, near Pittsburgh, was found to be due to a well polluted by seepage from a nearby cesspool.——Cumberland County has just formed a public health association and elected Dr. Henry C. Lawton, Camp Hill, president; a number of counties in the state have such organizations, the purpose of which is to correlate the work of the county units, state department of health and the state association.——There was an outbreak of smallpox recently at St. Mary's Monastery and St. Fidelis College, Herman, Butler County; three of the eight patients were priests and all of them had either never been vaccinated or had been vaccinated unsuccessfully. During the recent severe outbreaks of measles in various parts of Pennsylvania, the state department of health issued instructions concerning control, in which it disapproved the closing of schools to control outbreaks of measles or other contagious diseases. It was urged that daily inspections be made of all school children in search for early symptoms of disease, and that when a case is discovered in a classroom, the daily examination should be maintained for two weeks to discover other cases that might develop from the first exposure.——The death rate for diphtheria in the state recently has been the lowest ever experienced, representing a 50 per cent reduction since diphtheria immunization was begun by the state department of health in 1921.

Philadelphia

Society Dedicates New Home.—The Philadelphia County Medical Society dedicated its new home at Twenty-First and Spruce streets, April 20 and 21, with appropriate ceremony. Dr. Isidor P. Strittmatter, chairman of the building committee, presented the deed and keys of the building to Dr. Moses Behrend, president of the society, who made the principal address; among the other speakers were Drs. William W. Keen, Arthur C. Morgan and Hobart A. Hare, representatives of the chamber of commerce, the common pleas court, the law association, and the board of trustees of Jefferson Medical College. There was a housewarming Wednesday night with a musical program and dancing. The *Weekly Roster and Medical Digest*, April 17, celebrates the opening of this society home with reproductions of photographs of members prominent in the construction and dedication of the building.



SOUTH CAROLINA

State Medical Election.—At the seventy-eighth annual meeting of the South Carolina Medical Association, Sumter, April 6, Dr. George H. Bunch, Columbia, was elected president; Drs. William C. Black, Greenville, Charles J. Lemmon, Sumter, and William L. Pressley, Abbeville, vice presidents, and Dr. Edgar A. Hines, Seneca, secretary-treasurer, reelected. The next annual meeting will be held in Anderson, April, 1927.

TENNESSEE

Society News.—The Memphis and Shelby County Medical Society will celebrate its fiftieth anniversary, May 13, at the University Club; a nonscientific program and a banquet have been arranged.

Personal.—Dr. Barney Brooks, professor of surgery, Vanderbilt University School of Medicine, Nashville, addressed the Cincinnati, Ohio, Academy of Medicine, April 5, on "Diseases of the Circulation of the Extremities."

Hospital News.—The board of trustees of the Baptist Memorial Hospital, Memphis, will erect a nine story annex to the present building on Madison Avenue. The *Memphis Medical Journal* says that commercial shops and branch banks will be allowed space in the building.

University News.—Dr. James M. Skinner, Jr., McMechen, W. Va., Dr. Morton J. Tendler, New Haven, Conn., and Dr. James W. McElroy, Memphis, have been appointed resident surgeon and instructor in surgery, resident physician and instructor in medicine, and resident pathologist and instructor in pathology, respectively, at the University of Tennessee School of Medicine and the Memphis General Hospital.

TEXAS

Chiropractors Lose Appeal.—The U. S. Circuit Court of Appeals at New Orleans refused to grant an injunction, April 16, petitioned for by chiropractors of Texas, it is reported, to restrain the attorney general and others in the state from arresting them for practicing without a license as provided for in the Texas medical law of 1907.

State Medical Meeting.—The sixtieth annual session of the State Medical Association of Texas will be in Houston, May 25-27, under the presidency of Dr. Charles M. Rosser, Dallas, with headquarters at the Municipal Auditorium. There will be a luncheon daily at the Rice Hotel, addressed by prominent physicians. Dr. William Seaman Bainbridge will address a public session, Wednesday, on "Recent Investigations Into the Cause of Cancer and the Outlook for Prevention and Treatment," and the section on surgery on "Gastro-Intestinal Diverticula." The alumni banquet will be Tuesday evening, May 25, following the memorial exercises. In addition to prominent state physicians who will address the sections, Dr. William Engelbach, St. Louis, will speak on "Hair Growth and Pigmentation Related to Endocrine Disorders." The Texas Radiological Society and the Texas Federation for Health Education will hold their meetings during the session; also the Texas Railway Surgical and Hygienical Association.

VIRGINIA

State Board Election.—Dr. William T. Graham, Richmond, was elected president of the state board of health at the April 1 meeting, to succeed the late Dr. William M. Smith; Guy R. Harrison, D.D.S., Richmond, was elected vice president, and Dr. Lawrence T. Royster, University, secretary.

Personal.—Dr. Estridge P. White, Odd, has been elected president of the First National Bank of Poquoson.——Dr. Sidney L. Scott has been elected president of the chamber of commerce of Fredericksburg.——Dr. Louis E. Fuller, Callands, has been appointed a member of the school board of Pittsylvania.——Dr. and Mrs. William T. McLemore, Courtland, celebrated their silver wedding anniversary, April 3.

Hospital News.—The proposed hospital for crippled children to be erected in Richmond by the Shriners will be on a site of about 9 acres, recently purchased, on Grove Avenue west of the belt line.——The $60,000 required to be raised for a hospital by the community of Farmville, for which the Commonwealth Fund will give $120,000, was almost all subscribed at last accounts, and it was expected that the contract for the hospital would be let in April.——At the celebration of the twentieth anniversary of the Elizabeth Buxton Hospital, Newport News, February 23, the staff presented a memorial tablet of the late Dr. Edwin M. Newsom.——A twenty-four room building is being added to the Seaside Cottage Sanatorium at Virginia Beach which will open, June 1, under the supervision of Drs. William L. Harris and Claiborne Willcox. The resident physician will be Dr. Cora Z. Corpening.

WEST VIRGINIA

Miscellaneous Items.—The West Virginia Medical Association will hold its annual meeting at Morgantown, May 25-27.——There were about twenty deaths in the state in January and February due to measles; about 983 cases were reported in February, twice the number reported in January.

WISCONSIN

Society News.—Dr. Harry Gideon Wells, Chicago, addressed the Medical Society of Milwaukee County, Milwaukee, April 9, on "The Influence of Heredity on the Occurrence of Cancer in Man."

Milwaukee's Health Report.—The general death rate in Milwaukee in 1925 was 10.6, and the infant mortality 77; both slight increases over 1924, but lower than the average for the last five years. There was a smallpox epidemic in 1925 in which eighty-seven people died; there were 381 cases of acute alcoholism admitted to hospital, as compared to 376 the year before. Pneumonia caused 717 deaths, or 196 more than the year before; heart disease came second, with an increase over the preceding year; then cancer, cerebral hemorrhage, nephritis and pulmonary tuberculosis. There were 336 prosecutions for violations of laws which protect the public health. Among the ordinances passed in 1925 was one which requires eating places to serve milk in the original bottles, and one requiring all food venders to obtain a license from the health department. There were fewer deaths from typhoid and scarlet fever; 12,229 treatments with toxin-antitoxin for the prevention of diphtheria were given. The bacteriologic laboratory made more than 53,000 examinations, and the nurses of the health department made more than 300,000 inspections of children in the schools for contagious disease.

GENERAL

Sex Differences in Mental Traits.—An extensive bibliography of "Sex Differences in Mental Traits," prepared by C. M. Louttit of Yale University, New Haven, Conn., is reprinted in the April number of *Welfare Magazine*, published by the department of public welfare of the state of Illinois at Springfield.

National Hospital Day.—May 12 has been set aside as National Hospital Day in order to make people better acquainted with hospitals. There is to be no solicitation or drive. The American Hospital Association will issue a certificate of award to be given to that hospital whose hospital day program is considered most meritorious; hospitals are requested to send to the association details of their program and other material which indicate how effective it was.

Committee Favors Retired Pay for Nurses.—There has been favorably reported from the Senate Committee on Military Affairs a bill providing for retirement pay for army and navy nurses. The bill has the approval of Secretary of War Dwight F. Davis and was endorsed also by his predecessor, Secretary J. W. Weeks; it recognizes the fact that nurses are an integral part of the military establishment and that they should have the same privileges with respect to retirement pay as are now awarded to regular army and navy officers after a definite period of service.

Delegation to Study Trachoma Among the Indians.—The New York *Times*, April 25, notes that a delegation of ophthalmologists and others left the previous day to inspect Indian reservations in Oklahoma in an effort to check trachoma. The delegation includes Dr. Benjamin Franklin Royer, medical director, National Committee for the Prevention of Blindness; Dr. Arthur M. Yudkin, Yale University School of Medicine, New Haven, Conn.; Dr. William H. Wilder, Chicago; and Dr. Thomas B. Holloway, University of Pennsylvania School of Medicine.

Pan-American Health Conference.—Surg. Gen. Hugh S. Cumming, U. S. Public Health Service, has issued invitations to health officers in the twenty-one countries which comprise the Pan-American Health Conference, for a meeting in Washington, D. C., September 27-29, when problems of health administration and disease control will be discussed. It is expected that one or more health officers from each country will be present and remain to attend the meeting of the International Union Against Tuberculosis, which will be held in Washington, September 30-October 2.

Society News.—Dr. William H. Kiger, Los Angeles, has been elected president of the American Proctologic Society for the ensuing year; Dr. George W. Combs, Indianapolis, vice president, and Dr. Louis A. Buie, Mayo Clinic, Rochester, Minn., secretary-treasurer.——At the annual meeting of the New England Dermatological Society, April 14, Dr. Charles Morton Smith, Boston, was elected president, and Dr. Walter T. Garfield, 19 Bay State Road, Boston, secretary.——At the annual meeting of the Medical Women's National Association, Dallas, Texas, April 18-19, Dr. Frances E. Rose, Spokane, Wash., was elected president; Dr. Elizabeth B. Thelberg Poughkeepsie, N. Y., president-elect; Dr. Ethel Doty Brown, treasurer, and Dr. Maud Parker, Seattle, secretary.

Sight Saving Classes.—The managing director of the National Committee for the Prevention of Blindness announces that a course for training teachers for sight saving classes will open, June 21, at the University of Cincinnati and continue for six weeks. Full credit will be given by the university for this work. Applications for registration have been received from a number of states. The work includes: theories and methods of supervision and organization of sight saving classes; theories and methods of teaching sight saving classes, and courses in elementary and advanced eye work. There are said to be in the United States 242 sight saving classes, which is far below the number needed to educate properly children who have seriously defective vision and who therefore need special educational facilities. A lack of teachers is said to be the principal difficulty in the way of establishing more sight saving classes.

International First-Aid Contest.—Under the auspices of the U. S. Bureau of Mines, the fifth International First Aid and Mine Rescue Contest will be held in the Civic Auditorium, San Francisco, and the Greek Theater of the University of California, Berkeley, during the first week of September. The object of this annual event is to train miners in first aid and rescue methods in order to advance the cause of safety among miners. The contest in first aid and mine rescue will be for international championships; cups, medals and prizes will be awarded to the winners. A feature of the meeting will be the award of the Congressional Medal, which is given to the team of miners most thoroughly skilled in first aid and mine rescue methods. Judges thoroughly familiar with this work will make the awards in accordance with standards of the bureau of mines. All organizations interested in the contest are invited to enter first aid and mine rescue teams. Entry blanks and other information can be obtained from the Experiment Station, Bureau of Mines, 4800 Forbes Street, Pittsburgh.

American Society for the Control of Cancer.—At the business meeting in March in New York of the American Society for the Control of Cancer, the managing director, George A. Soper, Ph.D., reported that he had spent three months in Europe interviewing about fifty eminent students of cancer and seeing cancer clinics and hospitals, and had made arrangements for a visit to this country in September of distinguished cancer specialists. The society is now endeavoring to increase its endowment to at least $1,000,000. Mr. John D. Rockefeller, Jr., has just contributed $125,000 toward the expense of the society's work, and made an additional offer of $10,000 toward the expense of the meeting of specialists to be held in September. The field secretary of the society in the last year addressed medical and lay audiences in every state except two, and collected information about the society's work throughout the country. Preparations have been made to conduct an educational campaign throughout the country in the immediate future with "ammunition" of a more effective character than has been used heretofore; this campaign will not be of the "cancer week" variety, but of a longer and less intensive character. The results of this work will depend largely on the state cancer organization; an Eastern state is perfecting an elaborate organization to promote a three year campaign of exceptional thoroughness.

Bequests and Donations.—The following bequests and donations have been announced recently:

St. Luke's Hospital, Davenport, Iowa, $10,000, and the Visiting Nurses Association, Davenport, $1,000, by the will of the late Mrs. Susan C. Francis, Davenport.

The Mount Sinai Hospital, $10,000, by the will of the late Rosa Hochstader.

The Presbyterian Hospital, Charlotte, N. C., $15,000, by the will of the late Mrs. W. S. Alexander.

The will of the late J. Adolph Mollenhauer of Brooklyn provides bequests of $5,000 each to the Lutheran Hospital Association, New York; the South Side Hospital, Bay Shore, L. I.; the Industrial Home for the Blind, New York, and the Visiting Nurses Association, New York, and $10,000 to the House of St. Giles the Cripple, New York.

The Samaritan Hospital and Temple University, each $1,500, by the will of the late Mary J. Mabie.

Pennsylvania Hospital, Philadelphia, $1,000, and the Federation of Jewish Charities, $4,000, by the will of the late Louis Kohn.

The Presbyterian Hospital, Philadelphia, $5,000 to endow a free bed, by the will of the late Sarah I. Alvord.

The St. Luke's Hospital, New Bedford, Mass., $25,000; the Association for the Relief of Aged Women, New Bedford, $10,000; Yale University, New Haven, Conn., $100,000, by the will of the late William W. Crapo of New Bedford.

The Memorial Hospital, New York, $25,000, by the will of the late James Jackson Storrow of Boston.

St. Luke's Hospital of Newburgh, N. Y., $5,000, by the will of Jessie M. Gibson of Yonkers.

The Huntington Hospital, Huntington, L. I., $10,000, by the will of the late Mrs. Emma Hewlett.

The Brooklyn Home for the Blind, Crippled and Defective Children, St. Peter's Hospital, Holy Family Hospital, Little Sisters of the Poor and the Nursing Sisters of the Sick Poor, Brooklyn, each $500, by the will of Catherine Donigan.

The Philadelphia Home for Incurables, $15,000, to endow free beds in memory of her parents; the Presbyterian Hospital, Philadelphia, $10,000, to endow beds in memory of her brothers, and the Home of the Merciful Saviour for Crippled Children and the Children's Seashore House, Atlantic City, $5,000 each, by the will of the late Jennie Forrest.

The Home for Old Men and Aged Couples, New York, $17,000, and the New York Association for the Blind, $2,632, by the will of Cora C. Withers.

The Michael Reese Hospital, Chicago, $600,000, by the will of the late Henry L. Frank.

The St. Rose Home for Cancer, New York, $1,000, by the will of Bertha French.

The Home and Hospital, Findlay, Ohio, $12,000, by the will of Maretta Lenhart.

The Union Hospital, Terre Haute, Ind., $40,000, by the will of Martin A. Sheets.

Dr. Carl A. Grote has donated $10,000 to the Huntsville Hospital, Huntsville, Ala., as a memorial to his father.

The Addison Gilbert Hospital, Gloucester, Mass., $15,000, by the will of Lucy Brown Davis, for the support of a room to be named in honor of the donor.

The Bryn Mawr Hospital, Bryn Mawr, Pa., $100,000, by the will of John Howard Supplee of Rosemont, as a memorial to his son.

The Jewish Sheltering Home and the Jewish Home for the A
Rochester, N. Y., each $500 by the will of Augusta Black.

The Beth Israel Hospital, New York, $250, by the will of the late Simon Abrons.

The Women's Hospital, New York, $300,000, by the will of the late Mrs. Mary Clark Thompson.

The State Charities Aid Society of New York, $500,000, and the Charity Organization Society of the City of New York, $25,000, by the will of the late Mrs. Anna M. Richardson Harkness.

Roosevelt Hospital, New York, $100,000, by the will of the late Mrs. Mary E. Jesup, as a memorial to her husband, and with the proviso that only the income of the fund be used by the hospital.

The Jewish Hospital, Brooklyn, $1,000, by the will of Monday Esther.

The New York Society for the Prevention of Tuberculosis and the Jewish Hospital for Consumptives, Denver, $1,000 each; the Trudeau Sanatorium, Trudeau, N. Y., Saranac Lake, and the Society for the Prevention of Tuberculosis, Saranac, N. Y., $500 each, by the will of Harry E. Schwarz.

PORTO RICO

Dr. Hill Goes to Venezuela.—After six years of public health work in Porto Rico in connection with the Rockefeller Foundation, Dr. Rolla B. Hill has been selected to represent that organization in Venezuela in the same capacity; he sailed for New York, March 11, after having been the guest of honor at a luncheon tendered by the commissioner of health of the island. Dr. Hill came to Porto Rico in 1920 to cooperate with the department of health in a campaign against the hookworm, and since July, 1925, has been medical adviser to the bureau of rural sanitation, in which office he will be succeeded by Dr. Florence A. K. Payne of the International Health Board.

FOREIGN

International Union Against the Venereal Peril.—The first number of the *Bulletin* issued by the *Union Internationale contre le Péril Vénérien* gives the history of the society and its aims. Thirty-four countries are officially represented in the union.

Success of Antityphoid Vaccination.—The recent extensive inundations in the lower Rhine region caused much alarm from fear of typhoid, but our Belgian exchanges state that quantities of antityphoid vaccine were donated and used in the flooded regions in Belgium, and the danger of an epidemic was averted.

Italy Bars Birth Control.—A cable dispatch notes that the minister of the interior of Italy has installed a committee to protect the families of that country against "insidious, practical, pseudoscientific neomalthusian propaganda." The minister is reported to have said that Italy is now seriously affected by birth control propaganda and that it has been decided to protect the family by decreasing infant mortality and conquering "egotistic birth control propaganda."

New Medical Journal.—The first number, that of January, of the *Malayan Medical Journal and Estate Sanitation* has been received. It is said to be the only medical journal published in Malaya, and will publish material peculiar to that region. The editors are Drs. T. S. Macaulay, G. B. McHutchison, J. J. Hicky and W. Thunder. It is to be a quarterly record of medicine and surgery, with especial reference to tropical medicine and estate health.

Personal.—Dr. C. Baastrup, the radiologist of the Bispebjærg Hospital, Copenhagen, has been elected a member of the French Société de radiologie médicale.——Dr. C. van Veen, Helmersstraat 206, Amsterdam, was the secretary of the first Netherlands pedagogic congress which met at Amsterdam April 8.——Dr. Duchateau was the representative of the government at the exposition of the work of women at the family placement colony at Gheel. For centuries Gheel has been an important element in the care of the docile insane in Belgium. The wives of the five local physicians have recently been encouraging the women in handiwork, and the results have been excellent from the therapeutic as well as the artistic standpoint, according to the *Scalpel* of Brussels.——Dr. J. Leclercq delivered an address on "The Time Required for Nerve Impulses During Work" at the recent inauguration of the university Institut des sciences sociales at Lille.——Dr. Carteado Mena, Oporto, has had to have part of his right hand amputated on account of professional roentgen-ray injuries, the first victim of the kind in Portugal.——The Engadine region has been celebrating the twenty-fifth anniversary of the introduction of heliotherapy into scientific medicine by Dr. Oskar Bernhard, who has practiced in the Engadine for forty years. As a final, desperate resort in a case of a grave wound which had absolutely refused to heal, he recalled the sterilized and shriveled condition of sundried thin strips of beef, the charqui or jerked beef of South America.

Government Services

Appointments and Resignations in Veterans' Bureau

The April issue of the U. S. Veterans' Bureau *Medical Bulletin* notes the following appointments and resignations of physicians in the Veterans' Bureau at the hospital indicated:

Dr. E. L. Hunt appointed pathologist, Hospital 89, Dec. 1, 1925.
Dr. Herman Judd, resigned at Hospital 98, Dec. 31, 1925.
Dr. Harold T. Nesbit, resigned at Hospital 65, Feb. 28, 1926.
Dr. Ambler B. Patton, resigned at Hospital 60, Dec. 4, 1925.
Dr. Waldermar G. Richter, appointed at Hospital 86, Dec. 1, 1925.
Dr. Wilmarth Y. Seymour, appointed at Hospital 62, Dec. 16, 1925.
Dr. George S. Silliman, appointed at Hospital 103, Dec. 28, 1925.
Dr. James A. Smart, appointed at Hospital 88, Jan. 21, 1926.
Dr. Hyman D. Shapiro, resigned at Chicago (Central Board of Appeals, Area D), Jan. 14, 1926.
Dr. Benjamin A. S. Stephenson, resigned at Hospital 69, Feb. 17, 1926.
Dr. Henry O. Witten, resigned at Hospital 42, Jan. 10, 1926.

U. S. Public Health Service

Surg. Marshall C. Guthrie was relieved from duty as executive officer of the bureau, Washington, D. C., March 26, and directed to report to the Secretary of the Interior for duty in connection with the Indian Medical Service.——Acting Asst. Surg. Gordon B. Carr was directed, March 27, to proceed from Sturgis, Ky., to Chicago for duty in Marine Hospital no. 5.——Surg. Joseph Goldberg was directed to proceed from Washington, D. C., to New York, March 29, and return in connection with pellagra studies.——P. A. Surg. Kenneth F. Maxcy will be relieved from duty at Montgomery, Ala., May 1, when he will report to the director of the hygienic laboratory, Washington, D. C., for duty. Drs. Marion F. Haralson and John F. Mahoney have been promoted and commissioned in the grade of surgeon, effective March 18, 1926.——Lieut. M. Rogers has been promoted and commissioned in the grade of passed assistant surgeon, U. S. Public Health Service, effective, April 5.

Navy Orders

Lieut. Comdr. Reynolds Hayden has been ordered to the naval training station, Hampton Roads, Va., for duty; Lieut. Waldo E. Golden to the naval hospital, Great Lakes, Ill.; Lieut. Comdr. Fenimore S. Johnson to the naval hospital, New York; Lieut. James Humbert to the recruit barracks, Hampton Roads, Va.; Lieut. Comdr. Horace V. Cornett to the naval hospital, League Island, Philadelphia; Lieut. Comdr. Harry R. Hermesch to the navy yard, Washington, D. C.; Lieut. Francis E. Tierney to the naval air station, San Diego, Calif.; Lieut. George W. Wilson to the naval hospital, Puget Sound, Wash., and Lieuts. Charles R. Tatum and Arthur S. Judy to Port au Prince, Haiti.

Summer Camps for Reserve Officers

Surgeon General Merritte W. Ireland, announces that the medical department of the army will maintain camps this summer for the military training of physicians who have commissions in the medical reserve corps. The war department has selected four camps for training physicians at Carlisle Barracks, Pa.; Fort Snelling, Minn.; Fitzsimons General Hospital, Denver, Colo., and Camp Lewis, Washington. Officers of the various sections of the medical reserve corps, who can accept training, will have the advantage of full field instruction, including tactics and technic of operation of divisional medical units. Troops will be available to demonstrate the operation of these units. It is proposed to make the training intimate and practical, presenting to reserve officers the opportunity to exercise command and execute plans simulating actual conditions that will prevail when they are called in emergencies. The training is for a period of two weeks at each camp during June and July, respectively. The camps open June 13 and close June 27 at Fort Snelling and Camp Lewis, and open June 16 and close June 30 at Carlisle Barracks, Pa. The camps for the month of July open July 4 and close July 18. Members of the medical reserve corps who desire to attend camp should apply to the commanding general of the corps area in which they reside. Transportation is paid to and from the camps, and reserve officers receive the same pay and allowances granted to regular army officers of like grade. A limited number of reserve officers can be accommodated at the camps; medical reserve officers are urged, therefore, to mail their applications promptly to the commanders of the corps area in which they reside.

Government Bill to Prevent Lead Poisoning

The text has been issued of the lead paint (protection against poisoning) bill, introduced by the government to make better provision for the protection against lead poisoning of persons employed in painting buildings. The home secretary is given power to make regulations: (*a*) for prohibiting the use of any lead compound except in the form of paste or of paint ready for use; (*b*) for the prevention of danger arising from the application of lead paint in the form of spray; (*c*) for the prevention so far as practicable of danger arising from dust caused by dry rubbing down and scraping; (*d*) for providing for the medical examination of persons employed in or in connection with painting with lead paint, and for the suspension from such employment of persons whose health is or appears likely to be injuriously affected thereby; (*e*) for securing facilities for washing during, and on cessation of, work to persons employed in painting; (*f*) for the use of protective clothing by persons so employed and for preventing clothes left off during work from being soiled by paint, and (*g*) for the distribution to persons so employed of instructions with regard to hygienic precautions to be taken. Clause 2 prohibits, after Nov. 19, 1927, the employment of women and young persons in painting buildings with lead paint, with the exception of apprentices in the painting trade under approved arrangements, and women or young persons engaged in decorative or other work excluded from the provisions of this section by an order of the secretary of state. Another clause gives power to an inspector under the factory and workshops act to take samples.

The Apologia of the General Medical Council

The press campaign against the general medical council because of its removal from the register of physicians guilty of trying to obtain patients by articles in the lay press, or of "covering" unqualified practitioners, has been described in previous letters. As much misconception exists, among not only the public but also the medical profession with regard to its functions, the council has issued a long memorandum on its constitution and functions. The council was created nearly seventy years ago by parliament, not with the purpose of promoting the welfare of professional men or professional corporations or of putting down quackery or even advancing medical science. The object was simply to protect the public. The preamble of the act of 1858 consists of two lines: "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners, Be it therefore enacted. . . ." Up to that time no easily understood line was drawn between the "qualified" and the "unqualified," and when the public desired to make a choice it was frequently at a loss. The act set up machinery for, as it were, "hallmarking" the qualified practitioner, so that he might easily be recognized. But the public was left free then, as it is free now, to seek "medical aid" from the unqualified practitioner. And the unqualified practitioner was left free then, as he is free now, to practice for gain among those who choose to employ and pay him. He was forbidden, under penalties, to pretend that he was qualified, by taking a title he did not possess; he might not use the courts for the recovery of his charges; he could not give a valid certificate of sickness or death; and now by the regulations made under the dangerous drugs act he cannot prescribe certain dangerous drugs, such as cocaine or morphine; but except for these and a few other not very inconvenient disabilities, he was untouched by the law. On the other hand, the "qualified" men, as a setoff to their new legal status and official recognition, were subjected to a new central control, educational and disciplinary. They obtained no monopoly of practice among the public in general. They were afforded no especial "protection" against the competition, not always scrupulous or insignificant, of the uncontrolled unqualified practitioner. The qualified practitioners might fairly have claimed that it would be good for the public, as well as for themselves, if monopoly of practice and protection against the competition of the untrained had been conferred on them. In other countries, and in other parts of the dominions, the restriction of practice to the qualified is with general consent and approval enforced by law. There, any unqualified person who habitually and for gain practices or holds himself out as practicing any branch of medicine or surgery is liable to severe penalties. In this country, indeed, the practice of dentistry and the practice of midwifery have been by law restricted to qualified persons. But in these days it requires some resolute ignoring of the signs of the times to believe that, in this free country, legislation restricting the practice of medicine and surgery to qualified persons only is either probable or possible in the near future. In one significant respect, however, the council is empowered to "protect" the aspirant to qualification—not against the competition of the unqualified, but against the possible action of the licensing bodies imposing on any candidate an obligation to adopt or refrain from adopting the practice of any particular theory of medicine or surgery, as a test or condition. Once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes. Indeed, at present some qualified practitioners are engaged without any hindrance in such crank practices as osteopathy and the use of the Abrams diagnostic box.

An Inquiry into Osteopathy

In a letter to the *Times*, Sir Montague Cotterill, a surgeon, points out that there are a certain number of duly registered physicians in this country who, in addition to their ordinary medical qualifications, have taken an opportunity of becoming conversant with the methods and the practice of osteopathy. It is said that these men have thus cured or relieved certain ailments that had failed to be successfully treated by the ordinary methods in vogue in medical practice. Before coming to the conclusion that these cures have been really due to some special osteopathic treatment, one must carefully bear in mind that, contrary to the general public opinion, the medical profession is fully aware of and sets a great value on the curative potentialities of what is commonly called "suggestion," which it prefers to describe as "possessing the confidence of the patient," with all that that entails. To what extent, then, does "suggestion" play a part in the reputed successess of osteopathy? In ordinary medical life any man fortunate enough (as Lister and others have been) to make a discovery, or become possessed of knowledge in any sphere of the healing art which we deem would be of service to the medical world in its important services to the public he would consider it not only imperative but also his greatest pleasure and privilege to impart his knowledge immediately, in all its details, to his medical brethren. One would have thought that the osteopathic registered physicians in this country would in like manner have taken every opportunity of imparting in the fullest way, and at the earliest moment, the details of the special lines of osteopathic treatment which they claim to be of such extraordinary value. But no offer of this kind has been made.

Sir Montague Cotterill suggests that there be appointed a committee consisting of authorities in anatomy, physiology, pathology, medicine and surgery. After an exhaustive investigation of all the matters concerned (and this could not be done except by a visit, extending over several weeks, to the chief school of osteopathy in America), these men would give a report, which would be accepted by the profession.

Physician Fined for Breach of Dangerous Drugs Regulations

At the mansion house before the lord mayor, a physician was summoned for having failed to comply with the provisions of the dangerous drugs act, in that, having supplied quantities of morphine to a person unknown, he did not enter or cause to be entered in a register kept for the purpose all dealings in that drug effected by him in the form and containing the particulars required; namely, did not enter the name or address of the person to whom the drug was supplied by him, and, being a qualified medical practitioner, did not record in a day book the name and address of the patient to whom the drug was supplied by him contrary to the dangerous drugs act. The prosecuting attorney said that this charge conveyed not the slightest reflection on the personal honor of the defendant. It was at the same time a matter of some importance because it was the policy of the home office to insist on the absolute compliance by every physician with the dangerous drugs act. A physician who supplied morphine to any of his patients must either keep a register in the form provided by the act, which must show the name and address of the patient to whom the morphine was given, or he must keep a day book in lieu of the register, which must also contain the name and address of the patient. The sole point in this case was that the physician declined to disclose either in the record under the schedule of the act or in the day book the name and address of the patient for whom he stated that he had been for more than twelve months in the habit of procuring from a pharmacist weekly a regular supply of morphine. Interviewed by a health officer of the ministry of health, he said that he did not now carry on a general practice, but he said that some of his old patients in the North of England had moved to London, and he saw them in a friendly way. Two of them, he said, were morphine addicts, and had asked him to treat them. One of them, a woman, he had succeeded in curing, and the other, a man, was improving as a result of his treatment. Another health officer called on the defendant, who said that his patient was 70 years of age and was improving. He declined to give the name and address of the patient. He did not consider that he ought to disclose the identity of the patient, who was struggling to be free from the necessity of taking drugs. The lord mayor said he had come to the conclusion that there had been a breach of the regulation, but, as in all probability this was a test case, he would impose only a nominal penalty of $125, with $50 costs.

Committee on Vaccination

The minister of health, in conjunction with the medical research council, has appointed a committee to inquire into and report on (1) matters relating to the preparation, testing and standardization of vaccine lymph; (2) the practical methods available in the light of modern knowledge to diminish or remove any risks that may result from vaccination, and (3) the methods of vaccination most appropriate for protection against the risk of smallpox infection in epidemic and nonepidemic periods; and to coordinate the work of investigation of these questions in this country and abroad, having regard to corresponding work undertaken by international health organizations. The committee consists of Sir Humphry Rolleston, president of the Royal College of Physicians (chairman), Dr. Mervyn H. Gordon, and others.

BELGIUM

(From Our Regular Correspondent)

March 6, 1926.

Radium Therapy in Cancer of the Cervix Uteri

Addressing the Société belge de chirurgie, Dr. Delporte summed up his opinion on treatment of cancer of the cervix as follows: "The Wertheim operation was the first step toward the proper treatment of cancer of the cervix. Irradiation constitutes the second stage. Today radium therapy should replace surgery." With respect to the Wertheim operation, he states that (1) 43 per cent of the cases are operable, while 60 per cent of the cases are abandoned; (2) there are difficulties of technic; (3) the operative mortality is from 10 to 15 per cent; (4) cure of operable cases, after five years, results in from 30 to 45 per cent, and (5) 60 per cent of the inoperable cases are abandoned. From the standpoint of radium therapy, however, he observes that (1) all cases are treated; (2) there is no technical difficulty; (3) there is no primary mortality; (4) cure of operable cases, after five years, results in from 30 to 40 per cent, and (5) cure of inoperable cases, after five years, in from 10 to 14 per cent.

Deep Irradiation with Gamma-Rays

Before the Société belge de gynécologie and the Société de physiothérapie, Dr. Sluys recently exhibited new radium applicators that obviate irradiating the skin unnecessarily. The radium is enclosed in lead capsules, thus restricting the direct cone of rays and absorbing the lateral rays that cause the surface tissues to receive a useless overdosage. This method makes it possible by means of crossfire irradiation to apply to the deeper tissues a summation of fairly large doses of radium without injuring the skin unduly, owing to the fact that the portals of entry do not overlap. The increased distance of the tubes requires considerable doses of radium. The appliance is adjustable to the region to be irradiated and the position of the patient. It is attached to an *appareil moulé* which arrests the secondary rays, aids in localizing the region to be irradiated, and makes it possible to measure the amount of irradiation.

Lingual Neuritis

Dr. Polus has communicated to the Société belge de stomatologie several cases of pain in the back and tip of the tongue. In all he found an infected lower wisdom tooth. Extraction of the tooth effected a cure in four to eight weeks.

Government Control of Mineral Waters

The Société belge d'hydrologie et de climatologie médicale has prepared a prospectus in which it defines natural and artificial waters. It suggests that every enterprise having for its object the collecting, exploitation, treatment, production and sale of drinking waters and mineral waters should be subject to government authorization. Such authorization should be dependent on the chemical analysis, bacteriologic examination, physical and chemical properties, location of the source, and conditions under which the water is collected. Furthermore, the trade name may not be identical with that of any other water already authorized in Belgium. A water may not have a geographic name unless a second name is added. Containers must bear labels showing the contents, whether natural or artificial water. Natural waters shall be understood to mean only waters that are offered for sale in the condition in which they are furnished by nature. Artificial waters which contain added substances must be so labeled and may be sold only by pharmacists. Two kinds of natural waters must be distinguished: (1) medicinal waters and (2) table waters. A special commission, serving under the Conseil supérieur d'hygiène, will supervise enforcement of the regulations.

Surgical Treatment of Varicose Veins

At a recent meeting of the Société belge de chirurgie, Dr. De Beule stated that he had employed all the surgical forms of removal of varicose veins, and that at present he is using sclerosing injections. De Beule employs mercuric iodide or sodium salicylate. A simple procedure is first to ligate the internal saphenous vein, which allows the injection of a greater quantity of liquid. De Beule injects sometimes as high as 15 cc. of a 20 per cent solution. The procedure makes it possible to distribute the liquid throughout the whole extent of the vein. There have been no untoward results in about sixty cases. The patient should stay in bed for a week, and the leg should be provided with a tight-fitting bandage, as in the treatment of phlebitis.

ITALY

(From Our Regular Correspondent)

Feb. 28, 1926.

International Congress of Surgery

The seventh International Congress of Surgery will be inaugurated in Rome, April 7, with Professor Giordano, senator, and surgeon of Venice, in the chair. The following subjects will be discussed: Radium therapy in uterine cancer, by Bentner, Geneva; Donaldson and Fosdick, London; Pestalozza, Rome; Recasens, Madrid, and Regaud, Paris. Abscess of the liver, by Dominici, Sassari, Italy, and Petridis, Alexandria, Egypt. Therapy in cerebral tumors, by Adson, Rochester, Minn.; Bastianelli, Rome; Brun, Lucerne; De Martel, Paris; Lozano, Saragossa, and Percy Sargent, London. Surgery of the spleen, by Cortes Llado, Seville; Henschen, Saint Gallen; Leotta, Bari; Papagannon, Ghezireh, and Ratel, Lyons. An exhibit of sanitary equipment will be held at the congress.

Society for the Study of Tuberculosis

The Società di studi sulla tubercolosi, founded by the Società di medicina interna following the congress of Padua, will hold its first congress in Milan in October. The main theme on the program, "Pneumothorax in the Treatment of Pulmonary Tuberculosis," will be treated by Professors De Bonis of Naples and Carpi and Ronzoni of Milan.

Defense Against Malaria

At a meeting of the Accademia dei Georgofili, held in Florence, March 7, Prof. Giacomo Del Guercio read a paper entitled "A Contribution to the Study of the Defense Against Malaria," in which he communicated researches on a microorganism that opposes malaria. This microbe attacks not only the adult parasite but also the larvae and nymphs found in the water.

A Celebration in Memory of Maurizio Bufalini (1787-1875)

In celebration of the fiftieth anniversary of the death of Maurizio Bufalini, who may be regarded as the founder of modern Italian medicine, Cesena, his native city, held, December 20, a procession which deposited a wreath on Bufalini's monument and a formal gathering at which the ideas of the master were set forth by various speakers. In memory of the occasion a monograph by Prof. Augusto Murri, a pupil of Bufalini, pointed out the master's importance as an educator of physicians. A memorial by Professor Cardi also demonstrated Bufalini's ideas with respect to the medical curriculum.

An Historical Institute of the Art of Healing

The Istituto storico italiano dell' arte sanitaria was established, some time ago, and has for its object the collection and display in a special museum in Rome of material pertaining to the healing art. The important collections belonging to the Museo Flajani in Rome have already been transferred to the new institute, and further valuable material will be contributed by the civil hospitals of Turin, Vercelli and Alexandria, and by the war department. The minister of the interior has urged the prefects of the realm to induce hospital administrations and health societies in their districts to contribute material.

Recognition of War Service in the Adjustment of Pensions of Health Officers

According to a recent decree which increases pensions of health officers, every war campaign is reckoned as a year of service, and the dues that those insured in the Cassa di previdenza (government insurance fund) would otherwise pay are remitted for a corresponding length of time.

A Biennial Hygienic and Health Exhibit

The governor of Rome is considering founding in that city a biennial hygienic and health exhibit, which will serve as a clearing-house for the innovations of the various nations and regions of Italy that take part. Each successive exhibit will be directed toward a different branch of hygiene and sanitation.

The Antigoiter Crusade

Prof. Giuseppe Sangiorgi, director of the hygienic institute of the University of Parma, has recently conducted a scientific inquiry on goiter in Piedmont, a region of Italy in which endemic goiter is prevalent. The inquiry has proved that the contributory causes usually invoked, such as syphilis, alcoholism and consanguineous marriages, are of little or no significance in the genesis of hyperthyroidism. It has also confirmed that cretins ordinarily develop symptoms soon after birth, following an attack of sickness. A point of contact with Brazilian trypanosomiasis confirms Professor Sangiorgi in the hypothesis that cretinism may be a parasitic disease. And since the surroundings in which cretins live are usually unhygienic, their dwellings being often mere shacks, Professor Sangiorgi urges that the authorities improve the dwellings in affected regions as a prophylactic measure. For a number of years past, iodized chocolate wafers have been distributed to the school children in certain districts of Piedmont. The practice has now been extended to the whole civil population by means of table salt containing 1 Gm. of potassium iodide per hundredweight of salt.

NETHERLANDS

(From Our Regular Correspondent)

March 6, 1926

Working Hours of Nurses

There are still some institutions in which the working day for nurses comprises eleven or even eleven and a half hours. Persons most concerned recently voted to address the government with a demand for regulation.

The Crusade Against Frambesia in the East Indies

Dr. Winckel, public health officer in Java, spoke recently at The Hague on the crusade against tropical frambesia in the Dutch East Indies. During the period 1919-1924, more than a million injections were given, for which 500 Kg. of neo-arsphenamine was used. In some regions, the disease may be regarded as completely eradicated.

The Milk Question

Dr. Van Leersum has been carrying on a campaign through the daily press to obtain better milk service. There is an increasing demand on the part of the public for untreated milk. The only way to supply safe untreated milk is to secure good hygiene at the point of production and all along the line. The only efficient method would be to instruct the working personnel in the same manner that we instruct the personnel of an operating room. It is easy to develop such a project without appreciably adding to the cost. Professor Van Oven, in an article in the *Tijdschrift voor Diergeneeskunde,* gives an account of the organization created at Reading, England, where everything seems to be functioning satisfactorily.

Attempted Merger of the Health Insurance Societies

A movement was recently launched to bring about a merger of the health insurance societies of the Netherlands and to centralize their organizations and administrations. The movement proceeded so far that a commission was appointed to represent the principal existing societies. The physicians chosen to serve on the commission were members of the Nederlandsch Maatschappij tot Bevordering der Geneeskunst, and represented, respectively, the general practitioners and the medical specialists. There are at present an almost countless number of health insurance societies. Some organizations count their membership by the tens of thousands, while many smaller societies have only a few hundred members. Each society, however, must have a complete organization. An enormous waste of effort and money is thereby involved. To lessen the waste of energy it was proposed to substitute one immense organization for the present infinite number of small societies. At first sight, the project seemed acceptable; but by such a plan one society would have almost absolute power. This would constitute a grave danger for the medical profession, which consequently has become opposed to the project.

Smallpox, Alastrim and Vaccination

Under the chairmanship of Prof. Ricardo Jorge, an international commission composed of members of the health section of the League of Nations met recently at The Hague to study the questions of vaccination, smallpox and alastrim. The commission sent a questionnaire to all organizations that prepare smallpox vaccine, in order to learn the different methods employed in titration of the lymph, thus looking toward the adoption of a universal standardized method. The commission will also inquire into cases in which disorders of the central nervous system have followed vaccination. These cases, though very rare, in view of the immense number of vaccinations performed, are deserving of careful study. The commission has also appealed to the health section of the League of Nations in order that the cooperation of all the nations concerned may be secured.

The Press and Public Health Propaganda

Owing to the cooperation of all the public services and with the aid of certain private persons whom Dr. Josephus Jitta has interested in his plan, communications of the health council will be sent to all the journals and reviews that have consented to aid the new plan of disseminating information on health topics through the public press.

Tuberculosis Among Teachers

In the *Tijdschrift voor sociale Hygiene,* M. Putto has launched a campaign for medical supervision of members of instructional corps. The dangers to which pupils may be exposed by a tuberculous instructor would indicate that all instructors in schools should be required to submit to periodic physical examinations.

Care of Psychopathic Invalids

A committee has recently been formed, consisting of medical psychiatrists, for the purpose of studying the question of what constitutes proper training of nurses who are to care for psychopathic invalids. It will endeavor to determine what mode of instruction, what kind of education, and what qualities of character and disposition are best fitted for work of that kind. It will consider also the question as to what groups of psychopaths are in need of the care of such personnel. Also the organization, the enlistment and the salary schedule of the personnel will be discussed.

BUENOS AIRES

(From Our Regular Correspondent)

March 1, 1926.

Llama Syphilis Serum

In previous letters, reference has been made to the claims of Drs. Lancellotti and Jauregui as to the discovery of a curative serum for syphilis. The lay press exploited the matter and even announced it as a national achievement. Only a few weeks ago, pictures appeared in the newspapers of the 100 llama herd imported for the preparation of serum. The medical societies, however, could get no definite information on these studies. Drs. Lancellotti and Jauregui asked Dr. Chabroux to verify the effectiveness of their serum. Dr. Chabroux has now published in *La Semana Médica* his first report. Lancellotti and Jauregui stated that the serum from immunized llama rendered a negative Wassermann test. The serum placed in Chabroux' hands showed a positive test. Lancellotti and Jauregui claimed that they had secured splendid results within from six to twelve days in confluent patches and ulcerated papules, after previous treatments had failed. Chabroux did not see any improvement in such cases, but on the contrary, there were recurrences during treatment, even when using a dose three times as large as that originally advised. The Wassermann test did not become negative, and the action on mucous lesions proved short lived. After the serum had failed so signally, neo-arsphenamine made the lesions disappear and changed the Wassermann test to negative.

Medical Entomology

The recent and untimely death of Dr. Juana Petrocchi, already noted for her entomologic work, left vacant the position of chief of the entomologic division of the national department of health. Through the agency of the Rockefeller Foundation, Mr. William Shannon, an American, has been appointed to replace her. Dr. E. del Ponte will aid him in his studies of insects as disease vectors. Dr. del Ponte is at present engaged in a study of Chagas' theory that anopheles are really domestic insects, as the verification of this fact is important in prevention work.

Foreign Experts

The national department of health and the Clinical Surgery Institute (headed by Professor Arce), have engaged Prof. G. Fichera of Italy to take charge of pathologic work in both institutions.

The Rosario Medical School has also sent for Prof. G. Viale, a young man recently appointed at Sassari, to direct its well equipped physiologic laboratory. It seems strange to go abroad in order to fill such places, when there are two large institutions of this type in Buenos Aires, where a number of young men have been trained and have gained prominence. Many argue that a system of fellowships abroad is preferable to importing experts. The latter method has been tried here for many years, with results far from satisfactory.

The national department of health has also tendered the position of inspector of local laboratories to Prof. R. Kraus, the former director of the National Bacteriologic Institute.

Malaria

New antimalaria stations have been opened at San Lorenzo, Salta, and Tafí Viejo, Tucumán. Antimosquito work is being continued at Jujuy, Salta, Famaillá and Monteros, and is just being started at Aguilares, Tucumán. Dr. Amarante, the chief of the malaria division, has gone to Catamarca, to consider extending the work to that district. In addition to his studies of anopheles, Dr. del Ponte is studying the comparative value of several larvicides, including paris green.

Tuberculosis

The Argentine League Against Tuberculosis has opened a new sanatorium and dispensary at Rosario, whence a large region can be reached. The funds for the purchase of the building were a gift of Dr. Bartolomé Vassallo.

Externs

After a number of difficulties, hospital internships were discontinued about a year and a half ago. Now the Public Assistance has suggested that the Buenos Aires Medical School should take the responsibility of appointing the 291 "externs" who must serve in the hospitals.

Trachoma

For a number of years, ophthalmologists have pointed out the increasing number of foreigners with trachoma, especially Italians, Spaniards and Syrians, appearing at dispensaries. After a long neglect of prevention measures, all trachomatous immigrants are now refused admission, the steamship companies being required to repatriate all such cases. The disease has been controlled through a vigorous campaign in the capital. In addition to the hospital outpatient departments, the national health department has opened a special trachoma clinic in charge of Drs. A. Barbieri and E. de la Vega. The disease has spread in certain extensive zones in the provinces of Santiago del Estero, Tucumán and Jujuy; but an active campaign is already in progress.

Prizes

Through Dr. S. Dessy's efforts, a fund has been collected to institute a Guido Banti memorial prize in pathology. Awards will be limited to Argentine or Italian medical students.

The Argentine Biological Institute is offering an international prize, amounting to 1,000 pesos (about $400), for the best experimental work on bacteriology, biochemistry or endocrinology.

Postgraduate Studies

Dr. Valls has completed his postgraduate course in orthopedics at the Rizzoli Institute in Bologna. Dr. Dellepiane Rawson will now follow him.

After completing at Torino and Berlin the followships in physiology and physical chemistry granted by the Argentine Biological Institute and the Buenos Aires University, Dr. E. Hug has returned home.

Dr. R. Finochietto has left for Europe to inspect cripples' rehabilitation institutions.

Dr. Diez has also left to look into recent developments in nerve surgery.

Dr. Nierenstein has been granted a fellowship by the Buenos Aires University.

After spending some time in biochemical laboratories abroad, Dr. C. T. Rietti has returned to Argentina.

The Rockefeller Foundation has been requested to extend the fellowships granted to Drs. M. Balado (experimental surgery) and J. T. Lewis (physiology).

Medical Congresses

The fourth South American Conference on Hygiene, Microbiology and Pathology will be held at Buenos Aires, July 8-18. The committee in charge consists of Dr. G. Araoz Alfaro, president; Drs. D. J. Cranwell, A. Sordelli, M. V. Carbonell, F. A. Justo, A. Bachmann and B. A. Houssay, vice presidents, and Drs. A. Zwanck and S. Mazza, secretaries. The arrangements for the meeting on medical education have been placed in the hands of a committee composed of D. J. Cranwell, president; B. A. Houssay, P. Chutro, A. Lanari and J. Iribarne, vice presidents, and O. Loudet and V. A. Fiori, secretaries. Foreign committees have already been organized in Brazil, Chile, Paraguay, Peru and Uruguay.

In August, 1926, the first Argentine Surgical Congress will be held. The officers appointed are: D. J. Cranwell, president; L. M. Allende, E. Belaustegui, A. Ceballos and M. Ruiz Moreno, secretaries.

New Journals

The *Archivos Oftalmológicos de Buenos Aires* is already in its third issue. The editor is Dr. R. Argañaraz, assisted by Drs. H. Rebay, E. Adrogué, Lijó Pavía and thirty-six collaborators.

Prof. C. Bonorino, with a select group of collaborators, either clinicians, surgeons or radiologists, has started publication of *Archivos de Enfermedades del Aparato Digestivo y de la Nutrición.*

Dr. Molina's Death

February 16, Dr. S. Molina died. In addition to being the dean of the Argentine medical profession and a former director of the Rivadavia Hospital, he was also the real pioneer in modern obstetrics, and filled the first obstetric chair in Argentina.

BERLIN

(From Our Regular Correspondent)

March 20, 1926.

The Düsseldorf Exposition

The Düsseldorf exposition, which will open, May 8, will cover an area of 400,000 square meters and will deal with health culture, social welfare and physical education, thus fulfilling the same purpose as "Health Week" (THE JOURNAL, April 24, p. 1304). The exposition buildings, the more important of which will be permanent structures, will have a total area of 12,000 square meters. According to the announcements of Geheimrat Schlossmann (Dusseldorf), who is the director of the exposition, a more or less prominent part in preparing the proposed exhibits will be taken by the federal insurance institute for employees *(Reichsversicherungsanstalt)*, the leagues of the health insurance societies, the trade unions, the provincial insurance institutes, the ministry of federal defense, the institute of tropical hygiene (Hamburg), the Hygienic Museum of Dresden, the International Red Cross, the health commission of the League of Nations, the several states of the German federation, numerous large cities, the leagues of the welfare societies, and numerous care-taking centers. The comprehensive exhibit that will be grouped under the name "Home and Settlement" will give a survey of modern fire-fighting equipment, water systems, sewerage systems, building construction, gas and electric installation, heating and ventilation, food, condiments, beverages and clothing. In the exhibit "Sport and Physical Education," the visitor will find sport and gymnasium equipment of all kinds, from a large sailing yacht down to a football, a modern gymnasium, plans and models of modern athletic grounds, and, above all, a survey of aeronautics. In the preparation of the exhibit "Care and Treatment of the Sick," the universities, the Akademie für praktische Medizin and numerous special clinics have collaborated in the presentation of the results of their modern researches. The German spas and health resorts also have a special exhibit. Another exhibit that promises to be particularly interesting bears the designation "Man in His Hygienic Relations to Plants and Animals," which affords a survey of the science and technic of modern agriculture. Of the special buildings, those that are of interest are the physicians' building, the women's building, the Austrian building, and, finally, the Düsseldorf building, in which this city on the Rhine, justly famous for its art, its gardens and its industries, presents a miniature likeness of itself.

Causative Agents of Cancer

Professor van Calcar in the Netherlands and also Dr. Schumacher, microbiologist of Berlin, have recently reported discoveries of "new causative agents of cancer." In an article in the *Deutsche medizinische Wochenschrift*, Professor Blumenthal, director of the Berlin Institute for Cancer Research, refers with considerable skepticism to the alleged findings. I quote from his article as follows:

Van Calcar regards the protozoa that are found in oats, barley and other grains, worms, bugs and insects, as the causative agent of cancer. In previously moistened grain, which he exposes to the air and allows to dry, he enriches the protozoa and asserts that with such fluid, which, in addition to protozoa, contains also bacteria, he has produced cancer in dogs. He maintains further that these protozoa pass through an invisible stage, for which reason they are not seen, in spite of the fact that they are associated in symbiosis with the cancer cell. From human cancer tumors he cultivates the protozoa in the following manner: He allows decoctions of barley and oats prepared with sterilized water, into which he has deposited pieces of cancer tissue, to stand in nonsterile vessels. After twenty-four hours he removes the covers and leaves the vessels open until the contents have evaporated to dryness, whereupon water is added. In this fluid he finds fusiform, tremulous protozoa, which he designates as causative agents of cancer. This fluid but not isolated protozoa, was fed to, or injected into, dogs whose gastric secretion had been eliminated or in which burn blisters had been elicited. The gastric secretion was eliminated because, according to Calcar's view, achylia gastrica creates a disposition to cancer. It is alleged that nodules developed in the gastro-intestinal tract (or at the site of the injections) which were, for the most part, very small. In one instance, a larger tumor was found, which, to judge from the illustration, may possibly have been a true cancer. There is no reference to any attempts to discover whether or not the alleged tumors could be transplanted. Many things, especially the method, remind one of Feinberg's experiments many years ago. Calcar maintains that endeavors to produce tar cancer in mice fail utterly if the tar is applied to a region practically free from protozoa. Even if we assume that Calcar did succeed in producing cancer in dogs, it does not necessarily follow that the tremulous protozoa noted in the open fluid were the causative agent. It is equally likely that an invisible virus instituted the offensive. In any event, it cannot be admitted that Calcar's experiments justify his far-reaching conclusions.

As to Schumacher, he was unable to isolate his causative agent of cancer from the cancer tissue, for which reason he could not test it to ascertain whether or not it could produce tumors. The evidence adduced for the existence of the alleged causative agent is based solely on the facts that Schumacher was unable with the ordinary stains to demonstrate the presence of parasites but that when he used a certain method, as yet undivulged, but which included staining with Victoria blue, he demonstrated in the connective tissue at the margin of the cancer and at the dividing line between the diseased and the healthy tissues, with a magnification of 60, large S-shaped, wide, blue markings in such large numbers that they occupied a tenth of the marginal space about the cancer. He declares, without further investigation, that these formations constitute the causative agent. It is very doubtful whether the stained markings that Schumacher describes represent living organisms at all. It is quite possible that they are merely tissue components. A living organism of such size and existing in such great numbers ought to be visible in dark field illumination. Schumacher's communication does not, therefore, seem to me to furnish a basis for further discussion.

Society Proceedings

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Twentieth Annual Meeting, held at New York, March 30-April 1, 1926

Fracture Dislocation of the Neck

DR. ALFRED S. TAYLOR, New York: The number of fracture dislocations in the cervical spine seems to be increasing with each succeeding football season, and each summer also furnishes its toll of similar serious injuries from diving accidents. The bone lesion is usually of relatively minor importance. The seriousness of the injury depends entirely on the injury of the nerve tissues involved. The aim of treatment must be to restore the nerve structures to as near normal as possible. The first principle of treatment is not to manipulate the patient. The second principle is to restore proper anatomic relations of the various injured structures as far as possible. The third principle is to apply fixation apparatus which shall reach from the iliac crests upward to the chin and occiput, and which shall cause some elongation of the cervical spine as well as slight backward extension. The principle of the method I employ consists of controlled traction exerted on the head (with countertraction on the lower extremities) until the spasmodically contracted cervical muscles have relaxed sufficiently to permit reduction by bimanual manipulation on the part of the operator. Fixation is maintained by a plaster jacket encasing the trunk and neck. This jacket is kept on for three or four weeks; then a spinal brace with jury mast and cupped arrangement to fit and hold up the chin, jaw and occiput are used. Open operation in the acute stages of these injuries, because of the handling necessary to posturing the patient on the table and returning him to bed, involves great risk of added injury to the cord. The removing of the arches takes away a large part of the remaining stabilizing apparatus at the site of injury. In the old cases, in which it is impossible to get a good reposition, the only thing to do is to put on a fixation apparatus for a sufficient length of time so that the spine will become solidly ossified in its position of deformity.

DISCUSSION

DR. FOSTER KENNEDY, New York: I was associated with Dr. Taylor in two cases in which this method was used. Besides immediate result in the bone reduction, there was tremendous improvement in the cord symptoms.

DR. HENRY KELLER, New York: I have seen three cases which illustrate that one cannot tell by the symptoms the extent of the injury. Two were cases of complete fracture dislocation, one of the third, the other of the fourth cervical. One patient presented no symptoms at all. The only suspicious sign present was the fact that the child walked in with the head down, chin on the chest. The roentgen ray showed complete fracture dislocation of the third cervical. Hence, it is very important in every case of injury of the neck region to make a roentgen-ray examination.

Ventriculometry

DR. K. WINFIELD NEY, New York: The value of ventriculometry lies not only in definitely determining the increase in intracranial pressure, but also in accurately measuring the degree of this pressure. The normal intraventricular pressure is approximately the same as the pressure of the spinal fluid, namely about 8 mm. of mercury. Pressures have been recorded from 0 to 65 mm. of mercury. The lower pressures are mostly in the after-effects of cerebral vascular thromboses, and certain types of epilepsy and dementia praecox. Higher types are in encephalitis, 65 mm.; the so-called communicating type of hydrocephalus in adults, from 40 to 60 mm.; cerebral tumors and abscesses, from 25 to 35 mm., and congenital hydrocephalus, from 8 to 40 mm.; hydrocephalus due to posterior fossa tumors, from 15 to 30 mm.; chronic brain injuries showing post-traumatic neuroses, from 16 to 22 mm. Tapping the posterior horns of the lateral ventricle for pressure determination is a safe procedure with considerable less discomfort than spinal puncture.

Diagnosis and Localization of Brain Tumors

Dr. Walter E. Dandy, Baltimore: There are few, if any, tumors which should not be diagnosed and precisely localized by the use of air injections if other means fail. Air injections should be used only when the necessary information cannot be obtained from neurologic examination. They are also used to exclude tumors if there is a question of doubt as to the diagnosis. The method is not harmless. If it is not used correctly, it is one of the most dangerous tests employed for diagnosis. If it is used correctly, there is no danger. For the last six years we have not had a single death, and when judiciously used, there can be very few, if any, symptoms produced. If correctly used, it can make a localization of practically all brain tumors.

DISCUSSION

Dr. S. Philip Goodhart, New York: This method of localization of brain tumors offers the only opportunity for therapy in neurology. The merits of this diagnostic method are universally conceded. We are beginning to hear reports that are very favorable. Recently, Grant of Philadelphia presented an analysis of 400 cases in which he states that the diagnosis was practically made in 80 per cent by Dr. Dandy's method of localization, and in 30 per cent by that method alone. In that series of cases, 50 per cent of the patients were operated on successfully. This method is also a great help in that hitherto baffling situation in which the symptoms indicated tumor, there being a tremendous amount of intracranial pressure, and the operation revealed practically nothing. Many such cases are due to inflammatory processes.

Dr. Charles A. Elsberg, New York: While the technic of air injection is simple, the manipulation of the head after the air has been injected is not so simple. Sometimes the air will not pass from one lateral ventricle into the other as it should, if the side into which the air was injected is down, so that the air can rise through from the foramen of Monro into the other side. The method is not simple when it comes to obtaining good ventriculograms, or in their interpretation. Every once in a while it is difficult to say from the ventriculograms with real certainty exactly where the tumor lies, so that there are some patients in whom even ventriculograms will not lead to a positive localizing diagnosis. In such cases, repeated injections of air may be necessary with pictures taken in various positions, study of the ventricles by injections of dye into one or both of them, etc. One must not arrive at the conclusion that with this method of diagnosis all infiltrating tumors can be removed. By no means. While the method does help and is extremely valuable, it has not yet solved for us all the problems of infiltrating tumors of the brain. Ventriculography has been a tremendous step in advance; I am becoming more and more enthusiastic as to its use, but the ideal has not yet been reached. The ideal will be attained when an absorbable fluid impervious to the roentgen ray, and not toxic, will be discovered which can be injected into the ventricles; with one stereoscopic roentgenogram we shall then obtain all the information needed, and we shall not be obliged to have roentgenograms taken in various positions, and shall not have to depend on the passage of air from one ventricle into the other.

Dr. Israel Strauss, New York: The neurologist can probably localize about 70 per cent of the neoplasms of the brain. Without this method he would be at a loss. With it, properly applied, his diagnosis in localization ought to be absolute. This method cannot be utilized by an assistant injecting air into the ventricle, and another assistant taking the patient to the roentgen-ray department and then the radiologist attempting to interpret the results. It is a one-man method. It requires the attention of the surgeon in every phase, and that is where the difficulty has arisen. It means a great deal of experience in the interpretation of what one finds, and a great knowledge of anatomy and pathology. Dr. Ney's work is of a great deal of importance, for the reason that, with the determination of the ventricular pressure, it becomes unnecessary to resort to the injection of air. The information obtained by recording the size of the ventricles may be sufficient in conjunction with the neurologic signs to make a diagnosis and a localization.

Dr. K. Winfield Ney, New York: There can be no question regarding the value of ventriculography in the localization of brain tumors, but the technic must be mastered and followed.

Dr. Walter E. Dandy, Baltimore: I think I have probably given the wrong impression about the number of cases in which air has actually been used. Three or four years ago we published a method called "ventricular estimation" from which we could get practically the same results as from actually seeing the ventricles thrown on a photographic plate. In many cases, ventricular estimation has been used instead of the actual injection of air. Localizations and diagnoses so made are included in the estimate of one third of brain tumors requiring air injections.

Cholecystography by the Oral Method

Dr. William H. Stewart, New York: For cholecystography by the oral method we are using tetraiodophthalein obtained in sealed colored ampules, a single dose in each, which has overcome the deterioration question. The method is simple and efficient. Some authors have claimed there is more reaction following the oral than the intravenous injection, but this has not been our experience. We have either had no reaction, or a slight nausea or one or two loose movements. When a reaction occurs, it does not incapacitate the patient. We do not admit that the oral method is less valuable than the intravenous. We take exception to the statement that the oral method should be checked with the intravenous. The examination is not simple. It requires a patient who is intelligent enough to suspend respiration during the making of the films. One of the most important phases of the Graham test is in the deduction of a disturbance of the function of the gallbladder. One important use of the method of visualization of the gallbladder is the differential diagnosis between nephrolithiasis and cholelithiasis. It is much simpler to carry out the gallbladder technic than to outline the kidney pelvis and calices by pyelography.

DISCUSSION

Dr. Lester Levyn, Buffalo: Many roentgenologists have abandoned the intravenous method because it is generally followed by varying degrees of reaction. Technical difficulties are frequently encountered. The danger of injuries to the peripheral vessels is a serious one. Bacterial contamination is possible, and certainly it is not to be recommended as an office procedure. Hanzlik has shown definite changes in the physical characteristics of the blood as the result of various types of intravenous medication. These reactions are not encountered when the dye is administered by mouth. Slight nausea or occasional vomiting may occur, but never a severe reaction. If comparable results may be achieved by the oral method, why subject patients to the discomforts and dangers of intravenous injections, except in occasional cases in which visualization is not obtained after at least two oral attempts have been made? In the majority of cases, practically 80 per cent, the oral method is successful. Our percentage of visualization with keratin coated capsules has not been as high as Dr. Stewart's. We give the dye in a number 0 capsule inserted in a number 3 capsule which contains sufficient sodium bicarbonate to cover completely the dye contained capsule. In this manner we have found that the greatest amount of protection against the acid gastric juice is obtained and more soluble dye is available for absorption than by any other product. The accurate interpretation of cholecystography will be arrived at only by collaboration between clinician and roentgenologist.

Dr. Merrill C. Sosman, Boston: We have a record of 400 cases studied by the oral and 200 by the intravenous method. The obvious difference in the two methods is this: In the oral method an unknown amount of the dye is absorbed, while in the intravenous method a known quantity of salt is put into the blood which must come through the liver to the gallbladder. We have found the intravenous method much more accurate than the oral method. With the intravenous method we have had 93 per cent of cases proved by the surgeon and the pathologic report, as against 80 per cent with the oral method. Of 113 cases in which operation was done, the diagnosis was confirmed in 105. As a further check on the oral method, fifty-six patients who showed no shadow by this examination were subsequently given the intravenous test. In only forty-one of them were the findings confirmed, an accuracy of 73 per cent. Likewise, in forty-three medical students, oral examination gave normal shadows in only thirty-three, and faint shadows in the remaining ten. We use the oral method in ambulatory cases and accept the results showing normal shadows or stones. The others we confirm or disprove by the intravenous method.

Dr. Israel O. Palefski, New York: Dr. Stewart, I fear, places too much dependence on the results of the oral method. Employing the same method of preparation of the dye capsules and observing the same precautions as he does, I found a large group of patients in whom the dye failed to reach the liver and the gallbladder in sufficient quantities to permit accurate clinical deductions. The oral method often failed us in the crucial cases. Its present vogue is undoubtedly based more on its simplicity of application than on its accuracy. Conclusions based on this method should be stated reservedly. On the other hand, I see no objection to the intravenous method, if performed properly. It is unfortunate that the unpleasant consequences that followed the intravenous tetrabromphenolphthalein procedure should be unduly attributed by some observers to tetraiodophenolphthalein without giving it sufficient trial. The general reaction, if any, is certainly less than after the oral method. As a rule, there is no reaction after a dose of from 2 or 2.5 Gm. of tetraiodophenolphthalein dissolved as a 5 per cent solution in distilled water and introduced by means of a 50 cc. finger holed syringe. The intravenous method is not only labor saving, as it usually requires one examination, but is accurate in determining the patency or nonpatency of the cystic duct, the main feature of importance in cholecystography.

Dr. Louis Lefrak, New York: It is my opinion that Graham and his associates have put before us a Pandora's box of troubles. The technical difficulties, great as their number are, will probably be shortly overcome, but the interpretation of the gallbladder shadows will tax the patience of all of us. The normal gallbladder will have to be discovered before we can describe the pathologic organ in all its ramifications.

Dr. William H. Stewart, New York: We concede that the oral method is not more accurate than the intravenous method, but we believe we can get the same information by the administration of the dye by mouth as by the intravenous injection. We have given up the intravenous method. It has been very discouraging. The first thing is the severity of the reaction; in some instances we almost lost the patient. Another ill effect is a very severe sloughing from a drop of the solution getting into the soft tissue; this occurred more than once. Another thing that may happen is phlebitis.

Muscle and Nerve Injuries Associated with Fractures

Dr. Dean Lewis, Baltimore: Nerve and muscle injuries associated with fractures are relatively rare, but they so prolong the disability that they demand early recognition and intelligent therapy. In 80 per cent of the nerve injuries, the humerus is the bone that is fractured, the common site of the fracture being in the lower third of the bone (60 per cent). Of the peripheral nerves involved, the musculospiral accounts for 60 per cent and the ulnar nerve for about 25 per cent. Many of the latter, however, are late paralyses. Next in order of frequency are injuries of the median nerves associated with anterior displacement of the lower end of the upper fragment of the humerus, and dislocation with displacement forward of the carpal bones. Isolated injuries of different nerves are observed, but the musculospiral, ulnar and median are the nerves most frequently injured. Injuries of the musculospiral nerve with fractures of the surgical neck are uncommon. The nerve is well protected at this point. Injuries of the musculospiral are most common with fractures of the middle of the shaft and supracondylar fractures in which the upper end of the lower fragment is displaced outward. In the spiral fracture through the middle of the shaft, the upper end of the lower fragment is frequently displaced outward and the musculospiral nerve is first contused and then stretched over the fragment. In some of the fractures through the lower third of the humerus, the musculospiral nerve seems to be torn at its most fixed point, just above the origin of the deep branch. This type of injury is uncommon; but when an injury of the nerve is not found at the site of the fracture, it is well to explore the nerve in the antecubital fossa. Ulnar nerve injuries may be associated with fractures of the internal epicondyle and condyle and supracondylar fractures. The most interesting ulnar injuries are those in which the symptoms develop late. A history is given of injury of the elbow in childhood followed by good recovery of function. Later, varying from ten to thirty or forty years, definite symptoms of ulnar nerve palsy develop. This late ulnar palsy is most frequently associated with a cubitus valgus due to an ununited fracture of the external condyle. The deformity, a prominent internal condyle, with a cubitus valgus and impaired extension, should suggest at once a late ulnar palsy. Many have been diagnosed cervical rib, syringomyelia, etc. Injuries of the median nerve are frequently overlooked, for the disability following median nerve injuries is slight, consisting of the inability to flex the index finger, to use the opponents and flexor longus pollicis.

Ischemic myositis (Volkmann's contracture) is one of the most disabling lesions associated with fractures. It is observed most frequently after supracondylar fractures and fractures of the lower end of the femur. It is caused by venous congestion. About 18 per cent of the cases of ischemic palsy occur without a cast or constricting dressing having been applied. The importance of the subfascial hematoma in the production of ischemic palsy has not been fully appreciated. In cases with marked swelling and induration of the antecubital fossa, no attempt at reduction should be made—no dressing applied. The internal pressure due to the hematoma should be released. Incision of the fascia with evacuation of the clot is advisable. The mild cases may be cured or greatly improved by elastic traction and massage; but if the greater part of the contractile substance has been destroyed, operation is of little avail, for lengthening of tendons or muscles is of no avail if the contractile substance has been destroyed. A fracture should not be considered merely as a fracture, but a careful examination should be made for associated injuries of nerves, muscles and blood vessels.

DISCUSSION

Dr. William Darrach, New York: I should like to emphasize what Dr. Lewis has said about the possible cause for ischemic paralysis; that is, what we have been calling a pressure from within as distinguishd from pressure from without. A number of cases are on record in which this condition has developed without any constricting pressure from bandage or acute flexion, which can be explained only by some internal cause. In the study of nerve injuries complicating fractures, the most important thing is to emphasize the wisdom of establishing at the first examination the question as to whether the nerve has been injured or not. I know of no more embarrassing situation than to find after the third or fourth examination that a nerve injury exists, and to be uncertain whether the nerve injury was due to the fracture or to attempts at reduction of the fracture. It is surprising how quickly a return of function will sometimes occur in a nerve that looks to be severely injured at the time of operation. The association of nerve injuries with carpal injuries is of importance. Another point is in regard to the late manifestations of ulnar nerve injuries with elbow fractures. That is an illustration of how unreliable the statistics of any one person are. Dr. Lewis stated that he thought ulnar nerve lesions were common because he had seen fifteen of them. I have only seen one. Because one man is especially good at treating these conditions, he gets all the cases, and thinks that their occurrence is more common than it really is. They are tremendously important, but I do not believe that they are very frequent,

Dr. Emil Goetsch, New York: Our commonest nerve lesion with fracture and dislocation has been the median nerve injury due to dislocation of the scaphoid. Another type that has not been mentioned is injury to the circumflex nerve after an impacted fracture of the neck of the humerus. We had one case of musculospiral palsy due to fracture of the shaft of the humerus near its middle and one of musculospiral palsy from a supracondylar fracture of the humerus. In one case the median nerve was involved in the forearm after callus formation following a compound fracture of both bones of the forearm. This occurred three months after the injury. There was one case of brachial plexus palsy in a young boy who was hanging to a strap in a street car, lost his grip and seized his neighbor, hanging on to his shoulder, in this way overstretching his arm. Five roots of the brachial plexus were divided just outside the intervertebral foramen. We had four more, two of the external popliteal, injured at the time of a fibular fracture, two of direct injury at the point of the head of the fibula after dislocation of the knee. The great necessity of immediate examination for nerve injuries cannot be overstressed.

Dr. Alfred S. Taylor, New York: I have had five cases of late ulnar nerve palsies. In each case there happened to be either a transverse supracondylar fracture or a fracture of the internal condyle. I have not seen this associated with the external condylar fractures. In these cases the mechanism of the damage to the ulnar is the same; namely, a distortion of the internal condyle which increased the backward projection of it, which causes stretching and therefore continuous irritation of the ulnar nerve.

Dr. Richard Kovacs, New York: At the Reconstruction Hospital we have seen upward of eighty cases of nerve injuries associated with traumatism. From the standpoint of diagnosis, while the clinical examination alone will in some cases be sufficient to settle the question, the method of electrodiagnosis will greatly assist in the complicated cases. The rule still holds that in any nerve injury the corresponding muscle ceases to respond to the impulse of the faradic current in four days, while after ten days galvanism elicits only a sluggish response. In any hospital with a physical therapy department, the test can be carried out satisfactorily. With the modern methods of condenser testing, response to electrical stimulation can be accurately measured and chartered. When it comes to the question of therapy, physical therapy aids only as an adjuvant; but it will help to maintain the condition of the paralyzed or weakened muscle, so that when the nerve regenerates or its physiologic function returns, instead of degenerated muscle fibers we find those which have kept their main function, that of contraction. The rational and systematic application of physical measures offers considerable help to the surgeon and the orthopedic man.

Dr. Byron Stookey, New York: Dr. Lewis called attention to a very important point—that no examination of a fracture is complete unless examined for a possible nerve injury. I should like to ask why Dr. Lewis would wait for three months before exploring. In a dislocation I have never seen a complete anatomic interruption of the nerves. It is usually a traumatism from which the patient will recover. If the roentgenogram shows a comminuted fracture with sharp points, and the history is obtained of an immediate paralysis, I think it would be wiser to cut down on the nerve and determine its condition, because whether by electrical reactions or otherwise, I know of no signs that will help one to determine whether it is interrupted anatomically. I can see no advantage in waiting three months, as Dr. Lewis suggested.

Dr. Dean Lewis, Baltimore: I quite agree that it is impossible to differentiate between anatomic division of a nerve and the physiologic interruption of conduction. Even the most skilled neurologist is often unable to do this. If a neuroma can be palpated, it is distinct evidence of division or at least a nerve block which requires surgical intervention. I do not employ physiotherapy but use a splint with an elastic attachment, so that each time the part is used it is brought back to a neutral or an overcorrected position. As for waiting three months before operation unless there are indications for immediate intervention, I believe that this gives time for at least the beginning of recovery.

(To be continued)

Marriages

Hamilton Chesley Perkins, Boston, to Miss Caroline Ellsworth Bent of North Sudbury, Mass., in January.

Gerald A. Ezekiel, Richmond, Va., to Miss Julia-May Sommers of Washington, D. C., February 22.

Julius A. Johnson, Omaha, to Miss Ruth Carlson of Chicago, April 24.

Deaths

Albert Brown Lyons ⊕ Detroit; University of Michigan Medical School, Ann Arbor, 1858; professor of chemistry, Detroit Medical College, 1868-1880; consulting chemist for Parke, Davis and Company, 1881-1886; member of the committee of revision of the United States Pharmacopeia from 1900-1920; one of the founders and first editor of the *Pharmaceutical Era*, author of "Plant Names, Scientific and Popular" and "Standardization by Chemical Assay of Organic Drugs" and other works; aged 84; died, April 3.

John Mason Little, Jr. ⊕ Boston; Medical School of Harvard University, Boston, 1901; for two years instructor in minor surgery at his alma mater; for several years connected with the Grenfell Missions in Labrador; at one time on the staff of the Massachusetts General Hospital; aged 50; died, March 24.

Constantine Francis McGuire, New York; Bellevue Hospital Medical College, New York, 1882; member of the Medical Society of the State of New York; on the staff of the Central Neurological Hospital; aged 71; died, April 15, of heart disease.

Rodney D. Ramey, Garden City, Mo.; Missouri Medical College, St. Louis, 1883; member of the Missouri State Medical Association; past president of the Cass County Medical Society; aged 70; died, April 6, of heart disease.

Zenas Lockwood Leonard ⊕ Pittsfield, Mass.; Medical Department of the University of the City of New York, 1880, aged 68; died, April 4, at St. Bartholomew's Hospital, of carcinoma of the sigmoid flexure of the colon.

Frederick King Shaw ⊕ Concord, Mass.; Medical School of Harvard University, Boston, 1902; chairman of the board of health; served during the World War; on the staff of the Emerson Hospital; aged 55; died, April 5.

James Michael Collity, Manchester, N. H.; Bellevue Hospital Medical College, New York, 1879; member of the New Hampshire Medical Society; for many years city physician; aged 71; died, March 27, of pneumonia.

Joseph Albert Pettus, Athens, Ala.; University of Nashville Medical Department, 1868; member of the Medical Association of the State of Alabama; Civil War veteran; aged 80, died, April 6, of organic heart disease.

Alfred E. Fretz ⊕ Sellersville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1896; on the staff of the Grand View Hospital; aged 51; died, March 30, at the University Hospital, Philadelphia.

Morgan J. Williams, Scranton, Pa.; Medical Department of the University of the City of New York, 1881; member of the Medical Society of the State of Pennsylvania; aged 76; died, in March, of heart disease.

Prescott Tallman Mitchell, Cincinnati; University of Cincinnati College of Medicine, 1923; member of the Ohio State Medical Association; served during the World War; aged 31; died, April 1, of pneumonia.

George Burley Martin, Asheville, N. C.; Medical College of Virginia, Richmond, 1910; member of the Medical Society of Virginia; served during the World War; aged 43; died, April 11, at a hospital in Oteen.

James Benjamin Padgett, Ruffin, S. C.; Baltimore University School of Medicine, 1887; aged 61; died, March 23, at the Charles Es'Dorn Hospital, Walterboro, of chronic nephritis and heart disease.

Alexander Grier Appleby, Valley City, Ohio; College of Physicians and Surgeons, Baltimore, 1895; member of the Ohio State Medical Association; aged 52; died, April 4, of cerebral hemorrhage.

⊕ Indicates "Fellow" of the American Medical Association.

William Hill Bean ⊕ New Haven, Conn.; Yale University School of Medicine, New Haven, 1903; formerly instructor in therapeutics at his alma mater; aged 59; died, Dec. 1, 1925, of angina pectoris.

William Franklin Baugh, Conway, Ark.; University of Arkansas Medical Department, Little Rock, 1885; member of the Arkansas Medical Society; aged 71; died, March 4, of angina pectoris.

Henry M. Collison, Sterling, Colo.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1901; member of the Colorado State Medical Society; aged 51; died, February 26.

Edmund Henry Mitchell, Bakersfield, Mo.; Jefferson Medical College of Philadelphia, 1879; member of the Missouri State Medical Society; aged 68; died, March 30, of heart disease.

Ephraim Waldo Love, Fayetteville, Ohio; Rush Medical College, Chicago, 1881; member of the Ohio State Medical Association; aged 68; died, March 23, of carcinoma of the liver.

Joseph Roa Grant, Auburn, N. Y.; Cornell University Medical College, New York, 1904; served during the World War; aged 51; died, March 26, of pneumonia, following influenza.

Walter K. Smith, *Adairville, Ky.; University of Louisville* School of Medicine, 1884; member of the Kentucky State Medical Association; aged 64; died, April 2, at Lakeland, Fla.

Francis Joel Canedy ⊕ Shelburne Falls, Mass.; University of Michigan Medical School, Ann Arbor, 1870; formerly bank president; aged 79; died, March 30, of pernicious anemia.

John Daniel Walthall, Paola, Kan.; University of Michigan Medical School, Ann Arbor, 1883; aged 66; was killed, March 22, near Osawatomie, in an automobile accident.

David O. Hudson, Montgomery City, Mo.; Missouri Medical College, St. Louis, 1879; formerly county coroner; aged 69; died, March 12, at Columbia, of heart disease.

Harlan Edward Linehan, Brooklyn; Baltimore Medical College, 1907; member of the Medical Society of the State of New York; aged 42; died, March 9, of myocarditis.

Harry Houghton Drake, Johnstown, N. Y.; Albany Medical College, 1909; member of the Medical Society of the State of New York; aged 49; died, April 2, of angina pectoris.

James David McGlamery, Birmingham, Ala.; University of Georgia Medical Department, Augusta, 1924; aged 28; died, March 2, at St. Vincent's Hospital, of pneumonia.

Hector Daniel McKenzie, Oakland, Calif.; Oakland College of Medicine and Surgery, 1918; member of the California Medical Association; aged 35; died, February 18.

Thomas Urquhart Joyce, Brooklyn; Long Island College Hospital, Brooklyn, 1881; member of the Medical Society of the State of New York; aged 78; died, April 1.

Charles Frederick Klippert, New York; Medical Department of the University of the City of New York, 1880; aged 67; died, April 7, following a long illness.

William Kurtz Mathis ⊕ Chanute, Kan.; University Medical College of Kansas City, Mo., 1903; on the staff of the Johnson Hospital; aged 45; died, March 9, of nephritis.

John Albert Burtch, Coffey, Mo.; College of Physicians and Surgeons, Keokuk, 1895; aged 54; died, March 9, at the Noyes Hospital, St. Joseph, of diabetes mellitus.

William James Dunn, Camden, S. C.; Louisville (Ky.) Medical College, 1888; member of the South Carolina Medical Association; aged 62; died, March 12.

George Allan Rowe, Buffalo; Eclectic Medical Institute, Cincinnati, 1879; aged 71; died, April 4, of chronic myocarditis and chronic interstitial nephritis.

Morris S. Cohen, Fitzgerald, Ga.; Jefferson Medical College of Philadelphia, 1881; aged 60; died, February 19, at Cleveland, Ohio, of cerebral hemorrhage.

Daniel Driscoll ⊕ Portland, Maine; Medical School of Maine, Portland, 1885; aged 65; died suddenly, March 29, at Jacksonville, Fla., of angina pectoris.

Edwin G. Proctor, Kane, Ill.; College of Physicians and Surgeons, Baltimore, 1882; member of the Illinois State Medical Society; aged 70; died, April 3.

Rudolph Albert Berneike, Cleveland; Long Island College Hospital, Brooklyn, 1886; aged 68; died, March 26, at the City Hospital, of bronchopneumonia.

Olney Galen Place ⊕ Boulder, Colo.; University of Michigan Medical School, Ann Arbor, 1885; aged 65; died, March 18, of cerebral hemorrhage.

John W. Buxton, Howard, Ohio; Starling Medical College, Columbus, 1883; aged 67; died, March 18, at the Grant Hospital, Columbus, of cholelithiasis.

Peter Eugene M. Goetz, Chicago; Western Reserve University School of Medicine, Cleveland, 1885; aged 62; died, March 28, of chronic myocarditis.

George Washington Baughman, Mansfield, Ohio (licensed, Ohio, 1899); formerly county coroner; aged 72; died, March 30, of bronchopneumonia.

William Mitchell Love ⊕ Chester, S. C.; Medical College of the State of South Carolina, Charleston, 1881; aged 66; died, March 26, of heart disease.

Abdul M. Templeton, Canton, Ohio; Starling Medical College, Columbus, 1889; aged 67; died, March 14, of pulmonary edema and chronic nephritis.

Nathaniel L. MacBride, New York; Hahnemann Medical College and Hospital, Chicago, 1878; aged 71; died suddenly, March 26, of heart disease.

William V. Norris, Corydon, Ky.; Kentucky School of Medicine, Louisville, 1866; aged 82; died, March 17, of influenza and pneumonia.

Francis R. Woodard ⊕ Minneapolis; Rush Medical College, Chicago, 1879; aged 77; died, March 29, at St. Augustine, Fla., of cerebral hemorrhage.

Albert Benton Peck, Knoxville, Tenn.; Vanderbilt University Medical Department, Nashville, 1899; aged 54; died, April 2, of pneumonia.

Virgil Newton Seawell, Faison, N. C.; Washington University School of Medicine, Baltimore, 1868; Civil War veteran; aged 86; died, April 1.

James H. Lathrop, Toledo, Ohio; Toledo Medical College, 1889; aged 69; died, March 28, at the Eastside Hospital, of cerebral hemorrhage.

Fred Anthony Hadley ⊕ Walden, N. Y.; College of Physicians and Surgeons, Baltimore, 1895; aged 63; died, March 23, of heart disease.

Rush Neer ⊕ Paterson, N. J.; Long Island College Hospital, Brooklyn, 1880; aged 76; died, March 19, of carcinoma of the rectum.

Jerry A. Leeman, Pecos, Texas; Kentucky School of Medicine, Louisville, 1876; Civil War veteran; aged 84; died, March 21.

Joe M. Owens, Cross Hill, S. C.; Medical College of the State of South Carolina, Charleston, 1896; aged 54; died, March 22.

Albert E. Norton, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1884; aged 66; died, March 26.

Daniel A. Pelton, Forrest City, Ark.; Barnes Medical College, St. Louis, 1897; aged 60; died, March 29, of angina pectoris.

Charles Franklin Ely, Chicago; New York Homeopathic Medical College, 1876; aged 70; died, April 15, of heart disease.

Lewis L. Baker, Shenandoah, Iowa; Northwestern Medical College, St. Joseph, 1892; aged 70; died, March 26, of heart disease.

Nicholas Green Matthews, Owensville, Mo. (licensed, Missouri, 1884); Civil War veteran; aged 85; died, February 26.

William J. Walker ⊕ Bryan, Ohio; Toledo Medical College, 1898; aged 56; died, March 30, of cerebral hemorrhage.

James Tidwell Raines, Malesus, Tenn.; University of Nashville Medical Department, 1874; aged 66; died, March 28.

Clyde P. Kennedy, Decatur, Ill.; Medical College of Ohio, Cincinnati, 1880; aged 69; died, April 7, of heart disease.

Frank H. Dunlap ⊕ Brawley, Calif.; Kansas City Homeopathic Medical College, 1894; aged 54; died, February 16.

John A. McCrea, Tifton, Ga.; Georgia College of Eclectic Medicine and Surgery, 1885; aged 76; died, March 24.

Irvin R. Mohney ⊕ Brookville, Pa.; Jefferson Medical College of Philadelphia, 1905; aged 51; died, February 11.

Charles Ward Copeland, Fall River, Mass.; University of Giessen, Germany, 1877; aged 73; died, March 30.

John S. Lytle, Dunkirk, Ind.; University of Edinburgh, Scotland, 1880; aged 66; died, March 28.

Emory P. Bryan, Conyers, Ga.; Atlanta Medical College, 1897; aged 57; died, March 23.

Thomas A. Ross, Arkadelphia, Ark. (licensed, Arkansas, 1907); died recently.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

STEERE'S ELIXIR ASPIRIN COMPOUND, STEERE'S ELIXIR AMMONIUM SALICYLATE, NELSON ELIXIR OVARANS, AND ELIXIR DIGITALIN COMPOUND NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. PUCKNER, Secretary.

Steere's Elixir Aspirin Compound, "prepared and guaranteed" by American Laboratories Incorporated, is claimed to contain in each teaspoonful, "Aspirin 2½ Gr., Caffeine Citrated ½ Gr., Rhubarb 1 Gr." and 50 per cent of alcohol. Solutions of acetylsalicylic acid are known to be unstable. The A. M. A. Chemical Laboratory reports that the preparation contains large quantities of salicylic acid, showing that the "aspirin" said to be present was almost entirely decomposed. The liquid possesses an aromatic "bouquet" with a decided odor of ethyl acetate and ignites readily (*alcohol*).

Steere's Elixir Aspirin Compound is unacceptable for New and Nonofficial Remedies because it does not have the composition claimed; because the name is not descriptive of its composition; and because it is irrational to administer a mixture containing acetylsalicylic acid, or its decomposition products, alcohol, caffeine and rhubarb in fixed proportions.

Steere's Elixir Ammonium Salicylate, "prepared and guaranteed" by American Laboratories Incorporated, is marketed with the claim that each teaspoonful represents "Ammonium Salicylate 2½ Grs., Caffeine Alkaloid ¼ Gr., Rhubarb 1 Gr." According to the label it is:

> "Especially serviceable in restoring the Alkaline Reserve where an Acidosis exists as in Broncho-Pneumonia, Influenza, Rheumatism, Colds, &c. . . ."

Steere's Elixir Ammonium Salicylate is unacceptable for New and Nonofficial Remedies because the name is misleading in that it does not correctly declare the potent ingredients; because the recommendations for its use are unwarranted and their inclusion on the label may lead to its indiscriminate use by the laity; and because the routine administration of a mixture of a salicylate, caffeine and rhubarb in fixed proportions is not in the interest of rational therapy.

Nelson Elixir Ovarans, "prepared and guaranteed" by American Laboratories Incorporated, is stated to be "A Pleasant and Palatable Preparation of Viburnum Prunifolium, in Combination with Symplocarpus Foet., Cinnamon, &c., with Aromatics" but no statement of the amount of viburnum prunifolium (black haw) and symplocarpus foetidus (skunk cabbage) is given. According to the label, this preparation of obsolete drugs is thus described:

> "Uterine Tonic and Sedative. Exceedingly valuable in Dysmenorrhoea, Spasms, Flatulency, Convulsions, Cramps, Hysteria, Cholera and Amenorrhoe, &c."

Perhaps in appreciation of the ineffectiveness of the mixture, the label contains the suggestion: "Can be advantageously combined with Bromides, Codea, Morphia, Chloral, &c."

Nelson Elixir Ovarans is unacceptable for New and Nonofficial Remedies because it is a mixture of indefinite composition sold under a noninforming name and with claims that are unwarranted and likely to lead to its ill-advised use by the public.

Elixir Digitalin Compound, "prepared and guaranteed" by American Laboratories Incorporated, is stated to contain 22.5 per cent of alcohol by volume and it is claimed that "Each Fluidrachm Contains:—Digitalin, 1-100 gr.; Nitroglycerin, 1-100 gr.; Strychnine Sulphate, 1-50 gr." No information is contained on the label or in the circular letter sent to physicians in regard to the form of "digitalin" contained in the preparation nor is there any assurance (other than the statement that the preparation is "prepared and guaranteed" by the firm), to show that the unstable nitroglycerin is present in the product that reaches the patient in the amount claimed on the label. Tests carried out in the A. M. A. Chemical Laboratory showed that the specimen sent to the Council was practically devoid of this potent ingredient. This mixture is:

> "Recommended in fevers or low condition of the system from any cause. Especially indicated in Collapse requiring immediate stimulants after shock or surgical operation "

A miniature reproduction of a new poster just issued. This is one of forty educational posters prepared and issued by the Bureau of Investigation of the American Medical Association. The original posters are 22 inches by 28 inches, and sell for twenty cents each.

The word "Digitalin" has been applied to many different substances, and it is almost meaningless unless qualified, *e. g.,* "German" Digitalin, "French" Digitalin, or True Digitalin. The name should be applied only to the last mentioned, of which we do not know the dose, because it is absorbed poorly from the gastro-intestinal tract. Certainly, doses of 1/400 of a grain repeated several times a day are not sufficient to induce the typical effects of digitalis, and Eggleston says (*Arch. Int. Med.*, 1915, **16**, p. 1) that True Digitalin is unsuited for therapeutic use by oral administration. The nitrites have been used as "cardiac tonics" but, as Cushny says (Pharmacology and Therapeutics, 8th edition, 1924, page 406) any benefit from their use in cardiac conditions arises from their causing decreased resistance to the flow of blood, and it is well known that they (including nitroglycerin) cause dilatation of the vessels, and consequent fall of blood pressure. There can hardly be a more irrational procedure than to use a vaso-dilator, such as nitroglycerin, in collapse or shock in which the blood pressure is exceedingly low.

The action of Digitalis is far more lasting than that of nitroglycerin, hence their combination in fixed proportion in a mixture is irrational. Strychnine can possibly have some therapeutic value in shock, but this is problematic. It should be used alone, if at all, and only as specifically indicated.

Elixir Digitalin Compound is unacceptable for New and Nonofficial Remedies because its composition is uncertain; because the name is not descriptive of its composition; and because it is an irrational combination marketed with claims that are unwarranted.

Correspondence

"THE BASAL METABOLISM OF MAN IN THE TROPICS"

To the Editor:—My attention has been drawn to Dr. E. F. Du Bois' comments on "Basal Metabolism in Health and Disease." I have also read with interest Dr. S. S. Cohen's letter (The Journal, Jan. 28, 1922, p. 297) and your editorial comment (Dec. 31, 1921).

I have been determining the basal metabolic rate in young Bengalese students (aged 22 to 27 years) for some time. Using the Douglas bag and Haldane gas analysis apparatus, I have so far studied fifteen medical students of our college. They show an average basal metabolic rate 9 per cent lower than the generally accepted standards at an average room temperature of 27 C.

It would thus appear that metabolism is somewhat decreased in tropical or semitropical countries, though my findings are not so striking as those of de Almeida.

It may be mentioned that the urea nitrogen, nonprotein nitrogen, creatinine and cholesterol contents of the blood in Bengalese are lower and the uric acid content is higher than the accepted standard values (*Calcutta M. J.*, May, 1925; October, 1925).

H. N. Mukherjee, Calcutta.

GERMANISMS IN THE DUTCH LANGUAGE

To the Editor:—In my copy of The Journal, February 20, I detected something under the headline "Netherlands" that I feel bound to correct. Our language is getting spoiled more and more by Germanisms of various kinds. But we are not Germans yet. So if you haven't got a perfectly adequate English word for the German "Krankenkasse," your correspondent should have used the Dutch "Zichenfonds," at the same time conveying its meaning of a certain form of insurance in case of sickness. And the literal translation "Sickfund" or Fund for the Sick would have been better than the German expression.

It is Prof. van der Valk, not v. den Valk, who was appointed head of the new dermatologic clinic at the Government University, Groningen.

I should like being able to subscribe to your correspondent's opinion of the excellent results of Dutch instruction of the masses in hygiene. I had full opportunity to study the utmost opposite during an epidemic of scarlet fever and in some more casual facts, especially concerning quackery and the advertising of quackery manufacturers.

L. W. Schut, M.D., Vlieland, Netherlands.

DIGITALIS MEDICATION

To the Editor:—In his studies to determine the clinical value of parenteral digitalis medication, Pardee used only the electrocardiogram, a method which has not yet been perfected satisfactorily so as to permit definite conclusions from a therapeutic standpoint.

We have known for some time that relatively high doses of digitalis are well borne when given intravenously. It is also well known, and especially Sahli pointed this out, that small doses will give as good results as large ones. Sahli finds it entirely unnecessary to go beyond 4 cc. (of digalen); in most cases, 2 cc. is fully sufficient to obtain the full therapeutic action. Kottman also showed that large doses (of digalen) are well borne, but he states explicitly that from 1 to 3 cc. will give the same clinical effect. In other words, Kottman and others showed that the upper margin of safety is high, that the zone between the clinically effective and the toxic dose is wide. Observations with other injectable digitalis preparations gave similar results, which demonstrates the relatively small toxicity of digitalis bodies when given intravenously. This cannot be said for strophanthus.

The fact that continued oral administration of digitalis brings about stronger effects than a single injection is in correlation with our newer conceptions of the cumulative action. Gradually some digitoxigenin accumulates, which is not the case with intravenous injections and the rapidly following elimination *en masse*. Furthermore, digitalis acts partly on the sympathetic system, and we know that the administration, for days or weeks, of accelerating or inhibiting substances may bring about reactions in the sympathetic system (sometimes a complete reversal of action) which we can never get even with very large single doses.

In my belief, what the author considers a simple question of dosage is a far more complicated problem. His conclusions may actually prove dangerous, when applied by inexperienced practitioners.

Prof. Max Cloetta, Switzerland.

Department of Pharmacology,
University of Zurich.

[The letter of Professor Cloetta was referred to Dr. Pardee, who replies:]

To the Editor:—I was much interested to receive the criticism of my recent paper on digitalis medication. The critic is certainly quite right in saying that the method of testing digitalis is one which has not yet been perfected so as to permit definite conclusions from a therapeutic standpoint. On the other hand, I have had considerable occasion to check it and I have found it satisfactory.

I am not sure as to what Sahli and Kottman meant when they referred to full therapeutic action and clinical effect. It is not likely that they meant the same thing that I would mean if they have obtained it after 2 cc. or 3 cc. of digalen. I am unfamiliar with and cannot find the literature to which reference is made. My own experience shows that there is a great difference between the activity of 30 minims and 120 minims when given intravenously in each case. I do not find much difference between 30 minims intravenously and 30 minims by mouth, except in the rate of onset of the action. He refers to rapid elimination following intravenous injection. This is not proved as far as I know and I do not believe it occurs. My experience with the intravenous method since the publication of the article has led me to believe that what was said there will stand. An article showing the effects of therapeutic administration of these intravenous doses will appear shortly. It is certainly true that large intravenous doses as well as large doses by mouth may actually prove dangerous when applied by inexperienced practitioners. This is regrettable but cannot be avoided. It should not stand in the way of the wider dissemination of knowledge of the proper dose of digitalis.

I confess that I was greatly surprised at the result of this experimental work with intravenous digitalis preparations. I was slow to accept the facts stated in my conclusion, but was forced to do so; and, as I have said, subsequent usage has quite borne out my conclusion.

Harold E. B. Pardee, M.D., New York.

"CONTROLLING THE ODOR AND TASTE OF ARSPHENAMINE"

To the Editor:—In The Journal, March 20, page 840, I read with much interest Dr. J. H. Stokes' short article on "Controlling the Odor and Taste of Arsphenamine," in which he states that he allows a strong wintergreen or clove wafer to dissolve on the patient's tongue during the injection.

I frequently have patients complain of the same peculiar odor and taste while receiving an intravenous injection of arsphenamine, particularly neo-arsphenamine, and I have always found that this could be almost entirely relieved by smelling a little cotton well moistened with bay-rum. The reason why I used bay-rum is that when looking about for something with a decided odor I happened to have some handy in my office, and it has a peculiar penetrating odor. I have been using bay-rum for this purpose for the last ten years and have been well satisfied with the results, although I have never reported its use.

C. J. Broeman, M.D., Cincinnati.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ALBUMOSURIA

To the Editor:—1. Is the prognosis of albumosuria necessarily unfavorable? 2. Are all cases showing albumose in the urine hopeless? Our textbooks speak of Bence-Jones albumosuria, and give the prognosis as being fatal within two years. The Bence-Jones albumosuria occurs in myelomas, cancer and leukemia. They also mention albumosuria in connection with pneumonia, pregnancy, scurvy and intestinal indigestion. But in giving the prognosis they state that it is of grave significance, and runs a fatal course within two years. The literature is very meager, and we do not know whether the cases in which it occurs in connection with pneumonia necessarily result fatally or not. And likewise for the cases associated with pregnancy, indigestion, etc. 3. I have under my care at this time a young woman of 17, married, and about eight months advanced in her first pregnancy. The urine shows a large quantity of albumosuria: she recently had the greatest percentage of albumin that I have ever witnessed in any one's urine (by volume). We have eliminated the albumin, and now have a very decidedly large amount of albumosuria in the urine. Her face was swelled, but the swelling has disappeared under treatment. Please give me all the information you can reasonably in regard to the significance of albumosuria in the urine in cases other than those called Bence-Jones albumosuria.

J. W. Yankey, M.D., Sylvia, Kan.

Answer.—1. No.

2. No.

3. Deutero-albumose is the type usually found. It differs from the Bence-Jones protein, which is probably a true albumin. Albumosuria is observed in a great variety of conditions, and may occur in association with albumin, the mixed albuminuria of Senator. It does not arise in the kidney but is evidence of infection, irritation, functional disturbance, and the like, in various organs of the body. Large accumulations of pus are particularly prone to cause albumosuria until they have been evacuated or absorbed. Unless it should occur in some condition which of itself will lead to a fatal issue, it is of little prognostic significance.

DIPHTHERIA ANTITOXIN—EPINEPHRINE IN INSULIN HYPOGLYCEMIA

To the Editor:—1. Is it safe to use diphtheria antitoxin intravenously? What are the indications and contraindications? 2. In hypoglycemia induced by overdosage of insulin, will epinephrine cause a liberation of glycogen from the liver, with benefit to the patient? Please do not publish my name.

M.D., Galveston, Texas.

Answer.—1. Diphtheria antitoxin can be given intravenously almost always when it can be given subcutaneously. It is particularly of value in late, advanced cases. Park reports that, given intravenously, 5,000 units is as valuable as 20,000 given subcutaneously. The contraindications are the same as for subcutaneous injection. Anaphylaxis, which occasionally is the cause of severe symptoms, may be looked for in those susceptible to horse serum injection. This applies particularly to patients who at some previous time have received horse serum injections. In these cases it is advisable to give a subcutaneous injection of a few drops of serum. If no reaction occurs, the full dose can be given two or three hours later.

2. Wilder and his associates (*J. Metab. Research* **2**:701 [Nov.-Dec.] 1922) state that epinephrine may be used to combat insulin hypoglycemia in man. They note the relatively short duration of its effect, but emphasize the necessity of administering carbohydrates immediately after the patient is able to swallow. Macleod and Campbell (Insulin and Its Use, 1925, p. 102) do not favor its use. Since the glycogen stores are already depleted in emaciated patients, the amount of glucose set free by epinephrine may be too small to relieve the hypoglycemia. Since it also increases the heart work, the results may be most serious if no glycogen stores are available.

BARIUM SULPHATE FOR CYSTOGRAMS

To the Editor:—Some time during the past year I read in the French journal *Urology* the statement that they were using a barium preparation in the bladder for cystograms. At the recent meeting of the Radiological Society at Cleveland, mention was also made of this fact. The preparation, however, was made after a certain fashion, the substance being exceedingly fine and homogeneous. Will you kindly tell me the method of preparing this medium for cystographic work?

J. E. B. Ziegler, M.D., Eau Claire, Wis.

Answer.—The substance employed was a very fine suspension of barium sulphate, utilized in a manner similar to opaque washings. The barium sulphate is eliminated by micturition or vesical lavage in a short time. Edmund Papin has reported that it is used without inconvenience and is well tolerated (Société française d'urologie, March 16, 1925; *J. d'urol.* **19**:343 [April] 1925). A 40 per cent suspension of fine barium sulphate is being prepared in this country and is under consideration by the Council on Pharmacy and Chemistry.

DOSE OF COD LIVER OIL

To the Editor:—I am anxious to get some definite data as to the amount of cod liver oil necessary for normal infants, preschool children, school children and adults. I find that the statements differ so in regard to pure cod liver oil that I am writing to ask you what is the amount which you consider necessary for normal individuals mentioned and on what you base your conclusions. Has there been sufficient work along this line to give us a scientific backing for the amounts prescribed?

Helen Monsch, Ithaca, N. Y.

Answer.—The experimental data concerning the use of cod liver oil in the prevention of rickets have been confined almost exclusively to rats. Some work has been done on chickens. Harry E. Dubin (*Am. J. Dis. Child.* **30**:72 [July] 1925) writes that, with a dose of 7 mg., rats on the Pappenheimer zucker diet D, which consists of patent flour, 80.9 Gm., egg albumin, 10 Gm., butter fat, 5 Gm., and salts, 4.1 Gm., developed slight rickets. He says that the minimal dose varies both with the potency of the oil and with the type of diet used. While a less than minimal dose for a rat weighing 49 Gm. was 7 mg. of cod liver oil daily, other animals required 14, 21 or 28 mg. of cod liver oil to prevent rickets.

Howland and Kramer (*Am. J. Dis. Child.* **22**:105 [Aug.] 1921) showed that in a 35 months old baby, the healing of rickets determined by roentgenogram occurred after the administration of 2 cc. of cod liver oil given twice a day for two months. They found that from 2 to 4 cc. of cod liver oil, given three times a day for a period as short as three weeks or as long as ten weeks, caused active healing of rickets, as shown by roentgen-ray tests.

Martha M. Elliot (The Journal, Aug. 29, 1925, p. 656) found that from 10 to 20 drops of cod liver oil given twice a day was sufficient to protect young infants against the development of rickets, though, on the other hand, it was found that infants who were kept on this dose for several months tended to show roentgen-ray evidence of early rickets. From her experience she found it necessary in order to protect against this disease to, give one-half teaspoonful twice daily before the first month. During the second month the dose is gradually increased to 1 teaspoonful twice a day. If the roentgenogram shows any increase in the rachitic process, the dose is increased to 1½ teaspoonfuls or even 1 dessertspoonful before the end of the third or fourth month.

These doses have been worked out by the observations of a number of workers, who have checked their results by roentgen-ray examination of the bones.

There are no available data about the dosage of cod liver oil for preschool children, school children or adults. In the period after infancy, rickets does not commonly occur, and cod liver oil is administered for its effect in promoting growth and development and to supply an accessory food substance which is twenty times as potent as butter fat in the prevention of keratomalacia.

HYPERCALCEMIA

To the Editor —In The Journal, March 13, page 803, appears a reply to a query of Dr Joseph Halton, Sarasota, Fla, stating that as yet hypercalcemia has never been demonstrated after oral administration of calcium salts in any quantity and for any length of time. In the light of recent investigations, this statement is erroneous

Luckhardt and his collaborators (*Am. J Physiol.*, 1923-1925; *Proc. Soc Exper Biol. & Med.*, 1923-1925) found that calcium lactate given orally to tetanic dogs relieved symptoms, provided it was given in doses of at least 1 5 Gm. per kilogram of body weight daily.

Salvesen and his associates (*J. Biol Chem* **60**: 327 [June] 1924) observed a serum calcium increase in one of two dogs which received 7 5 Gm of calcium chloride by mouth

Boothby (*Endocrinology* **8**: 662, 1924) succeeded in controlling the symptoms of strumaprivic tetany in the human species by giving calcium lactate in 4 Gm. doses every three hours, day and night.

The foregoing shows directly and indirectly that calcium salts may be absorbed, when given orally, in quantities sufficient to increase the blood calcium In my own observations (*J. Biol. Chem.* **45**: 783 [Oct] 1925) I found that Luckhardt's minimum dosage of 1 5 Gm. of calcium lactate per kilogram of body weight was also the smallest dose that would assure induction of hypercalcemia. Doses of one half this amount induced an increase in serum calcium in dogs, but not consistently. Luckhardt has told me that in recent observations of his he has confirmed my findings

It is not my purpose to discuss the rationale of oral calcium therapy, but merely to call attention to the fact that hypercalcemia may be induced by oral administration of large amounts of certain calcium salts

A. M. Hjort, M.D., Detroit.

TREATMENT OF ALOPECIA

To the Editor —Will you kindly help me out? I have a patient with alopecia universalis The patient began to lose hair about August, 1925, and at the same time stopped menstruating The menses are still suppressed She is 22 years of age, she has one child in good health, the Wassermann reaction is negative, she is not neurasthenic, anemic or diabetic My treatment so far, over a period of about two months, has been quartz light twice weekly, second and third degree burns, with local applications of:

Tinc cantharides .... 24 cc.
Tinc. capsici .... 3 cc
Olei ricini .... āā 3 cc.
Bay rum, q. s .... ad 180 cc.

with no result. Also ovarian and thyroid

H W. Nilssen, M D, Chicago.

Answer —The patient has apparently a case of alopecia areota totalis associated with an endocrine disturbance. The treatment of the universal types of alopecia areata is very unsatisfactory. A sparse regrowth of delicate hairs can sometimes be secured by local therapy with quartz light and stimulants such as Cutler's solution (equal parts of phenol [carbolic acid], tincture of iodine and chloral hydrate). This regrowth is usually not permanent. In addition, arsenic may be used for its tonic effects.

TREATMENT OF RINGWORM

To the Editor —I should like to get some specific treatment outlined through The Journal for the cure of a form of ringworm (cow itch), which is quite common throughout this section of the country It is very common on young cattle and is easily transmitted to people who feed or handle these cattle. It assumes a typical form of ringworm, and is most obstinate to treat when affecting the beardy part of the face Ordinary parasiticides seem to do little or no good in treating this malady.

B E Reeves, M D, West Jefferson, N. C.

Answer —Ringworm contracted from cows may be either of the superficial type, the ordinary tinea circinata, or of the deeper seated type of ringworm infection of the beard. The former variety usually responds readily to the parasiticides ordinarily employed in the treatment of ringworm. The deep seated ringworm infection of the beard is very resistant to treatment. The beard should be kept closely clipped, and epilation carried out either by the use of forceps or roentgenotherapy. The entire bearded region should be sponged twice daily with a solution of 1 per cent mercuric chloride in alcohol, and the affected parts rubbed with a 10 per cent oleate of mercury ointment. Another useful application is an iodized fat made by dissolving 12 per cent iodine crystals in goose grease, this ointment to be rubbed in daily until some reaction is secured, when it should be employed less frequently. Mercurial preparations should not be used on the face at the same time that iodine is employed. Cure ordinarily requires a considerable time, and not infrequently epilation by means of the roentgen ray is the only successful method.

Book Notices

KIDNEY DISEASE. From the Physician's Viewpoint. By Rolfe Floyd, M.D., Junior Attending Physician and Pathologist at the Roosevelt Hospital, New York. Cloth. Price, $2.50. Pp. 181. New York: James T. Dougherty, 1926.

In his introduction, the author gives a clear and concise survey of the problems encountered in discussing medical renal diseases. In the chapters on classification, he records historical material that may be of great value to the medical philosopher and historian but hardly is apt to arouse the interest or answer the demands of the practicing physician. In the chapter on renal functions, one finds an excellent presentation of the fundamental facts to be considered in qualifying the task of the kidneys, but the author fails to present a workable theory of renal function, though a great many leading clinicians have offered such news, based on clinical evidence in preference to the results of animal experiments. One also misses the desirable emphasis to be laid on one of the most essential features of the renal activity—the elasticity of function to adjust itself to the variations in the offerings of the metabolic end-products. The author is in error in stating that all the current functional theories are based on the conviction that the tubules alone represent the functional units. Many authors agree that it is the glomeruli that excrete the urinary water and the nitrogen compounds, while the tubular system produces the remainder of the urinary solids. The chapter on uremia is characterized by a full presentation of the clinical facts, and excels in sound reasoning. In dealing with renal dropsy, the author gives full recognition to the modern concept, that the intermediate structures play an important part in the production of this clinical phenomenon. The author repudiates the concept and term nephrosis in Volhard's sense, but quotes instances in which, during necropsy, only degeneration of the tubular epithelium was found without any pathologic involvement of the glomeruli. It is satisfactory to note that in dealing with the renal functional tests the author reduces the popular overestimation of the value of the color tests to the proper proportions. One misses, though, an enumeration of the precautions to be employed in order to guarantee a proper evaluation of the results gleaned from the various functional capacity tests. The critical ability of the author cannot be better characterized than by quoting the closing lines of the chapter: "Meantime let us be more particular about the terms we employ and never try to warp nature with them to our own undoing." The chapter on treatment is inadequate, since the author attempted the impossible task of covering the subject in ten pages.

DAS WACHSTUM DES KINDES. Von Prof. Dr. Eugen Schlesinger, Städtischer Fürsorgearzt in Frankfurt a. M. Paper. Price, 6 marks. Pp. 128, with 8 illustrations. Berlin: Julius Springer, 1926.

Schlesinger has reviewed the literature on the growth of the child. His point of view is that of the school physician; hence his observations are concerned chiefly with measurements, tables and systems of procedure. Some chapters are too mathematical to interest the practicing physician. On the other hand, the author's experience during the World War, when he had the opportunity of observing the effect of undernutrition on a large scale, makes chapters of considerable interest. While more a summary of the literature than an exposition of the author's own studies, the book offers a number of interesting conclusions. No procedure for the mathematical determination of growth is entirely satisfactory. The determination of change in length is of more constant value than that of body weight. The characteristic separating the human from all other animal species is the second period of accelerated growth starting at puberty. There is no constant relation between increase in length and in weight. For instance, in the preschool age children gain relatively more rapidly in length than in weight, while during the later school years the reverse is true. There are also changed relations during the different seasons. The influence of any especial food on growth is not definite. Qualitative or quantitative undernutrition affects growth, depending on the duration and severity of the hunger and, above all, on the age of the individual. Should extreme hunger occur in the first few weeks of life, as a rule normal averages will never be reached. Weight is affected sooner and more decidedly than length. The undernutrition in the war resulted in manifest changes as regards both weight and length. During the reparation period, the resumption of the length growth was startling, and greatly overbalanced the weight. The book contains a large amount of material and should appeal to those having a technical and scientific interest in the mathematical determination of body growth.

DISEASES OF THE EYE. A Manual for the Practitioner. By Henry Kirkpatrick, M.B. Cloth. Pp. 132, with 28 illustrations. Calcutta: Butterworth & Co., 1925.

The preface states that "the object of this book is to enable the general practitioner, especially one practicing in remote parts, to render serviceable first aid to such sufferers from diseases of the eye as he may encounter in the course of his work." In every respect the book lives up to this statement, and it furnishes a veritable mine of information for the medical man who has not specialized in ophthalmology. The descriptions are clear cut and in simple language; the word pictures are ample, but not verbose; and the curative measures proposed are such as lie within the power of administration by any medical man. Unnecessary technicalities are avoided, so that the general man is not confused by inconsequential points of differential diagnosis. Of course, ophthalmologists will differ with the author on certain points, for example, the influence of an uncorrected error of refraction on the development of a hordeolum or even a chalazion; but, in the main, he enunciates truths. A limited amount of space is given to a brief description of the technic of certain necessary operations that a man in a remote district might be called on to perform. These descriptions are brief and to the point, but sufficiently clear. It is interesting to note that his choice of operations was undoubtedly influenced by his long residence in India and the character of the work that he was there forced to do. The last seven pages are devoted to an ophthalmic pharmacopeia in a readily usable form. The quality of paper and the printing of the book leave a good deal to be desired, but this is soon forgotten in a consideration of the value of the text.

PRINCIPLES OF PHARMACY. By Henry V. Arny, Ph.M., Ph.D., F.C.S., Professor of Chemistry in the College of Pharmacy of Columbia University. Third edition. Cloth. Price, $8 net. Pp. 1078, with 289 illustrations. Philadelphia: W. B. Saunders Company, 1926.

This book is written primarily for students of pharmacy, but it contains much material with which physicians should be familiar. The present edition is based on the new tenth revision of the U. S. Pharmacopeia. It covers practically the entire field of pharmacy, including the chemistry, physics and even botany of drugs.

OPERATIVE CYSTOSCOPY. By E. Canny Ryall, F.R.C.S., Founder of and Senior Surgeon to All Saints' Hospital for Genito-Urinary Diseases, London. Cloth. Price, $25. Pp. 47, with 670 illustrations. St. Louis: C. V. Mosby Company, 1925.

Up to now the beginner in operative cystoscopy had to rely on self-tuition as the only possibility in instruction. This book answers the cry for practical study and embodies the results of long and progressive work. Its publication will prove of the greatest value to the budding specialist. It is the first volume of its kind that has been published in any language, and it fills a great gap in the teaching of intravesical procedures. The text is concise; if any adverse criticism could be given, too concise; yet it is clear, to the point and comprehensive in its subject matter. The pages on local anesthesia are interesting, but one could hardly follow the author in his indiscriminate use of cocaine; American urologists have almost entirely discarded cocaine in favor of procaine. The various points in technic for the removal of ureteral calculi are most ingenious and might well be tried and added to those in general use. The author has devised many instruments which are appealing in the logic of their employment and at the same time simple in their manipulation in the hands of the experienced cystoscopist. Cystoscopic litholapaxy, although not entirely new, is so well and thoroughly illustrated as to make the procedure a relatively simple one. The many plates on diathermy and high frequency in their various uses and their various progressive stages of treatment make probably the most valuable group in this large volume. The subject is dealt with in detail, and if for no other reason, argues strongly for the book as an adjunct to the urologist's armamentarium. The text on this subject is given in full and practical detail. Each colored plate throughout the book is an artistic painting true to the pathologic picture it portrays. Their number is legion and the greatest value in them are the progressive stages of the various treatments and their results. The book will be invaluable to the beginner in operative cystoscopy, and might well be used for reference by those more experienced.

PLASTIC SURGERY OF THE NOSE. By J. Eastman Sheehan, M.D., F.A.C.S., Associate Surgeon and Lecturer to the International Clinic of Otorhinolaryngology and Facio-Maxillary Surgery, Paris. With a Foreword by John F. Erdmann, M.D., F.A.C.S., Professor of Surgery, New York Post-Graduate Medical School and Hospital. Cloth. Price, $10. Pp. 249, with 186 illustrations. New York: Paul B. Hoeber, Inc., 1925.

This book is based on the author's six years' experience in plastic surgery. About half of the text is devoted to cosmetic correction of nasal deformities. Since plastic surgery is really not a new branch of surgery, but dates from the time of Celsus and Tagliocozzi, we do not look for anything triumphantly new. Naturally, since the development of this field in the war, we may expect a great improvement in the way of modifications and technic, but the fundamental principles remain the same. The author makes a plea for professionalism instead of amateurism in the field of plastic surgery, and this point is well taken; for it should be stressed that work in this field should be in the hands of those who have made a special study of it. One must take exception to the author's feeling that the patient is continuously under observation by others and his failure to bring out that in the greater number of cases the patient is under the observation of himself. The author has divided the text into fifteen chapters titled as to his own inclination, featuring the columellar incision as an original operation. It is not well understood just what the reason was for giving the deflection of the septum a chapter in such a book, particularly as no relation of the septal deformity to plastic surgery of the nose is indicated. The technic is simply outlined and illustrated, but more should have been said about the unusual results and complications, as the simplicity of words may lead to a light-hearted attempt on the part of the reader to follow the methods, wholly unaware of the pitfalls. However, the author has in mind the abuse of this type of surgery when he says, "I would like this handbook to exemplify the conviction that in even the simplest cases of repair, whatever in surgery is worth doing is worth doing as well as it can be done and that it ought to be attempted only by those whose knowledge and training have been such as to justify the undertaking."

GRUNDRISS DER HEILPADAGOGIK. Von Dr. Phil. Theodor Heller, Direktor der heilpadagogischen Anstalt Wein-Grinzing. Third edition. Paper. Price, 15 marks. Pp. 765, with illustrations. Leipsic: Wilhelm Engelmann, 1925.

This textbook on nervous and mental disorders of children, with especial reference to the problems of special pedagogy, is a thorough review of the German literature (with scant knowledge of the vast American literature on the subject) and contains a valuable bibliography. Many chapters are unnecessarily long, containing classification after classification and too numerous definitions. The first 500 pages comprise a textbook on mental deficiency with three chapters on special pedagogy and institutional training. Part II (about 300 pages) deals with nervous and psychopathic children, their pedagogic therapy and prophylaxis. It is as complete as part I and includes a critical summary of the contributions of the psychanalysts. In his introduction, Heller outlines his policy in regard to the mental problems that belong legitimately to the heilpedagogue (therapy teacher). The "therapy pedagogue" should be utilized wherever a specialized type of teaching is required, as in the deaf, blind and feebleminded. At first his rôle was limited to feeblemindedness. Now, says Heller, it extends to all abnormal children, in whom the abnormal function can be directed by "individually applied developmental conditions." This would appear to include everything in child psychiatry except the rare cases of juvenile psychoses. Heller is quite insistent on this point: "Not only in disturbances of intelligence but also in the affect and volitional life are the services of Heilpädagogie required." From the medical point of view, the services of the special educator are limited to the purely pedagogic phase of nervous or mental disease. To take an example from organic medicine, the diagnosis of deafness and its medical treatment is performed by the physician, the teaching of lipreading by the heilpedagogue. Such methods of therapy as have evolved out of the physician's particular experience and diagnostic skill can safely be entrusted to him alone and are part and parcel of his general armamentarium. This includes hypnosis, psychanalysis, and other forms of specialized psychotherapy. Certainly the educator and the psychologist are coming more and more into fields previously considered the domain of the physician. As long as the patient profits, so much the better. The danger lies chiefly in attempting to include cases for which they have no training.

MANUAL OF HYGIENE AND PUBLIC HEALTH: A Text Book for Medical and Public Health Students. By Jahar Lal Das, D.P.H. Offg. Asst. Director of Public Health, Bihar & Orissa. With an introduction by Lieut.-Colonel W. C. Ross, M.B., Ch.B., D.P.H., Director of Public Health, Bihar and Orissa. Cloth. Price, 10 shillings, 6 pence net. Pp. 634, with 105 illustrations. London: Butterworth & Co., 1925.

The progress of public health in India is of interest to all the world. Dr. Das' book appears about a year after the fourth edition of a similar volume in which he collaborated. The subjects usually included in a manual on public health are discussed. On the whole, these discussions are well written; but in some cases details of laboratory procedures are so fully given that the reader loses the more fundamental aspects of the problems. The temperature for milk pasteurization is given as 167 F. This is some 20 degrees higher than American practice, and such a temperature would be impracticable in this country. It is of interest to note that the infant mortality rate in Calcutta for 1921 was 330, and for 1922, 287. The author believes that early marriages and improper attendance during labor are largely responsible for this excessive rate. The expectation of life in India is also far below that of European countries: 22.59 at time of birth in India, as against 46.04 for England in 1911. The book contains much material on foods, but perhaps this is justified by local conditions. A fuller discussion of the infant welfare problem would be of interest.

PATHOLOGY OF THE MOUTH. By Frederick B. Moorehead, M.S., D.D.S., M.D., Dean of the Department of Oral Surgery and Pathology, College of Dentistry, University of Illinois, and Kaethe W. Dewey, M.D., Assistant Professor of Pathology, College of Dentistry, University of Illinois. Cloth. Price, $7 net. Pp. 640, with 213 illustrations. Philadelphia: W. B. Saunders Company, 1925.

The authors state that they have treated the subject of the mouth in both its local and its interdependent relations, its primary and secondary lesions, and that while there is a scattered literature on the subject, this is the first time it has been treated in its entirety in a single volume. This is true so far as publications in English are concerned. The method of treatment is such that a better title or subtitle would have been: Etiology, symptomatology, relationship and pathology of the diseases of the mouth. Part I deals with general diseases; part II, with tumors. The best chapter is the one about giant cell tumors, and one of the weaker chapters is the one concerning pyorrhea. It would appear that the authors had not been able to suppress their own interests for the sake of a better balanced text. A bibliography of 505 titles is appended; while this is more elaborate and more nearly complete than those found in most domestic dental textbooks, it is poorly arranged and there are numerous discrepancies between it and the text. The accuracy of some statements may well be questioned as: "Angina syphilitica is the most frequent form of secondary syphilis of the mouth." and "Uremia favors the development of pyorrhea." The arrangement in many places could have been improved; e. g., mixed cell tumors are discussed in three different chapters. One wonders why the necrosis of the jaw bones due to radioactivity was not discussed in either chapter 8 or chapter 24. The illustrations, on the whole, are well chosen and technically excellent, though a few either do not represent at all what the legends indicate or represent them unsatisfactorily, as figures 10, 20, 43 and 151. Credit has been acknowledged to individuals for material used in illustrations in certain cases in which it would have been in better taste to credit the institutions from which the specimens were borrowed. The volume deserves careful study by all those interested in pathologic conditions of the mouth.

Man: His Making and Unmaking. By E. Boyd Barrett, M.A., Ph.D. Cloth. Price, $2.50. Pp. 269. New York: Thomas Seltzer, 1925.

This is a book of rather loose structure in which a multitude of assertions are made with a lack of relating background. There is a religious tinge to the general atmosphere of the book, and yet the author tells the church that an effort must be made to understand man instead of expecting blind obedience. The personality chapters at the end of the book are much its best features. However, there is merely a suggestion of what the problem is in each case, with no thorough analysis.

Die Ursache des Carcinoms. Von Prof. R. P. Van Calcar. Aus dem bacteriologisch-hygienischen Laboratorium der Universität Leiden. Paper. Pp. 66, with 45 illustrations. Leiden: S. C. Van Doesburgh, 1926.

This is an attempt to revive the theory that cancer represents a symbiosis of protozoa and cancer cells. The author believes that achylia is a predisposing factor. The arguments advanced are not convincing to those not committed to this theory of the causation of cancer.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Die Schädigungen der Haut durch Beruf und gewerbliche Arbeit. Herausgegeben von Obermedizinalrat Dr. Karl Ullmann, Privatdozent an der Universität in Wien. In Gemeinschaft mit Dr. Moriz Oppenheim, Primararzt und Professor an der Universität in Wien, und Obermedizinalrat Dr. J. H. Rille, o. Professor an der Universität in Leipzig. Band II, Lieferung 5-8. Paper. Price, 24 marks. Pp. 384, with 98 illustrations. Leipsic: Leopold Voss, 1926.

Industrial skin diseases due to formaldehyde and coal tar derivatives.

Lehrbuch der speziellen Pathologie und Therapie der inneren Krankheiten. Für Studierende und Aerzte. Von Professor Dr. Med. Adolf Strümpell, Direktor der medizinischen Klinik der Universität Leipzig. Erster Band. Von Professor Dr. Med. et Phil. Carly Seyfarth, Assistent an der medizinischen Klinik der Universität Leipzig. Twenty-fifth edition. Paper. Price, 50 marks. Pp. 872, with 147 illustrations. Leipsic: F. C. W. Vogel, 1926.

Twenty-fifth edition of standard German textbook.

An Elementary Course in Tropical Hygiene. Part II. By Mary G. Blacklock, M.B., B.Sc., D.T.M., Lady Medical Officer, Sierra Leone, West African Medical Service. Preface by Andrew Balfour, C.B., C.M.G., M.C., Director, London School of Hygiene and Tropical Medicine. Paper. Price, 2 shillings, 6 pence net. Pp. 108, with 33 illustrations. London: John Bale, Sons & Danielsson, Ltd., 1926.

Part two of popular book on tropical hygiene.

Buchanan's Text-Book of Forensic Medicine and Toxicology. By John E. W. MacFall, M.D., D.P.H., M.B., Professor in Forensic Medicine and Toxicology, University of Liverpool. Ninth edition. Cloth. Price, $5. Pp. 445, with 57 illustrations. New York: William Wood & Co., 1925.

Ninth edition of standard British work based on British medicolegal procedure.

Trial of the Seddons. Edited by Filson Young. Second edition. Cloth. Price, 10 shillings, 6 pence net. Pp. 420, with 3 illustrations. Edinburgh: William Hodge & Co., Ltd., 1925.

Report of a famous British murder trial in which the Marsh test for arsenic played the leading rôle.

Trial of Dr. Pritchard. Edited by William Roughead, Writer to the Signet. Cloth. Price, 10 shillings, 6 pence net. Pp. 343, with illustrations. Edinburgh: William Hodge & Co., Ltd., 1925.

Dr. Pritchard, quack, murders many with aconite.

Facts on the Heart. By Richard C. Cabot, M.D., Professor of Medicine and of Social Ethics at Harvard University. Cloth. Price, $7.50 net. Pp. 781, with 163 illustrations. Philadelphia: W. B. Saunders Company, 1926.

Clinical records of 1,906 cases of heart disease, with general consideration.

Trial of Oscar Slater. Edited by William Roughead. Second edition. Cloth. Price, 10 shillings, 6 pence net. Pp. 306, with illustrations. Edinburgh: William Hodge & Co., Ltd., 1925.

A murder trial in which every aspect of the psychology of personal identification was considered, reported by a master of criminal reporting.

Psychotherapy. Mental Elements in the Treatment of Disease. By Edward Wyllys Taylor, James Jackson Putnam Professor of Neurology in Harvard University. Harvard Health Talks, 14. Cloth. Price, $1. Pp. 53. Cambridge: Harvard University Press, 1926.

Well written historical review, with emphasis on need of scientific medical education on mental healing.

Bacteriology and Applied Immunology for Nurses. By Robert A. Kilduffe, A.B., A.M., M.D., Director, Laboratories, Atlantic City Hospital. Leather. Price, $2. Pp. 252, with 79 illustrations. Milwaukee: Bruce Publishing Company, 1926.

Nurse's textbook with much information that a nurse need not know.

Die chirurgische Behandlung der Lungentuberkulose. Erfahrungen und kritische Betrachtungen. Von Dr. A. Bruner, Oberarzt an der chirurgischen Universitäts-Klinik, München, und Dr. G. Baer, Oberarzt der Fürsorgestelle für Lungenkranke, München. Paper. Price, 3.60 marks. Pp. 65, with 13 illustrations. Berlin: Julius Springer, 1926.

Monograph on thoracoplasty for tuberculosis.

Animal Parasites and Human Disease. By Asa C. Chandler, M.S., Ph.D., in charge, Hookworm Research Laboratory, School of Tropical Medicine, Calcutta, India. Third edition. Cloth. Price, $4.50 net. Pp. 573, with 254 illustrations. New York: John Wiley & Sons, Inc., 1926.

Third edition of a well written and popular work.

Trial of William Palmer. Edited by George H. Knott, Barrister-at-Law. Second edition. Revised by Eric R. Watson, Barrister-at-Law. Cloth. Price, 10 shillings, 6 pence net. Pp. 348, with illustrations. Edinburgh: William Hodge & Co., Ltd., 1925.

A surgeon, turned murderer, uses strychnine as an agent.

Human Metabolism with Enemata of Alcohol, Dextrose, and Levulose. By Thorne M. Carpenter. Paper. Pp. 197, with 91 charts. Washington: Carnegie Institution of Washington, 1925.

Concludes that rectal feedings are absorbed and utilized without aid of secretions of upper digestive tract.

Das Sputum. Von Professor Dr. Heinrich von Hoesslin. Second edition. Paper. Price, 66 marks. Pp. 485, with 130 illustrations. Berlin: Julius Springer, 1926.

Complete consideration of bacteriology and laboratory study of sputum.

Methodik der Untersuchungen von Nervenelementen des makro- und makro-mikroskopischen Gebietes. Teil I. Von Prof. Dr. W. Worobiew. Paper. Pp. 130, with 39 illustrations. Berlin: Oscar Rothacker.

Research on staining of tissues of nervous system.

Pediatric Notes. By Wilburt C. Davison. Second edition. Cloth. Price, $1.25. Pp. 81. Baltimore, 1926.

Practice notes on Johns Hopkins methods of infant feeding and infant care.

Trial of George Henry Lamson. Edited by Hargrave L. Adam. Cloth. Price, 10 shillings, 6 pence net. Pp. 192, with illustrations. Edinburgh: William Hodge & Co., Ltd., 1913.

Another medical murderer who used aconitine.

The Medical Department of the United States Army in the World War. Volume VIII. Field Operations. Prepared under the direction of Maj. Gen. M. W. Ireland, the Surgeon General. By Col. Charles Lynch, M.C., Col. Joseph H. Ford, M.C., Lieut. Col. Frank W. Weed, M.C. Cloth. Pp. 1097, with illustrations. Washington: Government Printing Office, 1925.

Tabulae Biologicae. Herausgegeben von C. Oppenheimer und L. Pincussen. Band II. Thermochemie. Physikalische Chemie der Fermente. Elektrizität u. Elektrochemie. Strahlenlehre. Spezielle Biophysik. Sekrete. Paper. Price, $13. Pp. 567, with illustrations. Berlin: W. Junk, 1925.

Jaarboek der Rijksuniversiteit te Groningen, 1924-1925. Paper. Pp. 135. Groningen: J. B. Wolters, 1925.

Selected Contributions from the Peking Union Medical College. Volume V. Paper. Peking, 1925.

Miscellany

THE GORILLA AND MAN

In a series of lectures at the Royal College of Surgeons, in London, Sir Arthur Keith said that two extinct species of mankind, the Neanderthal and Rhodesian, had their faces modeled on gorilline lines. Early opponents of Darwin's theory laid stress on the fact that the foot of man was provided with a special muscle—the peroneus tertius. There was now no doubt that this muscle, which had not yet become firmly fixed in man's structure, occurred as a variation or sport on the foot of the gorilla, but had never been observed in that of any other ape or animal. In two highland, or Kivu, gorillas recently dissected by Dr. Morton of Harvard University, this muscle was fully formed; it occurred occasionally, as had been noted by European anatomists, in the feet of the Gabun, or lowland, gorilla. The muscles of the calf of man's leg had certain peculiarities in their arrangements; occasion*ally the calf muscles of the gorilla made an approach* toward the human disposition. Man's thumb had a special extensor muscle; it occurred as a sport in the thumb of the gorilla. On the inner side of man's upper arm was the fibrous remnant of a climbing muscle; on most gorillas this muscle was also in a degenerated state. Although the gorilla showed certain leanings toward man in its structure, yet, in this respect, it stood infinitely nearer to the chimpanzee than to man.

No one who had compared their bodies could doubt that the gorilla and the chimpanzee had risen from a common ancestor. Yet evolution had proceeded in their bodies and minds in opposite directions. In various breeds of chimpanzee there was a tendency for growth to stop short of the full point of maturity. The male chimpanzee, when its body reached about 10 stone (63.5 Kg.) in weight, stopped short, but that of the male gorilla went on until a solid weight of some 25 or 30 stone (from 160 to 190 Kg.) was reached. The highland, or Kivu, gorilla, which lived on the steep mountain sides of equatorial Africa, might weigh as much as 32 stone (203 Kg.). He was the giant of anthropoid apes. To explain why the chimpanzee had evolved in one direction and the gorilla in another, naturalists had to fall back on medical experience. When acromegaly was first observed, Dr. Harry Campbell was impressed by the resemblance presented by certain features to those of the gorilla. He sought to explain acromegaly in man as a reversion to an ancestral state. But it seemed more legitimate, in the present state of our knowledge of the action of hormones on the growth of the body, to regard gorilline characters, whether they occur as a normal manifestation in the life history of the gorilla, or as an abnormal manifestation in the life history of a person with acromegaly, as being due to an increased action of that element of the pituitary gland which influences the processes of growth.

The brain of man, said Keith, formed the climax of an ascending series from the marmoset through the gorilla. Between the highest gorilla and the lowest human brain we knew as yet only one intermediate stage—that of *Pithecanthropus*—and in size and pattern this brain has reached almost, if not quite, the threshold of humanity. The point of brain development reached by the human brain marked the furthest point attained by any primate, but in weight of body, volume of lung, size of tooth, massiveness of jaw and strength of muscles — particularly those of mastication — the gorilla crowned the primate series. Yet at birth the gorilla was smaller (under 5 pounds [2.3 Kg.] in weight) than the newborn child, and was just as nude and helpless. Its skull was as rounded and smooth as that of a human infant, and the muscles of mastication were no larger. The temporal muscles for example, started from the same base line on the side of the skulls of the gorilla, chimpanzee and man, but wherea the temporal muscles of the gorilla extended their origi *until great bony crests were formed along the vault of th* skull, those of the chimpanzee and of man stopped short o such an extreme. In man, the temporal muscles were arreste in their ascent at a stage corresponding to that reached b the gorilla in youth; in the chimpanzee, these muscles becam arrested at a point reached by the gorilla in early adolescence In man, the evolutionary tendency had been to retain mor and more the structural characters of youth; in the gorill the tendency had been in the opposite direction—to increas the size of jaw and strength of body. In his evolutionar career, man had moved in the direction of brain, while th gorilla had moved in the direction of brawn. The evolutionary process which had produced such diverse forms from common ancestor constituted at once the most enigmatic an also the most interesting experiment in the whole realm c nature.

THE TEACHING OF ROENTGENOLOGY

Organizers of special training courses for physicians in an given specialty always experience considerable difficulty i arranging the course of instruction so as to be adapted to th various talents and the widely differing degrees of preparation of the physicians who register for the course. That i peculiarly true of special training courses in a new science such as roentgenology. In the March number of *Radiology*, Dr. Guido Holzknecht, professor of medical roentgenology, tells how he endeavors to solve the problem in the teaching of roentgenology at the Central Roentgen Institute, Vienna, Austria.

The most important feature in the described scheme of instruction is the hour that the director of the institute spends in the initial examination of each applicant for the course as to his individual capacities and previous training. The examinations reveal at once that every applicant needs a different course of study. Holzknecht shows how the roentgenologic institutes of large hospitals can solve what at first seems impossible of solution, provided they do not lose sight of the original purpose of the institute, the best possible care of patients in need of roentgenologic treatment.

The division of the work of instruction among the technicians and the several assistants is the principle on which the individual instruction is based. The distinction between plate diagnosis and fluoroscopic diagnosis and therapy furnishes the basis for the first subdivision of the instruction, since it separates from the diagnostic point of view those with a surgical bent from those who are interested more particularly in internal medicine. The directors of those two departments, together with their assistants, perform their work in the presence of the pupils, while thinking aloud. "The pupils listen, offer aid, and eventually are allowed to participate independently, for direct practice is recognized as the fundamental principle applicable to their training." As opportunity offers, general courses for beginners and special courses for advanced pupils are held. The courses are not combined, even for short periods, as this has been found to be impracticable. Once a week informal conferences are held, which are attended particularly by the more advanced pupils. The books recommended for study vary with each pupil. To sum up, the four essential forms of instruction employed in the special training in roentgenology given physicians consist of: study of textbooks adapted to the individual's requirements; practical laboratory work, lecture courses and seminar. But no absolutely fixed schedule is followed. The method Professor Holzknecht describes seems well adapted not only to the teaching of roentgenology but also, with modifications, to instruction in other medical specialties when the applicants, as is usually the case, vary greatly in ability, capacity and previous medical training.

Medicolegal

When and on Whom Demand for Necropsy Should Be Made

(Gath v. Travelers' Ins. Co. of Hartford, Conn. (Ohio), 149 N. E. R. 389)

The Supreme Court of Ohio, in reversing a judgment that was rendered in favor of the defendant in an action on a policy of accident insurance, says that a clause in the policy gave the company the right and opportunity to make a necropsy in case of death. It appeared that the agents of the company had knowledge, at least thirty hours before the burial, of the death of the insured, and entertained a belief that his death was caused by other than accidental means. The widow was the sole beneficiary under the policy, and continued to reside at the family home during the time between the death and the burial. A son who lived in Michigan was at the time at his mother's home, looking after the funeral arrangements. At no time between the death and the burial did the widow have any notice of a demand for a necropsy on the body of her husband. The notice which she received of that demand was received three days after the burial. A verbal demand had been made twice on the son, who each time unequivocally said that he would not notify his mother of the demand, but would assume all responsibility therefor. The court holds that the demand for a necropsy was not seasonably made by the agent of the insurance company, and was not made on the proper person. When the death is known to an agent of the insurer, a reasonable time before burial, who has justifiable grounds for entertaining the belief that such death was caused by other than accidental means, the demand for a necropsy, to be seasonable, must be made before burial. Where a widow living at the home is named as the sole beneficiary of the insured, under the opportunity clause of the policy such demand should be made on her. Verbal requests for opportunity to make a necropsy, made by an agent on the son before the burial, are not sufficient, where the son unequivocally notifies the agent that he will not, and in fact does not, communicate such requests to the widow beneficiary. Necropsy clauses, such as that in this case, are construed strictly by the courts in favor of the insured, and require a demand for a necropsy to be made before burial, especially when the death of the insured is known to the agents of the company, and it has reasonable grounds to believe that it was not caused by accidental means. Whether a court should authorize the disinterment of a body for purposes of a necropsy naturally depends on the peculiar circumstances arising in each case. The reported cases on the subject show that the courts very reluctantly permit any interference with human remains when once interred.

Death from Pneumonia After Septicemia from Lancing

(Cameron v. Massachusetts Protective Assn. (Mo.), 275 S. W. R. 988)

The Kansas City (Mo.) Court of Appeals, in affirming a judgment in favor of the plaintiff, who was the beneficiary under an accident insurance policy, says it thinks that there is no question but that if the insured, in lancing or cutting a pimple on his left forearm, unintentionally used an instrument having thereon an anaerobic germ, or germs, and that such germs were inserted into his system, the occurrence was an accident within the meaning of the policy. He intended to cut himself, but the insertion of the germs into his system was unintentional. There was testimony from which the jury might find that the pimple had been punctured by some instrument having on it germs which resulted in blood poisoning. The evidence showed that before the cutting of the pimple the insured was a man 40 years of age, strong physically, and in good health. There was nothing in the evidence to suggest that he would intentionally do such an unnatural thing as to insert deadly germs into his system; on the other hand, the presumption was to the contrary. There was testimony tending to show that the germs he inserted into his system caused the pneumonia from which he died, and there is no question but that the plaintiff was entitled to recover on the policy, which stated that it insured "against loss resulting from bodily injuries effected directly and independently of all other causes by accidental means (excluding self-destruction, or any attempt thereat, while sane or insane), and due solely to external, violent and involuntary causes, and leaving visible marks upon the body." The court does not agree with the contention that the provision of the policy "that this policy does not cover death due to disease, whether acquired accidentally or otherwise," prevented recovery in this case for the reason that the insured died of a disease. Various definitions of disease were given by the physicians who testified in this case, and that even a broken leg would be a disease. However, the defendant stated in its brief, "Of course, it was not intended in the present policy that a broken leg should be regarded as a disease"; and, with this admission, it seems to the court that the point falls. The construction to be given to this provision of the policy was that it meant that the insurer was not to be liable for death due to disease acquired accidentally save through "bodily injuries, effected directly and independently of all other causes by accidental means (excluding self-destruction, or any attempt thereat, while sane or insane), and due solely to external, violent and involuntary causes, and leaving visible marks upon the body." If this was the meaning, the facts in this case did not come within the exceptions.

Quarantine by Health Officer for Venereal Disease

(Ex parte Fisher (Calif.), 239 Pac. R. 1100)

The District Court of Appeal of California, First District, division 1, says that in this application for a writ of habeas corpus to secure the petitioner's release from quarantine, it appeared from the petition that the health officer of the city and county of San Francisco, after an examination, had ordered the petitioner quarantined at the county hospital, he having found her to be suffering with a gonococcus affliction. It was contended that such detention was unlawful, for the reason that such officer was without authority to control the body of the petitioner, such power residing alone in the state board of health. But section 2979a of the political code of California confers on health officers of every county or city and county the right to take such measures as may be necessary to prevent the spread of diseases of the character of which the petitioner was suffering. While the section does not in express terms confer on the officer in question the right to take possession or control of the body of one so afflicted, as it does in the case of the state board of health, the isolation of one afflicted with an infectious disease is a reasonable and proper measure to prevent its increase and spread. The petition showing on its face a legal cause of detention, the application for a writ of habeas corpus was denied.

Death from Puncturing Bowel in Medicating Hemorrhoids

(Hoosier Casualty Co. v. Royster (Ind.), 149 N. E. R. 164)

The Supreme Court of Indiana, in affirming a judgment in favor of the plaintiff, says that she, as beneficiary, brought this action on an accident insurance policy issued by the defendant company to her husband. The policy insured against injury resulting "necessarily, directly, and independently of all other causes from bodily injuries, effected through external, violent, and accidental means." The complaint alleged that the death of the insured was due to external, violent and accidental means in that he was afflicted with hemorrhoids and in treating them he used a tube for the introduction of medicine into the lower bowels, in doing which he accidentally and without intention on his part punctured the lower bowels with the tube, from which injury he sickened and on the fourth day after the accident died; that as visible marks of the injury there were the hole about one-fourth inch in diameter so punctured in the lower bowel and, in a short time after the injury, a swelling and hardening of the lower part of the abdomen. The evidence showed that the hemorrhoids extended about 2 inches up in the bowel, and that an operation performed before the death of the insured showed that the injury in the lower bowel was about 10 inches above the opening; that the wall of the bowel about the injured place was in a healthy condition, and that there was no indication of any disease condition of the bowel at or near the puncture. A surgeon testified that in his opinion a person would not be able to withstand the pain long enough to puncture the bowel by steady pressure, manipulating the instrument himself, but that if, in inserting a tube, he got it against a fold of the bowel or some other obstruction, and the end of the tube should then slip and suddenly move more rapidly against the wall of the intestine, and strike it with force, that would cause such a puncture as was found; or, if a person had taken a sitting posture, and suddenly and accidentally put more weight on the tube than was intended, causing it to enter suddenly and with force, it could cause the wound that was found. The court thinks that a fair consideration of the evidence would indicate that, when the assured used this instrument which he had used before to medicate his hemorrhoids, something accidental and unexpected did occur; that was that the instrument was, on account of some unexpected occurrence, while he was using it, unintentionally inserted beyond the place where the medicine was intended to be used, and the injury thus produced. Wherefore the court holds that the death of the insured occurred through external, violent and accidental means, within the meaning of the policy on which this action was brought; and that the finding of the trial court in favor of the plaintiff was sustained by sufficient evidence, and was not contrary to law.

Insane and Other Delusions of Testators

(Burris et al. v. Burris et al. (Ky.), 276 S. W. R. 820)

The Court of Appeals of Kentucky, in affirming a judgment allowing the probate of a will, says that none of the facts relied on to constitute an insane delusion measured up to the legal requirements necessary for its creation. It is the law that if a testator at the time he executes his will is laboring under some insane delusion with reference to a matter relevant to his free agency to act in disposing of his property by will, his testamentary disposition will be set aside therefor as not having been his free and untrammeled act. The pertinent question then is, whether there is evidence of such insane delusion as to produce that effect. If there is, it then becomes the duty of the court to submit it to the jury by a proper instruction. In determining the first proposition, it is well to remember that it is not every delusion under which a testator may be laboring that rises to the dignity of an insane delusion so as to invalidate his will; for an opinion, conclusion, or impression as to the existence of certain facts entertained by him, though founded on false premises or untrue surmises, is a delusion but not necessarily an insane one. One may be deluded into such erroneous beliefs by vague and insufficient evidence, without possessing any of the symptoms of insanity, and when his delusion produces no disease of his mind or in anywise dethrones his reason. In such case the possessor of the delusion labors only under a misconception of the facts without any impairment of his mentality.

An insane delusion, such as to render a will invalid, is defined by the authors writing on the subject:

> As a belief in things which do not exist, and which no rational mind would believe to exist. The essence of an insane delusion is that it has no basis in reason and cannot be dispelled by reason. The subject-matter must have no foundation in fact, for there is no such thing as a delusion founded on facts. It must not be founded on evidence, for if there is any evidence, however slight or inconclusive, which might have a tendency to create the belief, such belief is not a delusion. Nor can one be said to act under an insane delusion if this condition of mind results from an inference or a process of reasoning, however illogical, drawn from facts which are shown to exist. A delusion is therefore to be distinguished from a mere mistaken opinion. An insane delusion is not established when the court is able to understand how a person situated as the testator was might have believed all that the evidence shows that he did believe and still have been in full possession of his senses. A false belief, even in facts which actually did not exist, or a belief which a rational person may entertain, does not constitute an insane delusion. Nor are absurd opinions, however unfounded, insane delusions.—22 R. C. L. 102, 103, par. 54.

That definition is approved by all the courts of the country, including this one, under the varying facts of each particular case.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Occiput Posterior. P. W. Toombs, Memphis, Tenn.—p. 206.
Relation of Physiology and Mechanics to Management of Labor. W. A. Fowler, Oklahoma City.—p. 212.
*Preparation of External Genitalia for Delivery with Iodine-Alcohol. B. Lankford, Norfolk, Va.—p. 219.
*Treatment of Edema of Toxemia of Pregnancy with Ammonium Chloride. R. D. Mussey, Rochester, Minn.—p. 222.
*Intramuscular Injection of Magnesium Sulphate for Control of Convulsions in Eclampsia. L. Dorsett, St. Louis.—p. 227.
Prevention of Stillbirths. C. R. Hannah, Dallas, Texas.—p. 231.
Case of Mesenteric Cyst. E. D. Clark, Indianapolis.—p. 238.

Nature of Chronic Appendicitis.—Hertzler's opinions are based on an examination of more than 3,000 appendixes. He says: "Fibrotic changes in the appendix, no matter of what degree, are not attended by clinical symptoms. The anatomic structure of appendixes commonly removed under the diagnosis of chronic appendicitis shows no variation from the appendixes of individuals suffering from no abdominal complaint whatsoever. The minimal changes alleged to be present in cases of so-called chronic appendicitis are wholly inadequate to explain the symptoms ascribed to them considered in the light of like changes in other organs of the body. Mere alleged relief after the removal of the appendix of symptoms is not sufficient to prove that the appendix was the cause of the symptoms. The vast majority of patients so operated on do not even claim relief of their symptoms. The symptoms alleged to be due to chronic appendicitis can be relieved by searching out the actual cause and by removing it, relieving the patient without molesting the appendix."

Prolapse of Placenta.—Rucker relates the case of a septipara, aged 28, pregnant, who suddenly felt faint and began to bleed. She walked home, a distance of one-half mile, without difficulty. After getting home she began to have pains and the bleeding commenced again and continued until the placenta was expelled at 3 a. m. It was devoid of membranes, except at one edge where there was a little tag about 3 by 7 cm. The attachment of the cord was eccentric. The fetal surface of the placenta was smooth and glistening, and there were no torn blood vessels. The maternal surface was apparently intact. It was somewhat lobulated. There was an oval area about one fourth the total area of the placenta extending to the periphery that was distinctly darker and firmer than the rest of the organ. A dead baby was born fifty minutes later. It weighed 3,175 Gm. Ossification was complete. Nothing unusual was found at necropsy.

Treatment of Placenta Praevia.—Kellogg asserts that all central and partial praevias are best treated by low abdominal cesarean section, whether the baby is viable or nonviable, living or dead. Marginal praevia is best treated by Voorhees' bag induction. Moribund or very sick patients with placenta praevia should be rested, and bleeding controlled by necessary methods, including tight cervical and vaginal pack and pressure over and above the fundus; transfusion and operation should be done on pulse and pulse pressure reaction, and then retransfusion done. It should always be the effort to ascertain as nearly as possible how much blood has been lost and to replace that amount as nearly as possible. Hysterectomy following section should be practiced frequently, each case to be considered by itself on the following grounds: risk of sepsis from previous history, persistent bleeding following the section, and number of dependent children at home. If a woman has several, as is usually the case, hysterectomy seems to improve her chances, and should unhesitatingly be done.

Preparation of External Genitalia for Delivery.—Lankford regards the 3.5 per cent iodine-alcohol or the 4 per cent mercurochrome method of preparation of the genitalia for delivery a procedure that is safer than any yet advanced; each is simple and can be used by any one who will take the trouble to have the solutions prepared shortly before expected delivery. The iodine-alcohol method would seem to be the simpler of the two, as it can be used with effect as late as five minutes before delivery, whereas the use of mercurochrome is advised at least one hour before any operative procedure.

Ammonium Chloride in Toxemia of Pregnancy.—In these cases of edema of toxemia of pregnancy, Mussey gives ammonium chloride in 1.5 Gm. doses in gelatin coated capsules. Up to 10 Gm. is given daily, even after diuresis has been effected, and if possible until the edema disappears. Usually a total of from 50 to 100 Gm. of ammonium chloride was given. The patient is also kept in bed on a 1,500 calory diet containing 50 Gm. protein, with a minimum of salt, and 800 cc. of fluid. Following the disappearance of the edema, the fluid intake was increased.

Control of Convulsions.—The intramuscular injection of magnesium sulphate, in 15 cc. doses, Dorsett says, will control the convulsions of eclampsia and decreases the intracranial pressure by relieving the cerebral edema, stimulates diuresis, and aids in the diminution of the general edema. He uses a triple crystallized sterile, nonanhydrous solution, put up in 15 cc. ampules. The frequency of administration is regulated entirely by the frequency and severity of the convulsions and the general condition of the patient. There has as yet been no respiratory disturbance of any kind. Several of the patients have received as high as 100 cc. of the drug within twenty hours without any perceptible reaction.

Tetanus and Gas Gangrene.—The prophylaxis of tetanus and gas gangrene is discussed by Meyer, 148 cases occurring in California between June, 1922, and March, 1925, forming the basis of his study. Nineteen of these were cases of tetanus neonatorum, suggesting that a primitive type of delivery is still practiced in certain strata of the population. Vaccination was followed by two cases of tetanus; eight were postoperative cases of tetanus. As very few instances of catgut infection have been proved, Meyer says it is more reasonable to suspect the intestinal canal of the patient himself as the source of the postoperative tetanus. Since it is now definitely established that tetanus spores or any other gas gangrene producing anaerobe ingested on raw vegetables may multiply in the intestinal tract and remain there in large numbers, the surgeon should fully appreciate this insidious source of wound infection before he suspects his surgical instruments, sutures and dressings. It is not unlikely that many of the postoperative anaerobic infections are from within, e. g., the intestinal canal of the patient and not from without. These data, as a whole, emphasize anew the well known fact that relatively trivial injuries may lead to tetanus. The most deplorable condition which was recognized from the analysis of the data is the fact that only three, possibly four, people who received puncture wounds, lacerations, contusions, or compound fractures of the type considered most liable to tetanus infection had the benefit of a prophylactic injection of antitoxin. The majority of the patients involved in this series never consulted a physician, and either ignored the injuries or treated them by unknown remedies. On the other hand, at least five physicians failed to give antitoxin, although the character of the injury (compound fracture, deep nail puncture) should have aroused suspicion of the possible consequences. Furthermore, the prophylactic treatment was not conducted in accordance with established practice, and, Meyer says, one is forced to conclude that those responsible were not familiar with the basic principles of the prevention of tetanus.

Blood Changes Effected by Parathyroid Extract.—Sherill and Copp report the changes in blood serum calcium, coagulation time and red cell volume in various types of clinical conditions, such as arthritis, paralysis agitans, hemophilia, mental deficiency with convulsions, epilepsy, gastric ulcer, neurosis and purpura hemorrhagica resulting from the administration of parathyroid extract. The serum calcium was increased in amount, and the coagulation time reduced.

Gassy Indigestion.—The common complaints of "gassy indigestion" and "spells with the heart" in middle aged and elderly women, according to Campbell, are generally due to chronic inflammation of the gallbladder and appendix. Gallstones are not always present and are not essential to the development of the complex. Removing the gallbladder does not in these cases interfere with the function of the biliary system. The best treatment is to remove the gallbladder and appendix at the same time. The mortality of this procedure is low, and the results wonderfully satisfactory in that the patient can afterward eat ordinary food and be comfortable.

Lowering Basal Metabolic Rate by Iodine.—Fitzgerald compares the effectiveness of compound solution of potassium iodide in lowering the preoperative basal metabolic rate in cases of exophthalmic goiter with that of resublimed iodine given in solution in dilute hydriodic acid. Lowering of the basal metabolic rate was effected in nearly all cases, irrespective of the kind of iodine used. The two methods of treatment produced practically the same diminution in the basal metabolic rate and in about the same length of time. It was found necessary to give four times as much resublimed iodine as compound solution of potassium iodide to produce the same clinical results.

Pulmonary Tuberculosis and Pregnancy.—Among the first 14,000 histories of the indoor obstetric service of Johns Hopkins Hospital reviewed by Bridgman and Norwood, 134 patients were grouped as having pulmonary tuberculosis in one or more of its various forms. In fifty cases the diagnosis of tuberculosis was questionable. In seventeen cases the history and signs pointed conclusively to the diagnosis of pulmonary tuberculosis in an inactive stage at the time of delivery. There were seventeen cases of clinically definite pulmonary tuberculosis, inactive at the time of delivery and thirty-one patients who had active tuberculosis during pregnancy and at the time of delivery. There were twelve cases of active tuberculosis in which a therapeutic abortion was done, and seven cases of inactive tuberculosis with therapeutic abortion. In nineteen cases pregnancy was associated with tuberculosis and some other disease, syphilis in ten instances. As to what shall be done in the case of a pregnant woman in whom tuberculosis is found, Bridgman and Norwood are emphatic in stating their position of treating the tuberculosis to the uttermost, disregarding the pregnancy, and prescribing rest and more rest, preferably in a sanatorium, and under those whose life's business is the treatment of tuberculosis. Artificial termination of pregnancy is not indicated, and in this series has led to a somewhat worse outcome. On the other hand, a later sterilization is an entirely different matter

—to be done at some period after the patient has been through her pregnancy, and the tuberculosis has become quiescent. It is obviously not right to allow a tuberculous mother to be subjected to repeated pregnancies with repeated recrudescences of an old lesion. The use of tubal sterilization seems, in general, to be the most satisfactory procedure, but even such operative measures should be adopted only after a consultation between obstetrician and practitioner, and then only if they agree that in the individual patient future pregnancies are contraindicated.

Experimental Premature Separation of Placenta.—An experimental premature separation of the placenta was effected by Hofbauer and Geiling by injecting histamine intravenously or intracardially, into pregnant guinea-pigs and cats. A noteworthy phenomenon was observed in the uterine mucosa, namely, a conspicuous hemorrhage extending along the course of the blood vessels, while the uterine glands adjacent to the placenta were filled with fresh blood, which in places lifted up the epithelial covering of the uterine mucosa. Within the uterine wall the occurrence of a marked edema, spreading apart the muscle bundles, was a striking feature. In the guinea-pig, as well as in the cat, the occurrence of thrombi in the veins of the decidua and of other organs, especially the liver, could be demonstrated. In some experiments the abdominal cavity contained a variable amount of free fluid, which was highly conspicuous in a few instances. The changes encountered in the livers of the cats aroused special interest, peripheral necrosis and stagnation of the bile being the most prominent features. The results obtained are in harmony with the recent tendency pointing to the association of the placenta with a toxemic process, and indicate that a sudden access of histamine to the circulation of the pregnant woman might well account for the sudden appearance of the accident in question with its traits of alarming symptoms.

Effect of Temperature on Clostridium Botulinum.—As to the effect of temperature on *Clostridium botulinum*, Starin says that death of the organism does not occur at any temperature used, even after three months' incubation. Even in those mediums in which no evidence of growth or toxin production could be detected, transplants to a suitable medium, such as beef heart, resulted in abundant growth of the organism with normal toxin production. Disintegration of the medium parallels the production of toxin, although in some instances lethal doses of toxin may be present with practically no noticeable changes in the gross appearance or in the odor The four vegetables used ranked as follows in the rate of toxin production, and in the quantity of toxin produced corn, peas, string beans, spinach. The high initial acidity of the beans and spinach may be the responsible factor for the slight growth and toxin production in these mediums

Pneumonia Caused by Bacillus Mucosus.—Eighteen cases of infection of the lung by *B. mucosus* were studied by Belk, and a provisional report is made of a chronic pulmonary lesion caused by this organism Six cases of lobar pneumonia due to *B mucosus* are reported in detail, with references to thirty-eight cases recorded in the literature.

Germicidal Properties of Soap.—Walker summarizes his study as follows the meningococcus is killed in two and a half minutes by N/80 to N/640 solutions (0 4 per cent to 0 04 per cent) of the soaps of the fatty acids ordinarily present in soap bases; 1 per cent phenol is required to kill under the same condition The gonococcus is killed in two minutes by N/640 to N/5120 solutions (0.04 per cent to 0 006 per cent) of the same soaps, 0 5 per cent phenol killed under the same condition Sodium resinate also possesses marked germicidal activity toward these two organisms. The meningococcus, on being tested with four commercial soaps, showed approximately the same degree of susceptibility as would have been anticipated from the action of the chemically pure soaps The susceptibility of meningococci and gonococci is such that they (along with streptococci, pneumococci and diphtheria bacilli) will be killed readily by any ordinary soap used with a reasonable degree of care The dysentery bacilli and paratyphoid bacilli react to the different soaps in the same manner as previously shown for typhoid and colon bacilli that is, they are killed by moderate concentrations of the soaps of the saturated acids, but are completely resistant to the soaps of the unsaturated acids at ordinary temperatures. The most readily available soap to be used against the typhoid bacilli, paratyphoid bacilli and dysentery bacilli is salt water soap prepared exclusively from coconut oil.

Influence of Anaerobes on Botulinum Toxin.—Dack found that the filtered toxin of *Clostridium botulinum* added to beef heart medium is gradually destroyed by the growth of *Clostridium sporogenes* in it. The power to destroy botulinum toxin is also possessed by several other anaerobic species with proteolytic and nonproteolytic properties. The destruction of the toxin is not due to a change in hydrogen ion concentration

Behavior of Botulinum Toxin in Alimentary Tract.—Botulinum toxin when mixed with stomach tissue and abdominal wall tissue from guinea-pigs and mice in vitro and incubated at 35 C for one hour, Dack says, was not reduced in potency, except in two cases in which mouse stomachs were used The reduction, however, was slight in these cases. Botulinum toxin was not completely destroyed in the stomachs and small intestines of rats and guinea-pigs receiving injections of the toxin directly into the stomach. Its presence was definitely demonstrated after twelve hours in guinea-pigs and after three hours in rats. In two cases out of seven toxin was demonstrated in the blood of guinea-pigs fed with botulinum toxin No toxin was found in the blood of rats fed with large doses of botulinum toxin. Toxin was found in the blood of rats and guinea-pigs three hours after intravenous and mesenteric injections of the toxin.

Concentration of Blood Corpuscles in Diabetes.—The relative concentration of corpuscles in capillary and venous blood of twenty-seven diabetic patients in the morning and evening is compared by Root and White. Variations in arterial tension between these periods do not correlate constantly with any change in the corpuscle concentration. In certain patients, with high diastolic blood pressure, the capillary red cell count was higher than the venous red cell count at night but lower in the morning. This reversed relation suggests capillary stasis at the end of the day and was more marked in patients with obvious vascular disease. Increases in venous pressure produce the contrary effect; namely, high venous count and low capillary count.

Internal Secretion of Parathyroids.—Aqueous acidic solutions of a calcium mobilizing substance of the parathyroids of oxen were used by Berman to determine their effects on parathyroidectomized dogs, cats and white rats. The results show that protein-lipin-free solutions made by extraction of parathyroid glands with alcoholic solutions of acid (which were first used) or with aqueous solutions of acid (which were used immediately after the extractive efficacy of alcoholic solutions of acid had been established) will prevent or relieve the known cardinal effects following removal of the parathyroids, namely, the retention of phosphate, the decrease of blood calcium, the increase in electrical irritability of the nerves, the muscular hyperirritability and the various other symptoms. These results established the presence in the extracts of an internal secretion of the parathyroids since all the other criteria of substitution therapy are satisfied.

Standardized Wassermann Report.—Casselman aims to induce laboratory workers to state the results of their Wassermann tests in simpler language which will be better appreciated by clinicians.

Comparison of Kolmer-Wassermann and Kahn Tests.—Examining 1,600 serums with both these tests, Owen and Cope obtained a practical check in 93.8 per cent of the cases. The divergence between the two tests lies almost wholly among the treated patients.

Comparison of Kolmer and Kahn Tests.—Giordano asserts that the two tests run parallel in about 96 per cent of the serums. Both tests occasionally render a false negative which is usually picked up by one or the other when the two tests are run parallel.

Comparison of Kahn and Kolmer Tests.—In tests done by Kelly in 110 cases, a concordance of results was found in 105, or 95.45 per cent. There is no convincing evidence that a positive reaction occurred with the Kahn or Kolmer test, which was inconsistent with clinical or other serologic findings.

Pharmacology of Benzyl Alcohol and Its Esters.—Observations made by Gruber on animals showed that sodium benzyl succinate caused a rise in blood pressure in 67 per cent of the injections and sodium dibenzyl phosphate in 35 per cent of the cases; that the heart is slowed in many cases, in others markedly accelerated, and that sodium dibenzyl phosphate causes a precipitate in the presence of calcium salts. Hence, it would seem inadvisable to use these drugs in arterial hypertension. Intravenous administration of the latter drug, Gruber says, would certainly not be wise.

Intestinal Obstruction and Pernicious Anemia.—A case of clinically typical pernicious anemia occurring with a malignant obstruction of the duodenum and colon is reported by Haden. The findings in this case are said to be further evidence of the intestinal origin of pernicious anemia.

Analysis of Cardiovalvular Cases.—Sixteen, or 3.9 per cent, of the 401 cases analyzed by Perla were attributable to syphilitic infection; 199, or 49.8 per cent, to rheumatic infections, and in 186 cases, or 46.3 per cent, the exact etiologic factors could not be determined. The nature of the lesion was: pure aortic insufficiency, 3.7 per cent; combined mitral and aortic disease, 24.4 per cent; mitral disease, 71.9 per cent; patients with aortic insufficiency alone or combined with other lesions, 113. Auricular fibrillation occurred in 112 cases. Of these, 78 per cent were in the rheumatic group, 20 per cent in the undetermined group and 1.5 per cent in the syphilitic group. Fifty-seven per cent of all cases of auricular fibrillation occurred in mitral stenosis. A palpable spleen was found in 12 per cent of all cases. The duration of life from the time of onset is longest if the disease is acquired under 20. A defect of the valves is not disease of the heart.

Liver Cirrhosis in Children.—Four cases are recorded by Poynton and Wyllie. One was that of a girl, aged 9, with intermittent jaundice, epistaxis and hematemesis, most likely a case of portal cirrhosis, associated with tuberculosis, possibly mesenteric, and without congenital predisposition. Two other patients, brother and sister, had enlargement of the abdomen from birth and very little jaundice, probably a form of hypertrophic cirrhosis, similar to the sclérose sans ictère described by Hayem. The authors think that this cirrhosis is of portal rather than of biliary origin. These two cases are specially interesting owing to the rarity of a familial occurrence of the portal type as compared with the biliary form of hepatic cirrhosis. In the fourth case, the size and hardness of the liver, and the duration of the jaundice (eight weeks) were unusual. Also, outbreak of fever, with the rapid and great enlargement of the spleen, as a late event, are unusual features in the catarrhal jaundice of childhood. The remarkable subsidence of the liver and spleen before the child left the hospital favored some degree of biliary obstruction rather than cirrhotic changes in the liver.

Epinephrine in Rheumatic Heart Block.—Two points are stressed by Sutherland: the value of epinephrine in conditions of heart block when the symptoms are so severe that death seems imminent, and the early appearance of a definite and grave cardiac lesion as the result of rheumatic infection, and before any other evidence could be detected as to what the nature of the illness was.

Incidence of Rickets in London Hospital.—One hundred and sixty-nine children were examined radiographically and clinically for evidence of rickets at the Queen's Hospital for Children in April, 1925. Two rachitic children were excluded, since they were sent to the hospital for that disease. Of the 167 remaining, thirteen had radiographic evidence of rickets (i. e., 8 per cent), but if only infants between the ages of 4 and 13 months are considered, seventy-two are left, eleven of whom had rickets, an incidence of 15 per cent.

Incidence of Rickets in London.—In a series of 339 cases occurring between birth and 2 years, there were four cases of active roentgen-ray rickets, 1.2 per cent of the total. One hundred and ten cases showed clinical rickets which was proved to be healed, showing that 32 per cent of the children had had rickets. Ninety-two per cent of the children were having some cod liver oil preparation. Evidence is produced which suggests that cod liver oil protected some children from rickets, and healed rickets in others. The diet of the normal children showed that 0.3 per cent were fed on dried milk, 0.4 per cent on cow's milk, 0.1 per cent on sweetened condensed milk and 0.2 per cent on breast milk. Ninety-six per cent of these, however, were having cod liver oil, and the 4 per cent remaining were breast fed.

Results of Splenectomy in Purpura Hemorrhagica.—Of fifty-eight cases of purpura hemorrhagica reported by Williamson in which splenectomy was done, fifty patients are well, two are improved and six are dead. Williamson says that operation should be reserved for chronic cases which fall into two groups: (1) those in which chronicity with severity so interferes with the normal life of the subject that a state of chronic invalidism is established; (2) those in which the severity of the hemorrhages and the frequency of its occurrence constitute a real danger to the life of the patient.

Ketonuria and Urinary Acidity.—The average urinary p_H in forty-two cases exhibiting ketosis was 5.86, while that of the controls was 6.37. In none of the cases of ketosis following tonsillectomy was a urinary acidity encountered which approached a point indicative of acidosis. The p_H lay within normal limits in every case. A simple method of testing the urinary acidity is described. To 1 inch of urine in a test tube is added 5 drops of bromcresol purple (0.04 per cent aqueous solution). If the color obtained is purplish, no further tests need be carried out. The p_H is on the alkaline side of 6.4. If a yellow color is obtained, to a like quantity of urine in another tube is added 5 drops of methyl red (0.02 per cent in 60 per cent alcoholic solution). If the color then obtained is yellowish orange and not a deep pink, the urinary acidity lies to the alkaline side of p_H 5.4, and no danger from an acidosis need be feared.

Immunotransfusion for Septicemia.—Four cases of proved septicemia treated by immunotransfusion with one recovery and three deaths are described by Lloyd and Schlesinger. Success resulted in a pneumococcal septicemia consequent on empyema, and seems attributable to the transfusion.

Effect on Vitamins of Chemical Preservation of Eggs.—Chinese preserved eggs, or "pidan," offer an unusual opportunity for the study of some of the conditions under which the stability of vitamins may be affected. The preserved eggs are more or less chemically changed products of fresh ducks' eggs which are presumably rich in vitamin A, vitamin B, and the antirachitic food factor which exhibits certain vitamin-like properties. "Pidan" is made from raw ducks' eggs by applying a mixture of slaked lime, straw ash, soda, table salt and water. A study made by Tso of the stability of the vitamins in these preserved eggs has shown that the originally rich vitamin B content is practically completely destroyed, but that the potency of vitamin A and the antirachitic food factor is little or not at all affected.

Vitamin B of Lemon Rind.—From the experimental results obtained by Willimott, it is evident that vitamin B is present in appreciable amounts in the rind of the fresh lemon. This supply of B, though sufficient for reproduction, was inadequate for successful rearing.

Nitrogen and Sulphur Metabolism.—Further evidence is adduced by Wilson in favor of the view that in the storage of protein the sulphur is retained first.

Chemical Nature of Subcutaneous Fat of Infants.—The analytic constants of the subcutaneous fat of eight infants and one adult have been determined by Channon and Harrison. The iodine value is lowest at birth and increases to the adult value from the eighth to the twelfth month of life; there is a corresponding decrease of melting point with age. The saponification value is almost constant at 200. Similar analyses have been made in four cases of sclerema neonatorum in which the fat appears to have a higher melting point and a slightly lower iodine value than the corresponding values of the fat in infants of the same age. The raised melting point is believed to be due to the presence of an excess of glycerides of the higher fatty acids—probably of palmitic acid—which causes a slight decrease in the oleic acid content of the fat. Subcutaneous tissue in cases of sclerema contains an abnormal amount of cholesterol, calcium and phosphorus.

Determination of Iron in Blood, Tissues and Urine.—Methods are described by Fowweather for determining the amount of iron present in the blood, tissues and urine, using the colorimetric method dependent on the formation of ferric thiocyanate in the presence of acetone. It is shown that these methods are capable of a high degree of accuracy. They are simpler and less time-consuming than the methods at present in use.

Excretion of Phosphate During Water Diuresis.—Havard and Reay assert that the rate of phosphate excretion is independent of the water rate even when, owing to copious diuresis, the urinary phosphate is below the level of the plasma phosphate. It is shown that this is inconsistent with the view that phosphate is a "no-threshold" substance as represented in Cushny's theory of kidney secretion. The bearing of this result on other theories of kidney secretion is briefly discussed.

Fat Soluble Vitamin Diet.—A description is given by Smith and Chick of the diet and general management found satisfactory in breeding rats for nutritional work on fat-soluble vitamins. The diet used, consisting of cereals, fresh vegetables and milk, is moderately rich in vitamin A but poorer in vitamin D, except in summer, when fresh pasture milk contains a much increased amount of this vitamin The experiment of replacing fresh milk in the diet of the pregnant and lactating mothers by dried milk prepared from the winter milk supply has proved successful in lessening the degree of irregularity among the young

Antirachitic Value of Fresh Spinach.—According to Chick and Roscoe, fresh leaves of spinach are a rich source of vitamin A, a small daily ration (0 1 Gm and upward) encouraging growth and lessening or preventing xerophthalmia in young rats on diets devoid of fat-soluble vitamins Spinach grown in the open in winter, spring or autumn possesses no antirachitic properties that can be demonstrated by the methods employed. Spinach leaves when irradiated with ultraviolet rays from a mercury vapor quartz lamp become powerfully antirachitic

Antirachitic Value of Winter Spinach.—The fresh leaves of winter-grown spinach added to an experimental diet caused an even greater improvement in the well-being of rats and in the rate of growth than was caused by the addition of cod liver oil The weight of the skeleton was not, however, proportionally increased. The conclusion is drawn by Boas that winter spinach contains an amount of vitamin D which is negligible compared with its content of vitamin A.

Systemic Factors in Genesis of Cancer.—The results presented by Cramer indicate that there are systemic factors influencing the genesis of cancer, and experimentally, at least, the resistance against the genesis of cancer can be diminished Incidentally, it was found that *autotransplantation of minced spleen tissue into a splenectomized mouse leads to regeneration of the spleen.*

Estimation of Fat in Feces.—Fowweather asserts that any method of analysis of dried specimens of feces will show a fat composition which varies to a greater or less degree from that of the specimen as passed Not only are the dry methods inaccurate in a purely scientific sense, but the inaccuracies are such as to lead to erroneous deductions with regard to the clinical significance of the figures obtained The wet method affords a more efficient means of extraction

Fat in Feces.—The feces in eighty surgical cases were analyzed by Fowweather by the wet method The average amount of total fat was decidedly less than given by Cammidge's figures There was a preponderance of free over combined fatty acids. In 80 per cent of the cases the percentage of neutral fat was below 50

Growth Promoting Factor in Tumor Tissue.—Experiments made by Chambers and Scott showed that a substance is produced from tumor cells during autolysis which in vivo causes an appreciable increase in the rate of tumor growth. The substance is formed under conditions which preclude its being a living agent. It is a fairly stable chemical body which is apparently derived from the nuclear structures.

Effect of Methylene Blue on Body Temperature.—The figures obtained by Stammers indicate that no abnormal fluctuations in temperature occur as a result of the injection of methylene blue in rats.

Search for More Efficient Prophylaxis Against Tuberculosis F Cevey. —p 53
*Pathogenesis and Treatment of Seasickness R Ribolla —p 59.

Seasickness.—Ribolla believes that seasickness is a functional disturbance due to the hyperemia of the vestibular apparatus, produced by the constant changes in the position of the body on the ship in movement (movements which have an opposite direction in pitching and rolling), by which at first the semicircular canals and the endolymphatic liquid simultaneously follow the movements of the body and that when they have a movement in the opposite direction the endolymphatic liquid continues to be carried in the direction produced by the first impulse, and then goes inversely to the movements of the semicircular canals, which follow all the movements of the body. In this way, the endolymph is made to impinge on the ampullae of the semicircular canals, producing vertigo. Movements of the ship will excite different semicircular canals, especially of the superior and posterior canals (rolling and pitching). Excitation and hyperemia of the vestibular apparatus produce a reflex vertigo, with exaggeration of the activity of the pneumogastric nerve (vagotonic state). In these conditions, the best remedies are those which act as sedatives to the vagus, and tampons producing ischemia introduced into the external auditory meatus.

*Intoxication Following Use of Coal Tar Paints. T. A. Kidston.—p. 188.

Coal Tar Paints Cause Poisoning.—Kidston describes a new form of intoxication encountered among painters and laborers engaged in applying coal tar preparations to the inner walls of confined spaces. The premonitory symptoms complained of were in most cases few and mild. Onset was sudden and almost unperceived. The first symptoms were dizziness, lacrimation, gastric malaise, nasal irritation and muscular weakness. At no time was there any dermatitis or any symptom of bronchial or gastric irritation. Examination of the urine of five patients on the day after the intoxication revealed no albuminuria. Coal tar naphtha was found to be the cause of the illness. The effects are mild and temporary, causing no ill to the human system.

*Treatment of Puerperal Insanity. P. Lalor.—p. 247.

Intra-Uterine Transplantation of Ovary.—When double salpingectomy is unavoidable in patients who desire to retain the possibility of childbearing, Monson advocates intra-uterine transplantation of the ovary. His experiments on rabbits show that the ovary with its blood supply intact can be transplanted successfully into the cavity of the uterus. Microscopically, the ovary is seen growing in the uterine mucosa, but it is in a state of delayed activity, as evidenced by the absence of graafian follicles, but there are clusters of primordial cells and here and there primitive young follicles. There is some atrophy of glandular elements of the uterus and slight round cell infiltration.

Vaccinotherapy of Puerperal Insanity.—Ten cases of puerperal insanity have been treated by Lalor with vaccines. Two series of vaccines were used. No. 1 series contained 20 million *Bacillus coli-communis* and 120 million *Staphylococcus aureus* in each 0.2 cc. An initial dose of 0.3 cc. was given by hypodermic injection. In four days an increased dose of 0.6 cc. was given, and so on at intervals until 1.5 cc. had been given in a dose. After an interval of a month, if no result was obtained or if the result was insufficient, a second course of no. 2 series was given. The vaccine of no. 2 series was of the same composition as that of no. 1 series, but was made up to twice the strength. The same doses and the same intervals were used in the second course as in the first. The results from the treatment are said to have been very good.

*Transmission of Typhoid Fever by Bedbugs. Lynn-Ge.—p. 62.

Vitality of Plague Bacilli.—The vitality of *B. pestis* has been studied by Jettmar. Intensive fixation by passing through the flame does not kill the bacilli in thin smears from a plague bubo. Even short fixation by alcohol after passing through the flame does not kill with certainty. Preparations stained with diluted carbolfuchsin may still contain living plague bacilli even when treated previously with alcohol for a short time. By staining with concentrated alkaline methylene blue, the bacilli seem to be killed. The wash from the stained plague smears may contain plague bacilli. It has, therefore, to be disinfected, as well as the filter paper that has been used for drying the stained preparations.

Transmission of Typhoid by Bedbugs.—Lynn-Ge has determined experimentally that typhoid can be transmitted by bedbugs, but two conditions are essential to infection: (1) The blood which the bedbugs suck must contain a large number of typhoid bacilli; (2) numerous bedbugs must bite the healthy animal.

*Benzoin-Cholesterol Test for Syphilis. V. E. Badoux.—p. 21.
*Differential Diagnosis of Nodular Syphilis. Dumollard.—p. 42.

Benzochol Test for Syphilis.—Badoux tabulates the comparative findings with the Wassermann, Sachs-Georgi and Vernes tests and the Sachs-Klopstock benzoin cholesterol (benzochol) method in 264 subjects. He applied the tests to 221 syphilitic serums, 40 tuberculous, 3 from leprosy, and 221 free from syphilis. The reactions harmonized well in the syphilitic serums. The benzochol reaction appeared more sensitive than the Sachs-Georgi, and as specific as the Wassermann or Sachs-Georgi. The test is simple and rapid, but the instability of the benzochol solution deprives this reaction of practical value. The antigen property of the solution seems to vanish in two or three months.

Lupus and Nodular Syphilis.—Dumollard found all the signs testifying to lupus in the case described, even to the findings under pressure with glass. But under tentative treatment as for syphilis the "lupus" rapidly melted away.

False General Paresis in Tabes. Gougerot et al.—p. 107.
*Gumma as Primary Sore at Reinoculation with Syphilis. Montpellier.—p. 141.

Gumma as Primary Lesion from Syphilis Acquired in Congenital Syphilis.—Montpellier reports a case of genital syphilitic gumma, appearing about fifteen days after contamination. This occurred in a native of Africa with congenital syphilis, aged 30. It is probable that chancriform gummas may appear as the result of specific reinfection. This may be especially noted among the nontreated natives. The extreme allergy of the syphilized organism explains why reinoculation induces in them only a local tertiary lesion, of highly allergic type, namely, the gumma. On the other hand, this may also explain the rarity of the localization of the spirochetes in the central nervous system among the natives.

Existence of a Myometrial Gland in the Human Uterus (25 Photomicrograms). H. Keiffer.—p. 684.

The Campaign Against Syphilis in Belgium.—Bayet presents the results accomplished in Belgium since the Armistice as a brilliant success. At the close of the war the disease had spread to the remotest villages and drugs to combat it were distributed through 300 clinics and dispensaries, but it was not until August, 1920, that a concerted effort was made for systematic drug prophylaxis on a large scale. As the arsenicals cause the rapid healing over of the open lesions of syphilis, this double cicatrizing and microbicidal action reduces the contagious stage of syphilis to a fourth or a fifth of the former duration of the infectious phase. This is equivalent to reducing by 75 or 80 per cent the number of sources of infection. The universal distribution of the disease compelled universal provisions for combating it, and the national public health service called on every physician in the realm for aid. The state supplied the drugs free to every person affected with syphilis, and medical treatment was given free also, the state reimbursing the physicians for their assistance in administering the drugs. In this way, treatment was accessible to all and the entire profession throughout the country collaborated in the work. The state paid out 1,400,000 francs annually for the drugs during the first years, and paid the expenses of the numerous preventoriums established.

In the Scandinavian countries, every syphilitic is compelled to continue treatment until completely cured, under penalties up to imprisonment. But these measures are too drastic for Belgium, and the reliance had to be on measures to persuade and remind the syphilitic of the necessity for overcoming their inertia and continuing treatment as long as necessary. The Antivenereal Peril League conducted an intensive campaign with posters, meetings, pamphlets, moving pictures, reaching directly nearly a million and a half persons and rallying to the service 250 different organizations of various kinds; 100 lecturers delivered 2,250 lectures, during the three years, to audiences totaling 562,500. The work of the Antivenereal Peril League was thus an indispensable complement to the work of the state in the campaign, but the country doctors deserve special credit for searching out cases in the remotest regions. The proportion of new cases to the total syphilitics dropped from 25 per cent in 1920 to 12 per cent in 1923, in Brussels, from 23 to 9 per cent; at Antwerp, from 34 to 16, and at Liége from 34 to 12 in 1924. In no other country have the results been so decisive as in Belgium except in the Scandinavian countries. The propaganda made by the league was not on moral grounds but a propaganda of facts, bringing the secret diseases out into the open, proclaiming their dangers, and posting everywhere the addresses of places where they could be cured free of cost. Most of the new cases encountered now are imported.

Treatment of Fractured Leg.—Stassen clears out the focus thoroughly, sutures, and immobilizes in a Laurencet pad, and has the patient sit on the side of the bed with his legs hanging loose. He is encouraged to move his toes, ankle and knee, repeating the pendant legs active movements day after day. The soft parts are repeatedly punctured to allow escape of lymph and blood; more than a liter of fluid may drain away in the first two days. In none of his fifteen cases treated on these principles was the temperature above 37.5 C. and it was constantly below this after the second day. The operative wound healed by primary intention, and consolidation was complete in three to six months, although in some cases the roentgen rays had shown an actual mosaic of splintered and crushed bones.

*Suprarenal Melanodermia M. Loeper et al.—p. 283.

Familial Elective Localization of Syphilis.—Flandin reports five cases of syphilis with identical localization in members of the family: syphilis of the aorta in two brothers and the wife of one; in husband and wife, and in father and son; also hemolytic jaundice, from congenital syphilis, in father and two daughters. In his opinion, the syphilitic virus is single; its localization may depend on a hereditary predisposition, rendering certain tissues or organs more vulnerable, so that they become the elective seat of the spirochetes. The identical form of syphilis in husband and wife may possibly be explained by the same food and conditions of living, inducing in them similar properties, entailing analogous reactions to a morbid agent. The specific treatment cannot modify the tropism of the spirochete in the contaminated subject, but it may modify it in the one transmitting the infection.

Secondary Angina Pectoris.—Weissenbach and Kaplan describe a case of infarct of the myocardium, inducing a condition of angina pectoris in a man, aged 62. The characteristic pain was located not only in the whole of the thorax, but also in the arms, neck, jaws and upper part of the abdomen. The pain was extremely severe and persisted for eight days, until death. The extreme severity of the pain and its unusual extent were the predominant clinical features, suggesting in this, as also in two other personal cases, the diagnosis of infarction in the myocardium.

Suprarenal Bronzing and the Sulphur of the Blood.—Loeper, Decourt and Ollivier conclude from their experimental and clinical study of suprarenal melanoderma that melanin is an amino-sulphurous substance. The suprarenals retain the sulphur; and therefore obliteration or removal of these glands increases the amount of sulphur in the organism. The high sulphur content of the blood with melanoderma suggests that it may be a factor in the pathogenesis of the pigmentation.

Intracutaneous Vaccination Against Anthrax.—Nevodoff applied this method in 4,092 animals. Cattle were injected intradermally with 0.6 cc. of the anthrax vaccine, horses with 0.4 cc. and calves with 0.2 cc. The nodule, appearing at the place of the injection, subsided in three or four days. The vaccination did not induce edema or general reaction, and therefore the usual work of the animals was not interrupted. No cases of anthrax were noted among the vaccinated. A second injection of the vaccine in twenty cattle testified to the substantial immunity conferred by the first injection, as there was no reaction of any kind to the second. The Besredka technic was strictly followed.

Conservation of Insulin.—In Choay's experiments the insulin retained its potency for about two years after its preparation; and for nineteen months in solution.

The Serologic Symbiosis Between Mother and Fetus.—Hirszfeld and Zborowski say that infants with the same blood group as the mother weighed from 3,200 to 3,500 Gm. soon after birth. The weight of the infants with a blood group different from that of the mother, was from 2,900 to 3,200 Gm. Further observations suggested that considerable difference in the blood groups of husband and wife may arrest the development of the fetus or even impede fecundation. Extreme serologic differences might even be the cause of sterility in certain marriages.

Action of Atropine on Stomach Function.—Mitrovitch reiterates that atropine usually reduces the acidity of the gastric juice, also the pepsin content. It retards the evacuation of the stomach contents. The action of pilocarpine on the stomach is analogous to that of atropine, although the mechanism is different.

Treatment of "Low" Gonorrhea in Women. J. Janet.—p. 231.
Marginal Glossitis Exfoliativa. G. Rimé.—p. 235.

Multiple Intolerance for Drugs Used in Treating Syphilis.—Gougerot has observed cases of intolerance not only for arsenicals or mercury or even of bismuth; but for two or all of these drugs. The cause of this "polyintolerance" is so far not established. Most of the by-effects are of the anaphylaxis type, as, for instance, arsenical or bismuth shock or erythrodermia. There are also phenomena of saturation, such as toxic arsenical neuritis, or lesions of the liver, an arsenical purpura. The intolerance may be tardy, appearing not before the end of one or repeated series of treatment; sometimes not until three or four years after the specific treatment. The intolerance may occur rapidly, at the second or third injection; it may be total, so that the patient cannot bear any preparation of the drug; or partial, intolerant only to certain brands. In this case the doses must be decreased; sometimes by a half. After suspension for a time, the drug may be resumed, starting with very small doses, and gradually increasing them. Vaccinating doses, given one hour before the normal dose, were beneficial in two patients. Antitoxic and antianaphylactic substances may be effectual. In rebellious intolerance to each of the most important drugs, less powerful antisyphilitic remedies, now unpopular, may have to be used.

Unsystematic Treatment of Syphilis.—Milian declares that there has been no reduction in the number of new cases of syphilis. He encounters as many nowadays as in 1919. This is due in part to the afflux of foreigners, especially from the African colonies, where nearly every one has syphilis. But it is due in large part also to the anarchy that prevails in the treatment of syphilis, the diversity of drugs, of doses, of routes, and the length of treatment. He reiterates that physicians are forgetting what a serious disease syphilis is; they are confident that it can be easily cured and with mild courses, and they trust too implicitly that negative serologic tests imply a cure.

*Gastric Hyperacidity and the Motor Function. P. Le Noir and R. Sarles.—p. 292.
Eye Complications of Sinusitis. R. Clément.—p. 293.

Hyperchlorhydria and Motility of the Stomach in Men and Women.—Le Noir and Sarles' tests were made on 100 men and 100 women with excessive acidity of the stomach. It seemed to be accompanied by reduced motor functioning more frequently than with exaggerated motility; associated hyperactivity of the mucosa and muscles was noted in only 10 per cent of the men, and only exceptionally in women. Depressed motor functioning of the stomach seemed to be a common phenomenon in women, even in those with hyperchlorhydria. Timbal has emphasized that women suffer less from gastric hypertonicity than men. Hurst also has noted a higher percentage in men of cases of hypervagotonia and a consecutive duodenal ulcer than in women.

*Fistulas Between Stomach, Jejunum and Colon. R. Appelmans.—p. 757.
*Kienböck's Disease. R. Fontaine.—p. 769.

Simple Wounds of the Spinal Meninges.—In the six cases on record, the three with meningitis terminated fatally. With escape of cerebrospinal fluid, an epidural injection may compress the leaking point, and copious intravenous infusion may aid in restoring the normal balance. With hypertension of the fluid, concentrated sugar solutions by the vein and mouth may be useful. These and a new case are summarized, with the present status of the three patients surviving to date.

Gastrojejunocolonic Fistula.—Both patients recovered after surgical correction of the fistula, in Applemans' two cases.

Traumatic Atrophy of the Semilunar Bone.—In Fontaine's case of Kienböck's disease, the young man had injured the semilunar bone in catching a brick thrown to him in unloading. Atrophy and softening of the bone had incapacitated him, but all disturbances ceased after removal of the semilunar bone. Müller obtained good results in a case of this kind by scraping out the bone, keeping the shell of the bone.

The Oscillometer in Obstetrics.—Balard records the arterial pressure and the oscillometer index in normal pregnancy, in labor and after delivery, also in incoercible vomiting and suprarenal insufficiency, and in pregnancy toxemia, albuminuria, eclampsia and retroplacental hemorrhage. He specifies the influence on arterial pressure of pulmonary affections, and cardiac insufficiency, during the puerperium, and the changes of arterial tension under anesthesia, obstetrical hemorrhages or shock and puerperal infections. He reiterates that determination of the arterial tension and the oscillometer index is valuable not only in prognosis, but as a guide and control for treatment. He summarizes the findings in eighty women, using a Pachon oscillometer, as a simple and reliable method for testing the blood pressure.

*Mediastinal-Pulmonary Lymphosarcomas. C. Roubier.—p. 587.
*Pregnancy, Protein Shocks and Biliary Colic. G. Parturier.—p. 614.

Lymphosarcoma in the Thorax.—Roubier refers to a group of cancers starting in mediastinal glands and invading the lung early, spreading to the lung, without compressing organs on the way. The clinical picture is that of a chronic pulmonary disease without appreciable mediastinal symptoms. These lymphosarcomas run a rapid course; exploratory puncture may bring pus from a cavity which may mislead the diagnosis, as occurred in one of the three cases described.

Biliary Colic in Relation to Pregnancy.—Parturier analyzes various published statistics and his own experience with twenty-six cases of biliary colic in women. In 11.5 per cent, symptoms from the biliary apparatus appeared for the first time during a pregnancy; in 88.5 such had preceded the pregnancy and reappeared afterward, but the gestation period was free from them. Biliary colic reached its maximum incidence in the postpartum period. Widal has recorded the same in regard to asthma, and Lépine in regard to epileptic seizures. Parturier thinks that this can be explained by a kind of postpartum shock. Wallich called attention in 1907 to this sudden postpartum depression, drop in the arterial pressure and temperature, and extreme weakness, the whole sudden in its onset and transient. It seems to be a kind of anaphylactic shock as the ovary resumes its external function after the long rest. This increases the analogy between liver colic and protein shock.

*Ureteral Calculi. E. Leo.—p. 193.
*Bladder Calculi. M. Negro.—p. 223.
*Perineal Urethral Fistula. R. Botteselle.—p. 256.
*Suture After Pyelolithotomy. G. D'Agata.—p. 267.

Ureteral Calculus.—Leo's experience with the four cases described demonstrates the importance of prompt intervention, and that the stone in the ureter can be easily reached, through a small incision, by the abdominal extraperitoneal route. The ureter is usually dilated above the obstruction, so that the calculus can be easily pushed up to allow readier access. There were no pathognomonic symptoms but the roentgen findings were conclusive.

Bladder Calculi.—Negro insists that neither cystoscopy alone nor roentgen examination alone can be relied on in diagnosis of bladder stones, but the two combined are remarkably instructive.

Perineal Urethral Fistula.—Six illustrations show the technic and fine outcome of Botteselle's flap method for reconstruction of the urethra.

The Suture After Pyelolithotomy.—D'Agata's research on dogs has confirmed his clinical experience that a longitudinal incision in the posterior wall of the pelvis does not require suture as it will heal spontaneously. If the stone is so large that the incision has to form an obtuse angle—which gives much more room than a straight incision—then conditions do not favor so well the smooth flow of urine, and spontaneous healing cannot be relied on.

Chirurgia degli Organi di Movimento, Bologna

10: 1-208 (Dec.) 1925

*Paralysis from Reduction of Dislocation. C. A. Velo.—p. 1.

*Improved Technic for Sympathectomy. U. Camera.—p. 195.
Correction of Pes Equinus. U. Stoppato.—p. 199.
*Disease of the Hip Joint. F. Delitala.—p. 204.

Paralysis After Reduction of Congenital Dislocation of the Hip Joint.—The bilateral deformity was corrected by manipulations alone in the girl, aged 10. But paralysis of both legs followed, persisting for seven months. Velo ascribes it to stretching of the sciatic nerve during the maneuvers. In 110 other nonoperative cases, the reduction was complete and permanent, without mishap.

Correction of Spastic Talipes Equinus.—Camera extols the theoretical and practical advantages of implanting a wedge of bone to spare the tendons from unnecessary strain.

Congenital Dislocation of the Patella.—Zanoli gives an illustrated description of sixteen cases and discusses the outcome under the different methods of treatment that have been proposed. His preference is for transplantation of the patellar tendon and suture of the capsule.

Improved Technic for *Periarterial Sympathectomy.*—Camera injects a simple saline solution between the adventitia and the muscular layer of the artery. The fluid loosens and detaches the adventitia, so it can be easily stripped off.

Hip Joint Disease.—The diagnosis wavered between osteochondritis, preceding coxa plana, and a tuberculous process. Tuberculin tests were negative, and the course of the case has apparently sustained the reliability of the biologic tests for the differential diagnosis.

Medicolegal Experts. E. Mariotti.—p. 208.
Epithelioma of the Middle Ear. M. Galli and E. Di Lauro.—p. 212.

Tuberculosis and Cancer.—Centanni and Rezzesi studied on animals the question of the antagonism between cancer and tuberculosis. Their mice were resistant against the tubercle bacilli. Injection of a mixture of cancer cells and living bacilli produced no tumors. Simultaneous injection in a different part of the body depressed the development of the tumor, although in some of the mice only temporarily. Previous infection of the animals with tubercle bacilli delayed the development of the subsequently inoculated tumor. Injection of bacilli into the tumor partially destroyed it, but some of these animals died under toxic symptoms. Dead bacilli had no influence in parallel experiments. Tuberculin mixed with the emulsion of the tumors retarded or inhibited its growth.

Hemocrasic Insufficiency of the Liver.—Brugi regards incomplete or absent retraction of the blood clot as one of the most constant symptoms of diseases of the liver. A low number of blood platelets is another sign. The prolonged bleeding time is more frequent in liver diseases than a prolonged coagulation time.

Pancreas Cysts. P. Escudero et al.—p. 342.
Present Status of Etiology of Cirrhosis of the Liver. Heidenreich.—p. 357.

Visualization of Fistulas Between Liver and Bronchus.—Escudero and his co-workers found it impossible to get the opaque fluid into the fistula by intratracheal injection. They then punctured the hydatid cyst in the liver, aspirated 10 cc. of pus, and injected the same amount of lipiodol into the cyst cavity. The iodized oil passed into the fistula and bronchus as the patient was placed in the Trendelenburg position. Several of the instructive roentgenograms obtained by the retrograde procedure are reproduced. This and other experiences have convinced them that the method is entirely harmless.

Digestive Disturbances with Calculi in the Kidneys.—The neurasthenic young woman in the case described had calculi in both kidneys, and there was downward displacement of all the viscera. This congenital splanchnoptosis of the Stiller type explained the tendency to phosphaturia and phosphate calculi, from mechanical interference with function. It also explained the digestive disturbances from the same mechanical factors.

Archivos Españoles de Pediatría, Madrid

9: 705-768 (Dec.) 1925

*Prepuberty Obesity in Children. G. Marañon.—p. 705.
Pathogenesis of Whooping Cough. R. Duarte Salcedo.—p. 725.

Obesity in Children.—Marañon emphasizes the necessity for thyroid treatment in every case of obesity in a child with metabolism of 5 per cent below normal. This group includes nearly all the cases of obesity before puberty, and thyroid treatment is scientifically justified. The thyroid treatment not only reduces the weight as the abnormal fat melts away, but the sex characters assume a more normal type, with descent of the testes and loss of the eunuchoid aspect. The transformation in the child's appearance is sometimes remarkable in its promptness and completeness. Ovarian treatment may prove a useful adjuvant in girls. In twelve cases in children between 8 and 15 the metabolism rate ranged from zero to minus 35 per cent. Unless normal conditions are restored in time, the child is doomed to sterility and impotence.

*Present Status of Serodiagnosis of Syphilis. E. Cervera.—p. 244.

The First Medical Book Published in Mexico.—León describes a book printed in Mexico in 1570 of which only three copies are extant, one in the Lenox collection of the New York Public Library. The author was Dr. Francisco Bravo, who practiced in Spain before settling in Mexico. The title is "Opera Medicinalia," and the work contains a number of wood engravings.

Serodiagnosis of Syphilis.—Cervera relates that the concordance was perfect with the Wassermann and flocculation tests in 163 of 187 syphilitic or suspected serums. In the twenty-four in which the findings with the various tests did not harmonize, the Kahn technic seemed to be less sensitive than the other tests. This unreliability was especially noticeable when compared with the Kolmer and Hecht technics.

Regulation of Wet-Nursing. M. González Alvarez.—p. 333.
Heliotherapy for Children. Tolosa Latour.—p. 342.
*Foreign Bodies in the Appendix. M. Milano.—p. 350.
*Enlargement of Liver and Spleen in Boy. Castro Emia.—p. 357.

Foreign Bodies in the Appendix.—Milano describes the cases of three boys, aged 7 to 11, who presented subintrant attacks of appendicitis. There was no hyperleukocytosis, but otherwise the attacks were typical. The appendix was found much dilated; one contained a raw bean in good condition. In the second case a shot had served as a nucleus for a concretion of fecal matter in the appendix. In the third case the appendix was full of grape-stones and had burst, but an adhesive process of localized peritonitis had walled in the escaping grape-stones and pus.

Enlargement of Liver and Spleen with Jaundice and Normal Leukocyte Count.—The three sons had presented this clinical picture; the girls seemed to be healthy. Great improvement was realized by treatment as for syphilis although there were no signs of syphilis in the family. The two older boys had died without reaching the age of the one treated in this way in his ninth year.

The Orientations of Modern Medicine. I. Chávez.—p. 1109.

Nevus Carcinoma.—In González' case the small flat brownish nevus on the cheek from childhood began to grow as the woman reached the age of 48, forming a small tumor, bleeding readily and rebellious to application of household remedies, and finally suppurating. There was no involvement of glands. The microscopic diagnosis was melanic carcinoma, and the whole retrogressed under three sittings of negative electrolysis. The needle was passed down to sound tissue, at eleven points horizontally and eleven points on a vertical line; it was left in place for three minutes each time, while a 6 milliampere current from a dry battery was turned on. The positive pole was placed on the back. The procedure was repeated in two weeks, making the punctures at the outer edge, and a few weeks later the final application was made. The illustrations confirm the complete subsidence of the tumor in three months.

International Congress on Penitentiaries, 1925. E. Gómez.—p. 719.

The Remissions in General Paresis.—Cisternas comments on the 54 per cent of remissions said to have been realized with malaria treatment of general paresis. In his own experience, the Hospicio de las Mercedes received an average of 241 general paresis cases during a recent ten year period, and an average of 18.67 per cent were discharged on account of remissions enabling them to resume their ordinary life. He explains, however, that besides the forty-five discharged, another twenty might have been discharged but on account of home conditions were retained in the infirmary. This brings the percentage of remissions much closer to that of the malaria treatment, especially when it is considered that the material is not restricted to selected cases, and that early cases do not reach the infirmary. The remissions observed at the infirmary are as complete as those after malaria treatment. In order to estimate properly the actual status of the latter, the statistics of remissions should group separately the early and the old cases.

Complications of Artificial Pneumothorax.—Viton discusses therapeutic pneumothorax from all angles, especially the indications and the mishaps with it, emphasizing that we must not fear it too much nor be overconfident with it. A pleural effusion developed in 25 per cent of his fifty-eight cases. He ascribes this small proportion to the fact that he uses air instead of nitrogen for the insufflation. Fourteen of the fifteen with this complication were women. In three cases there was amaurosis for a few minutes to eight hours, indicating gas embolism, but it subsided then harmlessly. He has never encountered an instance of pleural shock from the puncture alone, but in one case, after three insufflations, intense dyspnea developed from a spontaneous pneumothorax, with a secondary valve formation, and the pleura kept filling up with air, fatally suffocating the patient, notwithstanding continuous aspiration of the air by reversing the apparatus. In one man of 60 the pneumothorax had been borne well and the condition had improved, when symptoms of heart failure developed, with somnolency and edema, and he died the thirty-third day. Adhesions pulling on the right auricle or aorta induced heart symptoms in a few patients, compelling interrupting of the pneumothorax. One woman developed uncontrollable vomiting, although the pulmonary lesions had improved remarkably under the collapse treatment. The maximal intrapleural pressure had evidently been responsible for the vomiting and also for the fine and permanent therapeutic results. With pleural effusion complicating the collapse therapy, he punctures if the effusion is not promptly resorbed. If it becomes purulent, it must be drained, bearing in mind that the streptococcus is more dangerous than the pneumococcus. Tuberculin is an important aid in these complicating pleural effusions. When the pleura is inflamed, it absorbs the gas less rapidly. Twenty instructive cases are described in detail. One case teaches the evil consequences of allowing a tuberculous pleurisy with effusion to run its course without puncture, under merely expectant treatment. The resulting adhesions prevent therapeutic pneumothorax later.

Elimination of Phenolsulphonphthalein in Normal Children.—Casaubón and Winocur applied this kidney function test in forty normal children over 6 years old. They injected the stain intramuscularly, twenty to thirty minutes after the child had drunk 200 to 300 cc. of water. The urine was then examined an hour and ten minutes afterward. The extreme range of elimination was from 50 to 85 per cent (one case each). In 52.5 per cent the figure was 66, and the average of all was 69 per cent. They regard these figures as the normal standard for all except very young children.

Antiscurvy Value of Milk.—Reyher never observed scurvy in guinea-pigs fed with human milk. They died of inanition. The antiscorbutic value of cow's milk depends on the fodder. Boiled milk of an originally high vitamin content may give better results than raw milk with a low content.

Sugar Determination in Milk.—Bruhns comments on the marked difference between the results of determination of sugar by reduction or polarization in human milk. There may be some other polysaccharids present. Cow's milk gives identical results with both methods.

Ulcer Pain and Visceral Sensibility. L. Hirschberg.—p. 423.
Influence of Bile on Movements of Colon. H. S. Lurje.—p. 429.

Pituitary Extracts and the Stomach.—Schoendube and Kalk have been studying the motility of the stomach in man and animals. Pituitary extracts have a double phase of action: the tonus and peristalsis are diminished at first and increased later. They believe that the sympathetic is irritated in the first phase, the Auerbach plexus in the second. They do not believe that histamine is responsible for the action. In direct observations on animals, the first phase was associated with a local anemia.

Cholesterol in Bile and the Food.—Salomon and Silva found even in long periods of a diet free from cholesterol the elimination of a few milligrams of cholesterol by the bile.

With a diet rich in cholesterol, the elimination was much larger without reaching the amount ingested. This occurred especially after previous deficit of cholesterol.

Edema and Water Production.—Mello points out that water forms in the body by addition of oxygen from the air. Therefore the weight of the patient may increase although the weight of urine and feces surpasses that of the intake of food and fluid. This—and not the restriction of insensible perspiration—accounts for the occasional gain in weight of fasting nephrectomized and of hibernating animals, as well as for many clinical observations.

Ulcerative Colitis.—Grossfeld makes a phenolized autovaccine and injects subcutaneously 1, 2 and 3 cc. of a suspension containing 100 millions of germs per cubic centimeter. The intervals are from three to six days—according to the general reaction. After this he injects the same volumes of an emulsion containing 1 billion germs per cubic centimeter. He interposes milk injections if the fever reaction is too weak. The diet should consist chiefly of proteins—not of vegetables.

Heredity in Colloid Goiter. K. H. Bauer.—p. 512.

Roentgen Treatment of Laryngeal Cancer.—Prinz treated with roentgen rays two patients with histologically diagnosed carcinoma of the larynx. One of them died almost six years afterward from an intercurrent disease. The larynx was healthy. The other—a young woman with metastatic infiltration of lymph nodes—is clinically healthy after six years, and has borne a child.

Head's Zones in Abdominal Diseases.—Gaza confirms the presence of hyperalgetic skin zones or patches in organic abdominal diseases, but only shortly after a severe colic. The majority of the zones of hyperalgesia are due only to functional disturbances. Dermographism, spastic colitis and dysmenorrhea are common in such patients.

Vital Staining of Sarcoma.—Gaza injected trypan blue and lithium carmine into a sarcoma of the tibia. Only the fibroblasts and macrophages of the stroma accepted into their cytoplasm the dye injected—not the living sarcoma cells. Diffuse staining of the cell indicates its death. Only such cells were attacked by leukocytes and macrophages.

Urethritis (Male) from Larvae of Niptus Hololeucus.. Sternberg.—p. 271

Extensive Gangrene of the Scalp After Bleaching the Hair.—Von Berde gives an illustration of the gangrene of the entire back of the head in a woman of 26 who had had her red hair blondined by a professional hairdresser ten days before. The woman had long been subject to eczema. The label on the empty bottle specified 30 per cent hydrogen dioxide. The woman wore a felt hat home, thus steaming the region further with the fumes of the chemical while the braids of hair were pressed by the hat on the irritated scalp. The pain was so severe as the woman walked home that she fainted. The region healed over in the course of three months, leaving a cicatricial bald area, 9 by 10 cm. in size.

Enteritis from Bismuth Poisoning. — Severe ulcerative enteritis developed after a course of seven intravenous injections of a bismuth preparation. The patient was a young woman with spirochetes in a throat lesion and positive Wassermann reaction. The syphilitic lesions subsided under the bismuth, and the intestinal process healed in another month. There were no manifestations of a toxic action from the bismuth outside of the intestines. Fischer theorizes that the bowel must have contained an unusual amount of hydrogen sulphid on the day of the last injection, and this entailed elimination of exceptional amounts of the bismuth through the bowel walls.

Vitamins E. Nassau.—p. 383. C'cn.

Provocation of Occult Bleeding.—If the tests for occult bleeding are negative in spite of a suspicion of an ulcer in the stomach or duodenum, Boas recommends provocation by heat. He applies to the epigastrium, with short intervals, a hot (not warm) dressing every twenty minutes for two days. The method has also therapeutic value.

Experimental Cancer.—Erdmann injected rats with india ink and filtrates from Flexner-Jobling carcinomas. Some of these animals, as well as those in which the filtrate had been substituted by the tumor residue treated with chloroform, reacted with tumors. She also observed that peculiar endotheloid round cells emigrated from the spleens of normal animals cultivated in the plasma with tumor extracts. Such cells were not found in spleens from animals with tumors She concludes that there is a close relation between tumors and the endothelial apparatus. The tumors take better if the latter is blocked.

Sterilization with Arsphenamine.—Prigge found extremely rarely spirochetes in the brain of mice after spontaneous recovery from recurrens and never after sufficient doses of neo-arsphenamine. Buschke's divergent results were due to the subtherapeutic doses he used. In such animals the spirochetes are present not only in the brain, but also in the blood. He found no indication whatever of any lowering of the immunity by arsphenamine in mice infected with recurrens nor in syphilitic rabbits.

Gastrospastic Syndrome. K. Ochsenius.—p. 315.
*Scarlet Fever and Measles. F. Szirmai and B. Jacobovics.—p. 331.

Congenital Syphilis and Irritation.—Fischl publishes evidence for the first localization of manifestations of congenital syphilis in irritated parts of the skin. Staphylomycosis furnishes an especially clear example in its interrelation with syphilis.

Incubation of Tuberculosis.—Epstein found in children—without regard to age—an ante-allergic period of three to seven weeks with intracutaneous or subcutaneous tests, and of four to ten weeks with the cutaneous method. This constancy of the incubation period in man differs from that in animals, where it varies in inverse proportion with the doses of infecting material. There were no other symptoms in these children except the tuberculin reactions.

Etiology of Scarlet Fever and Measles.—Szirmai and Jacobovics repeated the work of di Cristina and Caronia and their collaborators. They regret to be unable to confirm any of their claims. In spite of this, they are not yet convinced of their futility, because of the absolute good faith of the latter authors, and because of their results in prevention of scarlet fever and measles.

Medizinische Klinik, Berlin

22: 279-316 (Feb. 19) 1926

*Syphilitic Aortitis. C. Bruhns.—p. 279.

Combating the Predisposition. L. Gelpke.—p. 300.
Cancer and Its Treatment. O. Strauss.—p. 302. C'cn.

Syphilitic Aortitis.—Bruhns examined 200 syphilitic patients who had been infected from four to forty years before. He found that 23-38 per cent of them had an unsuspected syphilitic aortitis. Early and energetic treatment is indicated.

Toxic Injury from Cactus Spines.—Löwy observed local deforming arthritis and nervous changes in a finger which had been injured by thorns of a cactus.

Menstruation in Hay-Fever.—Joachimovits confirms the occurrence of menstrual disturbances in hay-fever.

Quinine Resistant Lipases.—Löwenberg and Kwilecki confirm the almost constant occurrence of a quinine-fast lipase in the blood with inflammation of the gallbladder or liver, or grave nephritis. The majority of patients with cancer metastases in the liver, or liver congestion, and two out of eight pernicious anemia patients also gave positive findings. Other acute and chronic abdominal diseases—with few exceptions—gave negative results.

Irradiation of Food. I. Serebrijski et al.—p. 716.
*The Vaginal Flora. G. Soeken.—p. 727.

Temperature in Incubation Period of Measles.—Orel recorded the temperature in twenty-six children who had been infected by contact with measles patients. It was normal in the majority of them at the time of the infection as well as later, in the incubation period. Other causes were responsible for the higher temperature in some of them.

Injury from Lack of Water in the Breast Fed.—Hirsch describes the symptoms of dehydration fever which occur most frequently on the third day of life, but may account also for certain postoperative disturbances. The infant's skin is dry, keeps the folds, the tongue is red, granular, resembling corned beef. The mouth is dry, the fontanels, as well as the abdomen, are depressed, the urine and stools dark colored. The voice is hoarse; the infant makes licking movements and drinks eagerly the offered water. Cerebral symptoms, especially vomiting, may predominate—similar to heat stroke—and rectal administration of fluid may become necessary. It should not be forgotten that an infant needs 150 Gm. of water daily per kilogram of body weight.

Sunlight and Vitamins.—Two—probably univitelline—twins had grave rickets notwithstanding a previous diet rich in vegetables and cod liver oil. Vollmer treated them for fourteen days with artificial sunlight reenforced by administration of eosin. The food contained practically no vitamin C. After this he added vitamins to the food of one of the twins. The other recovered under continued irradiation more rapidly than the one with irradiation plus vitamins.

Correlation of Food.—Nassau and Schaferstein show that it is irrelevant to ascertain the significance of single constituents of the food for pathologic intestinal processes, and other disturbances. Only the reciprocal proportions of several elements of the food are comparable. A pure solution of sugar is rapidly resorbed and cannot do much harm. Addition of proteins or, still more, of fat and, most of all, of cow's whey retards the resorption of sugar and favors fermentation. Human milk is indifferent.

Calcium in Breast Milk.—Stransky applied Kramer and Tisdall's method to human milk. He found about 0.045-0.06 per cent of calcium oxide before nursing and 0.025-0.04 per cent after nursing.

Encopresis.—Weissenberg suggests this term—analogous to "enuresis"—for incontinence of stools. The pathogenesis of both is to a certain extent similar. Mental causes predominate—bad dreams and fright. An enema given before going to bed is helpful.

Familial Jaundice and Cirrhosis of the Liver.—Bischoff and Bruhl observed cirrhosis of the liver in three sisters. The splenomegaly, jaundice, and periodically clay-colored stools appeared at the age of 11, and the physical development was retarded. The necropsy findings in the oldest sister are reported.

The Vaginal Flora.—Soeken made vaginal smears from a number of girls. Cocci predominate in children except infants. After the eleventh year, vaginal bacilli were found in the majority. These were never encountered in the absence of all the signs of puberty, but they appeared before menstruation. She found that the complete change of the flora takes place within one week.

*Mushroom Poisoning. W. Steinbrinck and H. Münch.—p. 108.
Chronaxia Determination. E. Blumenfeldt.—p. 147.

Fixation Abscess in Treatment of Sepsis.—Jacob and Wendt injected 2 cc. of oil of turpentine subcutaneously in the side of the thigh. This causes immediately or within two days a painful infiltration which softens in four to twelve days. The abscess should be lanced only if there is fluctuation. They had fine results in pneumococcus and staphylococcus septicemia and in cerebrospinal meningitis of the subacute type. A second fixation abscess is sometimes necessary.

Mushroom Poisoning.—Steinbrinck and Münch deal with the botanical, clinical and therapeutic aspects of mushroom poisoning. Profuse lavage of the stomach and intestine with a suspension of charcoal is indicated, even if the poisoning occurred the day before Remnants of the mushrooms were frequently found with this. Repeated intravenous infusions of 300-500 cc. of 10-20 per cent sugar solutions, with eventual addition of calcium salts, are very useful. Camphor is somewhat dangerous because of the disturbance of liver function, which may prevent its synthesis to glycuronic acid. Caffeine is to be recommended. It is still questionable whether insulin should be added, since mushroom poisoning also entails hypoglycemia.

Zeitschrift für urologische Chirurgie, Berlin

19: 127 252 (March 1) 1926

Cancer of Testicle A Weiser —p 201
Tumors of Scrotum S Rubaschow —p 218
Italian Urologic Congress —p 242

Endocrines After Vasectomy.—Rossi resected the vas deferens in twelve dogs and studied the changes in the endocrine glands thereafter The number of eosinophils in the pituitary as well as the lumen of blood vessels were increased in the first seven months after the operation The follicles of the thyroid and their contents decreased, while the interfollicular epithelia proliferated for about eight months. The connective tissue of the prostate was hypertrophic and the glandular portion atrophic for about the same period. Lymphoid cells accumulated at certain points of it. The testis was swollen for about forty days The inner rows of sperma cells degenerated in the first two months, but the basal row persisted and led to regeneration The spermatozoa never disappeared. There was only a slight increase in the interstitial cells The pineal gland was enlarged only in one of six dogs The parathyroids, mammae and suprarenals showed no changes

Ambard's Coefficient.—Goldberger recommends the determination of Ambard's coefficient in urologic practice. Careful work is necessary

Treatment of Pyelitis.—Pannewitz recommends a sudden change of the actual reaction of the urine in treatment of pyelitis With an acid reaction, an alkalinizing diet and intravenous injections of sodium bicarbonate may help With alkaline reaction of the urine, an acid producing diet, acids by the mouth, and methenamine intravenously should be given.

Localization of Brain Tumors by the Electric Resistance of the Growth.—Lihotzky surveys the further good experiences with A. W. Meyer's rheometric method of detecting brain tumors which are not palpable He measures by means of a needle electrode and Wheatstone bridge the resistance to the electric current. With his apparatus, it was 600 ohms in the brain tissue, 280-320 in the tumor, and 60-80 in the cerebrospinal fluid.

Postoperative Ischuria.—Lampert uses 1 cc. of a 1 per cent solution of pilocarpine in postoperative retention of urine. Intravenous injection is necessary. A necessity for keeping the intestine in repose is a contraindication for the pilocarpine.

*Tuberculosis Campaign and the Practitioner. G. Zickgraf —p. 162.

Tuberculosis Campaign and the Practitioner.—Zickgraf criticizes the prevailing attitude of the central welfare committee. Even the smallest organizations of welfare amateurs and every other possible factor are encouraged to cooperate; the practitioner alone is left out. His duty is only to make the diagnosis. After that, the sanatorium and then the social service will take care of the tuberculous subject. He deplores the propaganda for consideration of hospitals as the only way of good treatment. The patient's opinion on the previous treatment and diagnosis is taken seriously by the hospital physicians—because of their ignorance of real conditions in the world outside—and utilized for transferring responsibility in therapeutic failures to the practitioner. The social service nurses are another factor promoting an antagonism between the practitioner and the patient—not to the advantage of the campaign against tuberculosis.

Right of Privileged Communications and Venereal Diseases. N. Drapkin et al —p 84.

Significance of Lipoids in Serodiagnosis of Syphilis.—Grineff and Baranova conclude from their research that the serologic reactions in syphilis do not depend on chemical changes of the serum, but on the disturbed stability of its elements (proteins, lipoids and salts) affecting the colloid balance The instability of the colloids in syphilitic serums is probably induced by a relative increase of cholesterol, and decrease of phosphatids.

Epinephrine Injections in Relapsing Fever and Malaria.—Mishtchenko recalls Zlatogoroff's epinephrine test in relapsing fever A dose of 0 5 cc of 1:1,000 epinephrine solution is injected subcutaneously in patients with relapsing fever, and the temperature is taken every two hours. If the temperature does not rise, the injection is repeated forty-eight hours later. If the temperature continues within normal range after the second injection, this is accepted as a negative reaction. With a positive reaction, fever occurs within twelve hours after the injection Personal experience has confirmed that relapses need not be feared as long as the epinephrine test is negative. The positive test was most pronounced between the fourth and seventh day following an attack. Contraction of the spleen and consequent expelling of specific spirochetes into the general circulation may explain the positive response to the epinephrine. The test was always negative in cases of reinfection. The epinephrine test was valuable also in diagnosis of malaria treated recently or insufficiently. The mechanism was the same, the expelling of plasmodia into the blood. The injection seemed harmless.

Oral Vaccination in Typhoid.—The method was applied by Solovieff and Gandelsman in places with endemic typhoid fever They used cultures of Shiga bacilli, instead of bile, for sensitization of the intestine. The liquid vaccine contained agar cultures of typhoid and dysentery bacilli, killed by heat There were 70 thousand millions of typhoid bacilli and 30 thousand millions of Shiga bacilli in 5 cc of the vaccine To conserve the vaccine, phenol was added, and peppermint to improve the taste. The vaccine was given fasting; 5 cc. to adults; 2 5 cc. to children below 10; 1.5 cc. to those below 5 No by-effects were noted with this method. The oral vaccination appeared as effectual as the subcutaneous Typhoid developed after vaccination only among those treated during the incubation period. Prophylactic vaccination by this method checked the further spread of the disease.

PROGRESS IN THE TREATMENT OF SKIN DISEASES*

FRED WISE, M.D.
NEW YORK

In the third volume of the *Jahresbericht ueber Haut- und Geschlechtskrankheiten* for the year 1923, edited by Otto Sprinz and printed last year in Berlin, references to the therapy of skin diseases alone numbered approximately a thousand articles, including monographs and books, published throughout the world in one year. These are carefully arranged and classified under various headings, beginning with general therapy and listed systematically to conform as nearly as is possible to the various modalities employed today in dermatotherapy. Among them will be found the following names, most of them hyphenated with the word "therapy"—a list which, if quality and quantity are taken seriously, must strike terror to the heart of the beginner in our specialty: medicinal-, tuberculosis-, organo-, protein-, unspecific blood and serum-, specific serum-, vaccine-, cosmetic-, roentgen-ray-, radium-, artificial light-, sunlight-; high-frequency, diathermy, electrodesiccation and coagulation, electrolysis, refrigeration sympathectomy; to these one might add miscellaneous therapy, including surgery, balneotherapy, psychanalysis, and that form of refined suggestive therapy which induces wealthy, bald-headed men to rest and meditate under an ultraviolet halo. at certain prescribed intervals.

Imposing as this array must seem to the uninitiated, it is a fact that the modern dermatologist is frequently called on to employ one or several of these tools of his calling as routine measures in everyday practice. Compare this with the state of affairs twenty-five or thirty years ago: the old pun about skin diseases falling into two groups—those that ought to respond to sulphur salve and, if they don't, those that *will* respond to zinc salve—gave rise in many a medical meeting to laughter and ridicule, strongly tinged with an undercurrent of belief in the purport of the alleged witticism. Arsenic, I believe, completed the old-time triad on which the dermatologist was supposed to depend for his daily sustenance. But that arsenic even in those days fulfilled its mission is attested to by the occasional reports in old publications of such grave diseases as pemphigus and mycosis fungoides, cured with arsenic.

To one, like myself, who began the study of the specialty before the value of roentgen-ray therapy became generally known, mention of mycosis fungoides recalls a vivid picture of the utter hopelessness with which these patients were formerly regarded. Twenty years ago the victim was admitted to the hospital with reluctance (just as pemphigus patients are today), and often under strong protest on the part of the admitting physician or of the hospital director. Today the patient with mycosis fungoides is given a bed with some show of hospitality; roentgen-ray treatment, although it will not cure him of his disease, will almost invariably rid him of his cutaneous lesions for a varying length of time, stop his itching, permit him to gain in weight and strength, and in many instances prolong his life for years, enabling him to be about and to earn his living, often with very little discomfort.

Roentgen-ray therapy of this disease has changed the status of the victim from that of a hopeless, bedridden sufferer to a more or less hopeful, ambulatory patient, whose chief concern should be that the management and supervision of his malady be in the hands of one who understands mycosis fungoides with all its vagaries, and who is an expert roentgen-ray therapist. The late John A. Fordyce told of two patients whom he had treated in recent years with roentgen rays combined with intravenous arsphenamine injections, who had remained apparently cured during a period of three years, and who had no recurrences up to the time of his death, a year ago.

To cite examples of roentgen-ray therapy as an alleviative measure in this disease, I recall a man with a very extensive eruption, who was treated at the New York Skin and Cancer Hospital about fifteen years ago; his cutaneous lesions cleared up under roentgen-ray treatment, but he died during a period of remission, the necropsy revealing a large sarcoma of the kidney. About eight years ago, a middle-aged woman presented herself at the Vanderbilt Clinic with a widespread, infiltrated psoriasis; a short time later, some of the lesions became more elevated and infiltrated, assuming a dark brown tint; section revealed typical mycosis fungoides. Roentgen-ray treatment has held the disease in abeyance since that time, and although her skin never cleared up entirely, she was enabled to perform her ordinary household duties with comparatively little discomfort, up to the past year. Previous to Roentgen's discovery, this patient would have died miserably, within six months to a year. One of MacKee's patients has been under observation more than sixteen years, during which period occasional recurrences were readily controlled by irradiation.

Closely related to mycosis fungoides, from the standpoint of therapy, are the sarcoma of Kaposi, the leukemias, lymphogranulomas and kindred diseases. In early cases of sarcoma of Kaposi, in which the lesions are relatively small and not numerous, cures have been reported with roentgen-ray treatment, sometimes combined with arsenical medication. In extensive and especially in the long neglected cases which are occasionally encountered in patients immigrating from

---

* Chairman's address, read before the Section on Dermatology and Syphilology at the Seventy-Seventh Annual Session of the American Medical Association, Dallas, Texas, April, 1926.

Russia and central Europe, roentgen-ray therapy, administered in massive doses of filtered radiation, will bring about absorption of infiltrations and tumors, relieve pain and prolong life; so that many of these unfortunates, instead of being bedridden for years and in ceaseless pain and discomfort, as they perforce had to be two decades ago, may now go about their business under relatively tolerable conditions.

In the various diseases of the hematopoietic system associated with cutaneous lesions, roentgen-ray therapy has completely revolutionized the older forms of treatment; although we cannot speak of cures, it is a fact that the judicious employment of roentgen rays as a palliative measure has done more for this class of patients than was formerly accomplished by all other known methods to afford relief. Rhinoscleroma may be cited as an example of a condition which, heretofore regarded as incurable, will today respond very favorably to roentgen-ray and radium therapy. Sigmund Pollitzer, I believe, was the first in this country to report a cure.

The initial therapeutic attack against melanosarcoma and melanocarcinoma of the skin and mucosae should be with roentgen ray and radium; the knife and the electrocoagulation current should be resorted to only after as much as is possible has been destroyed by means of radiotherapy. In the majority of patients with such melanotic tumors, the occurrence of metastases results in death, regardless of the methods of treatment; occasional cures have been reported from roentgen-ray and radium therapy; MacKee reports four cases as cured, without recurrence in from four to ten years after treatment. A few years ago, Howard Fox exhibited a little girl with a sarcoma of the temporal region, about the size of a walnut, which disappeared completely only four days after a single roentgen-ray exposure; the child unfortunately succumbed to metastatic growths a few weeks later.

I will not tax your patience with a recital of the many skin diseases which are amenable to roentgen-ray and radium therapy and in which palliation and cure reflect a very substantial progress in dermatotherapy; the ground has been thoroughly covered by George M. MacKee in his book. But I should like to dwell, for a moment, on advances in the treatment of two conditions especially: juvenile ringworm of the scalp, and angioma. The old treatment of tinea capitis, by means of manual epilation and the constant application of antiseptics, required anywhere from six months to three years to bring about a cure, the child meanwhile being kept out of school. Today, the actual time, by means of the Kienböck-Adamson technic, has been reduced to from seventeen to twenty-one days, the regrowth of hair taking place within three months. More than 1,500 children have been cured at the Vanderbilt Clinic by this method, without unfavorable results.

Angiomas, formerly treated by surgical methods, injections of hot water, cautery, electrolysis and the like, often necessitating the administration of repeated narcoses and frequently resulting in disfiguring scars, will respond to radium therapy with an outcome that seems magical in the excellence of its surgical and cosmetic results. Many types of angioma of the skin and mucosa which the surgeon of former days did not consider in the light of a possible surgical risk are today readily curable with radium. I wish the same could be said of the port wine mark, but thus far our efforts with the Kromayer lamp and with radium have met with only partly favorable results; I have seen only one cure. In the eradication of pigmented moles, especially the large, ugly looking elevated growths, no old method of treatment can begin to be compared with the freezing method with carbon dioxide snow, devised by William Allen Pusey. In many cases of the chronic, fixed type of lupus erythematosus, refrigeration often seems to be about the only agent capable of producing lasting results.

The treatment of cutaneous tuberculosis and of lupus erythematosus with injections of various gold compounds has aroused great interest among dermatologists. A preliminary report, together with a review of the European literature dealing with this subject, was recently published in the *Archives of Dermatology and Syphilology*, by Jay F. Schamberg and his associates. It is as yet too soon to speak of definite progress, but there is no question in the minds of those who have investigated the matter that the outlook for the near future is a very promising one. Some of our Viennese colleagues have reported very favorably on the use of a new tuberculin ointment in lupus vulgaris.

In the last few years, long strides have been made in the treatment of leprosy with the ethyl esters of chaulmoogra oil. In patients presenting early and relatively benign lesions we are beginning to look forward toward actual cures; I have at present four patients under observation, in whom extensive and deep-seated leprous infiltrations vanished completely under this treatment We are not as yet prepared to say, however, that long-standing and advanced cases of the disease are curable, in the strict sense of the word.

It seems to me that the older we get and the more patients we see, the less certain do we become in our diagnoses, and this applies especially to pemphigus. Only the other day I heard one of our older colleagues, a man practicing thirty-five years, say that he did not see much difference between some cases of pemphigus and some cases of Duhring's disease. To me, that statement seems a bit strong. I concede that it is at times difficult to differentiate the two diseases during a more or less hectic demonstration at a medical meeting; but to one who has such a patient under observation for several weeks, the true state of affairs ought to become manifest without difficulty. Distinct progress has been made in the last several years, in the treatment of certain types of pemphigus. Robert H. and William D. Davis have succeeded in curing a small number of cases with their intravenous iron cacodylate and subcutaneous coagulen injections; the late Grover W. Wende, employing their methods, has also reported very favorably. Good results have been reported by some, indifferent and poor results by others. What is the probable explanation for this variability of response to the same form of treatment? I think the explanation lies in the fact that not all the cases regarded as pemphigus are really pemphigus. Acute, bullous, septic pemphigus, a not uncommon disease in any large city with a proportionately high foreign-born population, is not, in my experience, amenable to any form of treatment; the disease is rapidly fatal. Subacute bullous pemphigus and pemphigus vulgaris occasionally respond to heroic doses of sustained arsenic medication; in pemphigus vegetans and pemphigus foliaceus we often observe periods of remission and exacerbation, the patients dying usually of exhaustion or some intercurrent infection. In speaking of these different clinical varieties, I realize that occasionally one might encounter two or three types of eruption in the same case.

Intravenous injections of quinine and of sodium bicarbonate solutions have, in the hands of some observers, produced promising results. In one respect, we have been lax in the management of these pitiful patients; I refer to our lack of Hebra's permanent bath, used so successfully in the European hospitals for the alleviation of the often intolerable pain and discomfort that characterize the bullous form of the disease. To sum up the situation, I think it can be truthfully said that the outlook is much better today than it was five years ago, and that the next few years will prove fruitful in our efforts to combat the different varieties of pemphigus.

That a knowledge of chemistry is of great value to the dermatotherapist of today is well exemplified by the work done by Udo Wile and his co-workers in the treatment of cutaneous and mental bromism, and by McBride and Dennie in their utilization of Ravaut's method of combating metallic poisoning. In connection with purely medicinal therapy, I cannot refrain from mentioning the case of a remarkable patient presented on several occasions before the New York Dermatological Society, a couple of years ago, by H. H. Whitehouse and Howard Fox. This patient was later also observed by Bedford Shelmire in Riehl's clinic in Vienna. The patient was a young man who presented a universally infiltrated and deeply pigmented skin; we were unable to make a clinical diagnosis, and microscopic study of a piece of his skin did not clarify the situation. The man went to Riehl's clinic, where another section was examined, resulting in the diagnosis of universal xanthomatosis of the skin. Injections of iodipin were administered, and the patient was cured.

It is difficult to resist the temptation to go on with the recitation of the many cutaneous conditions in which advances and improvements in treatment have been made in recent years. Time and space being valuable, permit me to mention only briefly the following illustrative examples: Hyperhidrosis and seborrhea oleosa, two very stubborn disturbances of glandular secretion and excretion, are amenable to roentgen-ray therapy. Keloids, in former days best left severely alone, may now be cured with roentgen rays and radium. The treatment of leukoplakia with electrodesiccation has proved to be quite successful, as William L. Clark demonstrated several years ago. Antimony and potassium tartrate injections are curative in granuloma inguinale. Intravenous injections of typhoid bacilli suspensions will cure large-spored ringworm infections of the beard, and of the scalp, as only recently demonstrated by Martin F. Engman. The persistent disseminate lesions of urticaria pigmentosa have, in a few reported instances, cleared up under roentgen-ray therapy, although we are not yet prepared to speak of cures. The widespread vascular lesions of angioma serpiginosum may be eradicated with the ultraviolet ray. The management of ivy poisoning described by Albert Strickler has been successful in the hands of numerous observers. Pilocarpine injections are occasionally of value in some types of parapsoriasis.

These miscellaneous citations serve to indicate the trend of modern dermatotherapy. They serve also to emphasize the obvious fact that the empiricism that in former years characterized the treatment of skin diseases has in a large measure given place to established scientific procedures, based on a much broader knowledge of medicine as a whole. I think it was Walter Highman who once said, "The dermatologist is an internist who knows the skin." What constitutes the real progress in the treatment of skin diseases today is the wide adaptation of the principles of general medicine to cutaneous pathologic changes. The constitution of the patient, his environment, the rôle played by focal infection, the blood chemistry, the problems of sensitization—these and many other factors are bound to play their important parts in this broad field of medicine.

That we are still only on the threshold of a vast unexplored domain, none of us will attempt to gainsay; but "confession is good for the soul"; and, as the German saying goes, aller Anfang ist schwer. Let us therefore console ourselves with the thought that the near future will be enriched by many a scientific contribution to dermatotherapy and that each contributor may profitably borrow a leaf from the books of our medical committees and "report progress."

24 West Fifty-Ninth Street.

ERYSIPELAS

V. OBSERVATIONS ON THE ETIOLOGY AND TREATMENT WITH ERYSIPELAS ANTISTREPTOCOCCIC SERUM [*]

KONRAD E. BIRKHAUG, M.D.
ROCHESTER, N. Y.

Accumulated evidence pointing to the existence of a specific type of *Streptococcus hemolyticus* as the etiologic agent in erysipelas suggested that a serum made with this specific organism would be beneficial in the treatment of erysipelas. During the last year, an antiserum against this type of streptococcus has been produced and has been used in the treatment of cases of erysipelas. The results of the use of this serum are described in this paper.

The etiology of erysipelas was first studied by Fehleisen,[1] in 1883, and since that time active investigations have been conducted on the biology of *Streptococcus hemolyticus,* particularly by means of serologic methods. Type specificity within the large group of hemolytic streptococci has been a subject of intense study during the last thirty years. As a result of such studies, the causation of scarlet fever appears to have been definitely settled, and measures have subsequently developed for the prevention and cure of that disease. The work on opsonins by Ruediger,[2] Schorer,[3] Tunnicliff,[4] and Boughton,[5] and an important study of agglutination by Tunnicliff [4] suggested that a specific group of hemolytic streptococci was the etiologic agent causing erysipelas. Comprehensive investigations of Dochez, Avery and Lancefield [6] on the biology of the hemolytic streptococci with particular emphasis on agglutination and protection, strongly suggested that cultures of streptococci isolated from cellulitis, erysipelas, scarlet fever and septicemia differed among themselves antigenically, and possibly fell into individual groups. Recently, I [7] was able to demonstrate by means of agglutination and absorption that 91.2 per cent of erysipelas strains of hemolytic streptococci, isolated carefully from typical erysipelatous lesions, fell antigenically into one group, and that this group of streptococci could be readily differentiated by the same methods from strains of hemolytic streptococci isolated from scarlet fever, cellulitis, empyema, peritonitis, sinusitis, puerperal sepsis, tonsillitis and a number of other streptococcic infections.

By means of local passive immunity, Rivers and Tillett[8] successfully demonstrated that small areas of skin infiltrated with an immune monovalent streptococcic serum produced local protection against the culture of hemolytic streptococcus employed for the production of the serum, and that normal serum or beef infusion broth offered little or no protection against the injurious activity of the injected hemolytic streptococci. These authors concluded that the local passive immunity conferred by the immune serum naturally suggested the possible treatment of erysipelas by infiltrating the healthy tissues in the immediate vicinity of the erysipelatous margin with immune serum, on the assumption that when the infection spread to the prepared zone it would meet refractory tissues and be unable to progress farther. These studies I[9] extended in order to determine possible antigenic relationships between erysipelatous and nonerysipelatous strains of hemolytic streptococci. It was demonstrated, by means of intradermal infiltration of the skin of susceptible rabbits with immune erysipelas serum, twenty-four hours previous to the injection of hemolytic streptococci of erysipelas and nonerysipelas origin, that the erysipelas serum offered adequate protection against 93 per cent of cultures of erysipelatous streptococci, and that almost no protection was offered by the erysipelas serum against the injurious action of nonerysipelatous hemolytic streptococci.

In subsequent studies on the experimental production of erysipelas in rabbits, I[10] was able to demonstrate that intracutaneous inoculation of hemolytic streptococci isolated from human cases of erysipelas produced typical erysipelas-like lesions in the skin of normal and susceptible rabbits. The pathologic picture of the erythematous and diffuse lesions produced was strikingly similar in nature to that seen in human cases of erysipelas. Again, it was found that intracutaneous infiltration of mixtures of immune erysipelas serum and hemolytic streptococci of erysipelas origin afforded local protection against the injurious action of the streptococci, and that normal rabbit serum or immune erysipelas serum heated at 60 C. for thirty minutes failed to protect the skin against the harmful effects of the inoculated erysipelatous streptococci. Further, it was demonstrated that intravenous or subcutaneous administration of large doses of immune erysipelas serum protected the animal against lethal doses of hemolytic streptococci isolated from erysipelas, when the serum was injected twenty-four hours before the bacterial inoculation. Normal rabbit serum or immune erysipelas serum heated at 60 C. for thirty minutes offered no protection against the lethal dose of erysipelatous streptococci. No local or general protection was offered by the immune erysipelas serum against the harmful action of hemolytic streptococci isolated from nonerysipelas sources, except in instances of irregular interagglutination of nonerysipelas streptococci with the immune erysipelas serum. At that time it was found that intradermal, intravenous and intramuscular injections of large doses of erysipelas serum offered distinct promise for the specific treatment of the disease in man.

In the study of toxin production of *Streptococcus erysipelatis*, I[11] found that a skin test dose of 0.1 cc. of a 1:1,000 dilution of erysipelas toxic filtrate produced in the skin of susceptible persons a lesion similar to that observed in the Schick and Dick tests. Complete neutralization of such a lesion was obtained by mixing the skin test dose with an equal amount of convalescent erysipelas serum, or 0.001 cc. of erysipelas antistreptococcic rabbit or donkey serums. It was also demonstrated that during the acute stages of erysipelas the patient's blood serum and urine contained a toxic substance, similar in nature to the toxic filtrate produced by *Streptococcus erysipelatis*, which was completely neutralized by convalescent erysipelas serum and which disappeared from the patient's blood serum or urine as soon as from twelve to thirty-six hours after the intramuscular administration of from 25 to 100 cc. of erysipelas antistreptococcic rabbit or donkey serums. Aided by these demonstrations of specific relationship between *Streptococcus erysipelatis* and erysipelas. I was led to believe that the production of a highly antitoxic and possibly bactericidal serum would accomplish curative results.

SPECIFIC TREATMENT OF ERYSIPELAS WITH ANTISTREPTOCOCCIC SERUM

The first curative antistreptococcic serum was made by Charrin and Roger,[12] in 1895. Cultures of streptococci isolated from erysipelas were grown in bouillon for ten days. At the end of incubation, the bouillon was concentrated by evaporation to one tenth of its original volume, placed in the autoclave and exposed to 115 C. In this manner, the authors believed they had preserved the original bacterial substance and its toxic products. This substance was injected intravenously in a mule, the average dose being 30 cc., injected every other day, until a total of 240 cc. of the concentrated, or 2,400 cc. of the original volume, was injected. Fifteen days after the last injection, the mule was bled. A patient severly ill with puerperal septicemia, without peritoneal localization, was injected subcutaneously on three successive days with a total of 41 cc. of the serum. A marked clinical improvement followed the third injection, and on the fourth day the temperature became normal. In rapid succession followed the production of antistreptococcic serums by Marmorek,[13] Aronson,[14] Moser,[15] Savchenko[16] and numerous other investigators, and clinical results were compiled of distinct therapeutic importance, particularly in the treatment of scarlet fever. More recently, attempts have been made by Lavender[17] and Goresco and Popesco[18] to treat erysipelas with antistreptococcic serum; and the results obtained, particularly by Goresco and Popesco, were quite striking in the amelioration of the patiens's toxic depression, even when the temperature remained elevated.

Having confirmed the work of other investigators and having demonstrated more extensively the existence of a specific type of *Streptococcus hemolyticus* as the etiologic agent in erysipelas, I proceeded, in the fall of 1924, to immunize a donkey and later a horse against *Streptococcus erysipelatis*. The method of immunization was that suggested by Dochez[19] for the production of scarlatinal antistreptococcic serum. Through the kindness of Dr. Dochez, who permitted the use of his method of immunization for experimental purposes and through the interest and cooperation of Dr. G. W. Goler, health officer of Rochester, and local physicians, we have been able to submit the erysipelas antistreptococcic serum to clinical trial in a limited number of cases.

The results obtained strongly suggested that the serum possessed therapeutic value when administered in the early stages of the disease and in adequate doses.

THERAPEUTIC RECORDS

Sixty patients have been treated specifically up to the present time. All of the severe cases presented hyperpyrexia, tachycarida, moderate toxemia, and widespread erysipelatous lesions on the face, neck and scalp, accompanied by marked edema and severe tenderness in the affected areas. Two patients were moribund when first visited; twenty were considered severely ill; thirty-one were moderately ill, and seven mildly ill. Fifteen patients were treated on the second day of the disease, eighteen on the third day, twelve on the fourth and fifth days, respectively, two on the sixth, and one on the eighth day of the disease. The average dose of serum administered intramuscularly was 100 cc. of the unconcentrated lot, and 15 cc. of the concentrated globulin serum. In only eight cases was more than one dose administered. In every case, a sensitization skin test was performed with the serum, previous to the injection of the therapeutic dose.

The dominant clinical effect of the specific serum therapy in erysipelas was the prompt inprovement of the toxic depression of the patient; this was followed by a rapid and almost critical drop in the temperature, pulse and respiratory rate, observed as soon as from twelve to eighteen hours following the injection of the serum. The most striking clinical effect noted in the patients treated during the early stages of the disease was the rapid disappearance and fading of the erysipelatous lesion and the absorption of the blebs and pitting edema in the previously affected parts. Although it was observed in the late stages of the disease that the temperature and pulse yielded by lysis to the serum therapy, the amelioration of toxic depression was quite distinct within from twelve to eighteen hours after the injection of the serum.

Of the sixty patients treated, twelve brief case reports follow:

REPORT OF CASES

Case 1.—I. M., a woman, aged 39, admitted to the Rochester Municipal Hospital, a patient of Dr. P. A. Bly, Oct. 24, 1925, about eighty hours after the appearance of a sharply defined patch of redness across the bridge of the nose, was extremely toxic and prostrated; the erysipelatous lesion extended over the entire face, except the upper lip; both eyelids were greatly swollen; the conjunctivae were red and watery; both the ears were swollen and shiny, and extremely tender to touch; the margin of the lesion was markedly raised, palpable and irregular in outline, extending above to the hair-line and below to the angle of the jaw, where it abruptly stopped; there was pitting edema of the neck; the cervical and submaxillary glands were markedly enlarged. The temperature was 104.4; the pulse, 116 and respiration, 22.

October 24, at 5 p. m., 40 cc. of erysipelas antistreptococcic serum was injected intramuscularly, and two skin test doses of erysipelas streptococcic toxin were injected intradermally (chart 1).

October 25, at 8 a. m., the temperature was 100.8; the pulse 96 and respiration, 16. The patient's general condition was markedly improved; she did not appear toxic and was well oriented; the erysipelatous lesion was pale; no extension of the margins was noted. The skin test doses of the erysipelas streptococcic toxin had caused a positive reddening at the site of injection, which measured 3 cm. in diameter. At 8 p. m., the temperature suddenly rose to 104 and the pulse to 116. The patient complained of intense headache and nausea; the erysipelatous lesion assumed a deep red, and edema of the forehead caused her a great deal of pain. At 8:15 p. m., 40 cc. of erysipelas antistreptococcic serum was injected intramuscularly. The patient spent a restful night.

October 26, at 8 a. m., the temperature was 100.3; the pulse, 94 and respiration, 14. The general condition was markedly improved; edema of the forehead was completely gone; she was able to open both eyes, and the redness of the conjunctivae had cleared up. The skin was still deeply red and hot; the skin test dose of toxin was definitely positive. At 4 p. m., 50 cc. of erysipelas antistreptococcic serum was injected intramuscularly. At 12 p. m., the temperature reached 99.1; the pulse, 86 and respiration, 14. The lesion was rapidly fading, and a marked clinical improvement had occurred in the general condition.

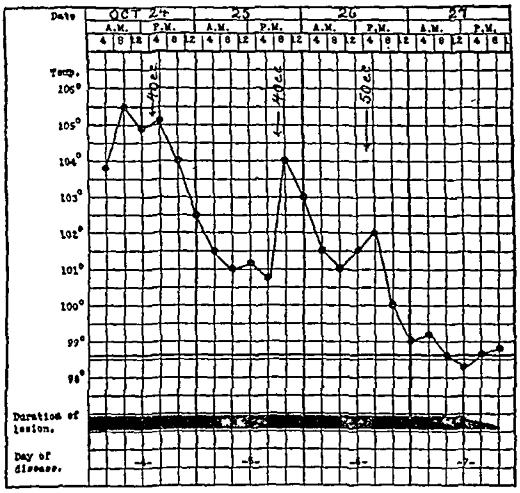

Chart 1.—Temperature course in patient 1, admitted on the fourth day after the onset of erysipelas.

October 27, at 8 a. m., the temperature was 98.7, the pulse, 86 and respiration, 14. The face looked pale and scaly; the edema of the face, scalp and neck had completely disappeared; the cervical and submaxillary glands were greatly reduced in size and not tender. The patient felt comfortable.

Aside from the development of a left otitis media, November 1, the patient has remained well.

Case 2.—C. L., a woman, aged 55, a private patient of Dr. J. Carlucci, Nov. 7, 1925, was taken suddenly ill with nausea, chills, frequent vomiting and profuse perspiration. The following morning she noticed a small patch of redness on the right side of the nose, which during the day rapidly spread across the right side of the face, involving the right eyelids and ear. The patient was moderately prostrated toward evening and sustained two fainting attacks. Novemer 9, the lesion had progressively spread to the scalp and over the left side of the face; edema of the eyelids completely closed the eyes. November 10, at 9 p. m., the temperature was 106.2; the pulse, 146 and respiration, 28. Convulsions occurred, and the patient remained delirious during the night.

November 11, the fifth day of the disease, at 2:15 p. m., the lesion had extended to the supraclavicular fossa; the entire tination and absorption that 91.2 per cent of erysipelas strains of hemolytic streptococci, isolated carefully from typical erysipelatous lesions, fell antigenically into one group, and that this group of streptococci could be readily differentiated by the same methods from strains of hemolytic streptococci isolated from scarlet fever, cellulitis, empyema, peritonitis, sinusitis, puerperal sepsis, tonsillitis and a number of other streptococcic infections.

[19] Dochez, A. R.: Significance of Streptococcus Hemolyticus in Scarlet Fever, J. A. M. A. 82:542 (Feb. 16) 1924.

By means of local passive immunity, Rivers and Tillett[8] successfully demonstrated that small areas of skin infiltrated with an immune monovalent streptococcic serum produced local protection against the culture of hemolytic streptococcus employed for the production of the serum, and that normal serum or beef infusion broth offered little or no protection against the injurious activity of the injected hemolytic streptococci. These authors concluded that the local passive immunity conferred by the immune serum naturally suggested the possible treatment of erysipelas by infiltrating the healthy tissues in the immediate vicinity of the erysipelatous margin with immune serum, on the assumption that when the infection spread to the prepared zone it would meet refractory tissues and be unable to progress farther. These studies I[9] extended in order to determine possible antigenic relationships between erysipelatous and nonerysipelatous strains of hemolytic streptococci. It was demonstrated, by means of intradermal infiltration of the skin of susceptible rabbits with immune erysipelas serum, twenty-four hours previous to the injection of hemolytic streptococci of erysipelas and nonerysipelas origin, that the erysipelas serum offered adequate protection against 93 per cent of cultures of erysipelatous streptococci, and that almost no protection was offered by the erysipelas serum against the injurious action of nonerysipelatous hemolytic streptococci.

In subsequent studies on the experimental production of erysipelas in rabbits, I[10] was able to demonstrate that intracutaneous inoculation of hemolytic streptococci isolated from human cases of erysipelas produced typical erysipelas-like lesions in the skin of normal and susceptible rabbits. The pathologic picture of the erythematous and diffuse lesions produced was strikingly similar in nature to that seen in human cases of erysipelas. Again, it was found that intracutaneous infiltration of mixtures of immune erysipelas serum and hemolytic streptococci of erysipelas origin afforded local protection against the injurious action of the streptococci, and that normal rabbit serum or immune erysipelas serum heated at 60 C. for thirty minutes failed to protect the skin against the harmful effects of the inoculated erysipelatous streptococci. Further, it was demonstrated that intravenous or subcutaneous administration of large doses of immune erysipelas serum protected the animal against lethal doses of hemolytic streptococci isolated from erysipelas, when the serum was injected twenty-four hours before the bacterial inoculation. Normal rabbit serum or immune erysipelas serum heated at 60 C. for thirty minutes offered no protection against the lethal dose of erysipelatous streptococci. No local or general protection was offered by the immune erysipelas serum against the harmful action of hemolytic streptococci isolated from nonerysipelas sources, except in instances of irregular interagglutination of nonerysipelas streptococci with the immune erysipelas serum. At that time it was found that intradermal, intravenous and intramuscular injections of large doses of erysipelas serum offered distinct promise for the specific treatment of the disease in man.

In the study of toxin production of *Streptococcus erysipelatis*, I[11] found that a skin test dose of 0.1 cc. of a 1:1,000 dilution of erysipelas toxic filtrate produced in the skin of susceptible persons a lesion similar to that observed in the Schick and Dick tests. Complete neutralization of such a lesion was obtained by mixing the skin test dose with an equal amount of convalescent erysipelas serum, or 0.001 cc. of erysipelas antistreptococcic rabbit or donkey serums. It was also demonstrated that during the acute stages of erysipelas the patient's blood serum and urine contained a toxic substance, similar in nature to the toxic filtrate produced by *Streptococcus erysipelatis*, which was completely neutralized by convalescent erysipelas serum and which disappeared from the patient's blood serum or urine as soon as from twelve to thirty-six hours after the intramuscular administration of from 25 to 100 cc. of erysipelas antistreptococcic rabbit or donkey serums. Aided by these demonstrations of specific relationship between *Streptococcus erysipelatis* and erysipelas, I was led to believe that the production of a highly antitoxic and possibly bactericidal serum would accomplish curative results.

SPECIFIC TREATMENT OF ERYSIPELAS WITH ANTISTREPTOCOCCIC SERUM

The first curative antistreptococcic serum was made by Charrin and Roger,[12] in 1895. Cultures of streptococci isolated from erysipelas were grown in bouillon for ten days. At the end of incubation, the bouillon was concentrated by evaporation to one tenth of its original volume, placed in the autoclave and exposed to 115 C. In this manner, the authors believed they had preserved the original bacterial substance and its toxic products. This substance was injected intravenously in a mule, the average dose being 30 cc., injected every other day, until a total of 240 cc. of the concentrated, or 2,400 cc. of the original volume, was injected. Fifteen days after the last injection, the mule was bled. A patient severly ill with puerperal septicemia, without peritoneal localization, was injected subcutaneously on three successive days with a total of 41 cc. of the serum. A marked clinical improvement followed the third injection, and on the fourth day the temperature became normal. In rapid succession followed the production of antistreptococcic serums by Marmorek,[13] Aronson,[14] Moser,[15] Savchenko[16] and numerous other investigators, and clinical results were compiled of distinct therapeutic importance, particularly in the treatment of scarlet fever. More recently, attempts have been made by Lavender[17] and Goresco and Popesco[18] to treat erysipelas with antistreptococcic serum; and the results obtained, particularly by Goresco and Popesco, were quite striking in the amelioration of the patiens's toxic depression, even when the temperature remained elevated.

Having confirmed the work of other investigators and having demonstrated more extensively the existence of a specific type of *Streptococcus hemolyticus* as the etiologic agent in erysipelas, I proceeded, in the fall of 1924, to immunize a donkey and later a horse against *Streptococcus erysipelatis*. The method of immunization was that suggested by Dochez[19] for the production of scarlatinal antistreptococcic serum. Through the kindness of Dr. Dochez, who permitted the use of his method of immunization for experimental purposes and through the interest and cooperation of Dr. G. W. Goler, health officer of Rochester, and local physicians, we have been able to submit the erysipelas antistreptococcic serum to clinical trial in a limited number of cases.

The results obtained strongly suggested that the serum possessed therapeutic value when administered in the early stages of the disease and in adequate doses.

THERAPEUTIC RECORDS

Sixty patients have been treated specifically up to the present time. All of the severe cases presented hyperpyrexia, tachycarida, moderate toxemia, and widespread erysipelatous lesions on the face, neck and scalp, accompanied by marked edema and severe tenderness in the affected areas. Two patients were moribund when first visited; twenty were considered severely ill; thirty-one were moderately ill, and seven mildly ill. Fifteen patients were treated on the second day of the disease, eighteen on the third day, twelve on the fourth and fifth days, respectively, two on the sixth, and one on the eighth day of the disease. The average dose of serum administered intramuscularly was 100 cc. of the unconcentrated lot, and 15 cc. of the concentrated globulin serum. In only eight cases was more than one dose administered. In every case, a sensitization skin test was performed with the serum, previous to the injection of the therapeutic dose.

The dominant clinical effect of the specific serum therapy in erysipelas was the prompt improvement of the toxic depression of the patient; this was followed by a rapid and almost critical drop in the temperature, pulse and respiratory rate, observed as soon as from twelve to eighteen hours following the injection of the serum. The most striking clinical effect noted in the patients treated during the early stages of the disease was the rapid disappearance and fading of the erysipelatous lesion and the absorption of the blebs and pitting edema in the previously affected parts. Although it was observed in the late stages of the disease that the temperature and pulse yielded by lysis to the serum therapy, the amelioration of toxic depression was quite distinct within from twelve to eighteen hours after the injection of the serum.

Of the sixty patients treated, twelve brief case reports follow:

REPORT OF CASES

Case 1.—I. M., a woman, aged 39, admitted to the Rochester Municipal Hospital, a patient of Dr. P. A. Bly, Oct. 24, 1925, about eighty hours after the appearance of a sharply defined patch of redness across the bridge of the nose, was extremely toxic and prostrated; the erysipelatous lesion extended over the entire face, except the upper lip; both eyelids were greatly swollen; the conjunctivae were red and watery; both the ears were swollen and shiny, and extremely tender to touch; the margin of the lesion was markedly raised, palpable and irregular in outline, extending above to the hair-line and below to the angle of the jaw, where it abruptly stopped; there was pitting edema of the neck; the cervical and submaxillary glands were markedly enlarged. The temperature was 104.4; the pulse, 116 and respiration, 22.

October 24, at 5 p. m., 40 cc. of erysipelas antistreptococcic serum was injected intramuscularly, and two skin test doses of erysipelas streptococcic toxin were injected intradermally (chart 1).

October 25, at 8 a. m., the temperature was 100.8; the pulse 96 and respiration, 16. The patient's general condition was markedly improved; she did not appear toxic and was well oriented; the erysipelatous lesion was pale; no extension of the margins was noted. The skin test doses of the erysipelas streptococcic toxin had caused a positive reddening at the site of injection, which measured 3 cm. in diameter. At 8 p. m., the temperature suddenly rose to 104 and the pulse to 116. The patient complained of intense headache and nausea; the erysipelatous lesion assumed a deep red, and edema of the forehead caused her a great deal of pain. At 8:15 p. m., 40 cc. of erysipelas antistreptococcic serum was injected intramuscularly. The patient spent a restful night.

October 26, at 8 a. m., the temperature was 100.3; the pulse, 94 and respiration, 14. The general condition was markedly improved; edema of the forehead was completely gone; she was able to open both eyes, and the redness of the conjunctivae had cleared up. The skin was still deeply red and hot; the skin test dose of toxin was definitely positive. At 4 p. m., 50 cc. of erysipelas antistreptococcic serum was injected intramuscularly. At 12 p. m., the temperature reached 99.1; the pulse, 86 and respiration, 14. The lesion was rapidly fading, and a marked clinical improvement had occurred in the general condition.

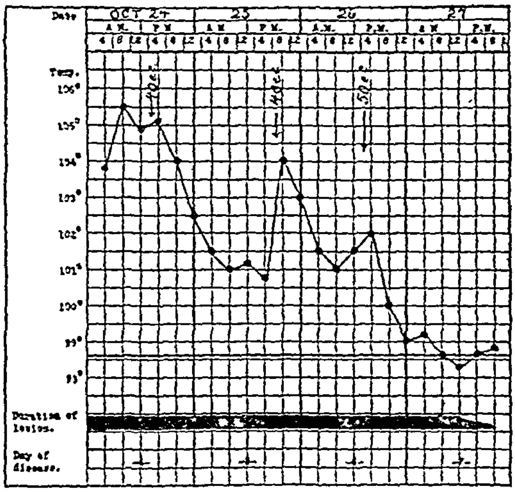

Chart 1.—Temperature course in patient 1, admitted on the fourth day after the onset of erysipelas.

October 27, at 8 a. m., the temperature was 98.7, the pulse, 86 and respiration, 14. The face looked pale and scaly; the edema of the face, scalp and neck had completely disappeared; the cervical and submaxillary glands were greatly reduced in size and not tender. The patient felt comfortable.

Aside from the development of a left otitis media, November 1, the patient has remained well.

Case 2.—C. L., a woman, aged 55, a private patient of Dr. J. Carlucci, Nov. 7, 1925, was taken suddenly ill with nausea, chills, frequent vomiting and profuse perspiration. The following morning she noticed a small patch of redness on the right side of the nose, which during the day rapidly spread across the right side of the face, involving the right eyelids and ear. The patient was moderately prostrated toward evening and sustained two fainting attacks. Novemer 9, the lesion had progressively spread to the scalp and over the left side of the face; edema of the eyelids completely closed the eyes. November 10, at 9 p. m., the temperature was 106.2; the pulse, 146 and respiration, 28. Convulsions occurred, and the patient remained delirious during the night.

November 11, the fifth day of the disease, at 2:15 p. m., the lesion had extended to the supraclavicular fossa; the entire

face and neck were purplish red; the skin was hot, swollen and shiny; several large blebs had formed on the face and the ears; the patient was delirious. The temperature was 104.6; the pulse, 148 and respiration, 28. At 2:30 p. m., 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses of toxin were injected intradermally. At 12 p. m., the temperature was 101.4; the pulse, 110 and respiration, 18. There was no extension of the erysipelatous margin, and the patient was sleeping quietly (chart 2).

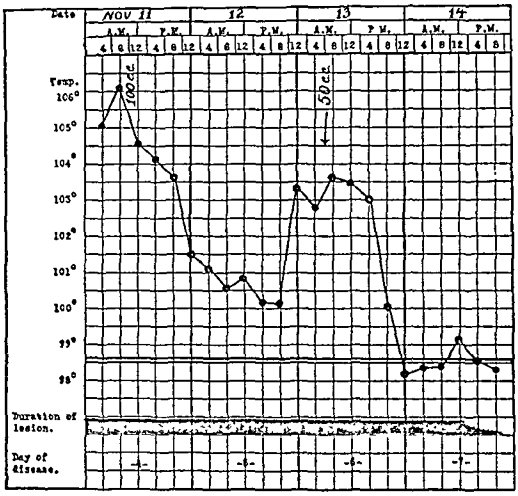

Chart 2.—Temperature course in patient 2, admitted on the fifth day after the onset of erysipelas.

November 12, at 12 a. m., there was a distinct clinical improvement in the patient's general condition; she did not appear toxic; she was able to open both eyes, and the pitting edema of the face and neck had completely disappeared; the erysipelatous lesion seemed paler, and there was no fresh extension. The skin test dose of toxin was strongly positive, the redness measuring 3.6 cm. in diameter. At 12 p. m., the patient had a chill, vomited, and perspired freely for several hours. The temperature rose to 103.4; the pulse to 124 and respiration to 24. There was a recurrence of the swelling of the face and neck.

November 13, at 8 a. m., the temperature was 103.6; the pulse, 120 and respiration, 24. The patient appeared very toxic and drowsy; the erysipelatous lesion had not extended beyond the margins previously established. At 8:10 a. m., 50 cc. of erysipelas serum was injected intramuscularly. At 8 p. m., the temperature was 100; the pulse, 94 and respiration, 16. A striking reduction in the color of the erysipelatous lesion was noticed, and an almost complete absorption of the pitting edema of the face and the neck; the patient was clearly oriented and expressed herself greatly relieved of the previously depressing headache and facial tenderness. At 12 p. m., the temperature was 98.2; the pulse, 96 and respiration, 16. The face appeared pale, and the blebs were almost completely desiccated.

November 14, at 8 a. m., the temperature was 98.4; the pulse, 90 and respiration 14. The patient was talkative and comfortable; the facial lesions had almost completely disappeared, leaving the skin very dry and cracked; only a small red spot was noted on the left ear. The cervical and submaxillary glands were still large and tender. The skin test of toxin was negative.

November 15, the temperature, pulse and respiration were normal; the patient was found sitting up in bed; fine desquamations covered the entire face; the throat was less painful. Except for an attack of serum urticaria, November 21, she has remained well without developing complications.

Case 3.—J. R., a woman, aged 58, a private patient of Dr. H. A. Sadden, Nov. 15, 1925, experienced painful sensations in the tip of the right ear; she scratched the ear until it became abraded. About ten hours later the ear became greatly swollen, red, hot, tense, with a raised palpable margin that rapidly progressed toward the angle of the jaw and the bridge of the nose. The patient became nauseated and vomited once during the evening. November 16, the spreading red edge had extended over the entire right side of the face and 2 cm. beyond the hair-line; face and features were greatly swollen, and the right eyelids were tense, enlarged and completely closed the eye; the neck was slightly swollen, and the right submaxillary glands were enlarged; three large blebs developed over the right cheek bone; the patient was greatly distressed. The temperature was 102; the pulse, 128 and respiration, 22.

November 16, on the second day of the disease, at 5:30 p. m., 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses of toxin intradermally.

November 17, at 8 a. m., marked clinical improvement had occurred; the temperature was 98.1; the pulse, 84 and respiration, 16; the erysipelatous lesion had completely disappeared, leaving the skin dry and cracking at the sites of the desiccated blebs; the skin of the face was pale; the right eyelids appeared normal in size and fulness; the skin test dose of toxin was negative. The patient was feeling comfortable, except for a slight headache.

November 18, the temperature, pulse and respiration were normal and the general condition was satisfactory; the face appeared normal, but for desquamation. The patient has remained well, and no complications have developed.

Case 4.—O. R., a man, aged 41, a private patient of Dr. R. S. Wilcox, seen on the morning of Nov. 16, 1925, complained of chilliness, headache, backache, and general weakness. The temperature was 101.6; the pulse 90 and respiration, 24. Physical examination was negative except for a slight coryza and a suspicious redness over the left side of the nose.

November 17, at 12 a. m., the temperature was 102.4; the pulse, 100 and respiration, 24. There were marked redness of the skin of the left side of the face, nose, ear, and left side of the forehead, considerable edema and many small blebs.

November 18, at 11 a. m., the temperature was 103; the pulse, 110 and respiration, 24. Both sides of the face, neck and forehead were markedly red and edematous; the left eye was practically closed; there was a very large bleb on the left ear. At 5 p. m., the temperature was 103.6; the pulse 110 and respiration, 34. The patient was quite prostrated. At 5:30 p. m., 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses of toxin intradermally (chart 3).

November 19, at 9:30 a. m., a remarkable change was noted in the general condition; the swelling of the head, face and neck was greatly reduced; the redness of the skin was rapidly fading and the blebs on the ears were smaller. The temperature was 99.2; the pulse, 90 and respiration, 20. The patient felt much better and was comfortable. The skin test dose of toxin was negative.

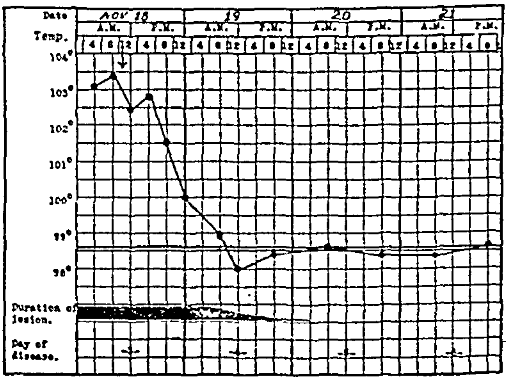

Chart 3.—Temperature course in patient 4, admitted on the third day after the onset of erysipelas. Arrow indicates injection of 100 cc. of serum.

November 20, at 9 a. m., the temperature was 98.6; the pulse, 84 and respiration, 18. The swelling of the face had practically disappeared; the redness was almost faded and the blebs gone.

November 21, the temperature, pulse and respiration were normal. There was no swelling on the face; the redness of the skin was completely gone; the skin was somewhat scaly.

The patient remained normal in every way until November 26, when serum sickness appeared. From November 29, he had an uneventful convalescence.

Case 5.—R. B., a man, aged 28, a private patient of Dr. I. Messinger, had recurrent attacks of erysipelas on the right leg for the last eighteen months, the attacks usually occurring every six weeks, and lasting from eight to ten days, when he was confined to bed with general malaise, rigor and pyrexia.

Nov. 15, 1925, the patient complained of general weakness in the right leg and noticed a red patch, slightly swollen and tender just below the right knee. There was no abrasion of the skin. A definite spreading red edge developed which, after sixteen hours, had circumscribed the entire leg from the hip down to the ankle; there was pitting edema along the entire leg; the skin was deeply purplish red, warm, smooth and tense.

November 16, at 3 p. m., the margin of the erysipelatous lesion had extended to the toes on the right leg; the patient was prostrated and in intense pain. The temperature was 101.6; pulse, 124 and respiration, 18. At 3:20, 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses intradermally.

November 17, at 10 a. m., the temperature was 98.6; the pulse, 84 and respiration, 14. The erysipelatous lesion had completely disappeared from the right leg; only a small area of redness, 3 cm. in diameter, was found across the internal malleolus; there was no edema or tenderness. The general condition was quite satisfactory except for a mild headache. The skin test dose of toxin was negative.

November 18, the temperature, pulse and respiration were normal; the right leg was apparently normal; the patient was able to walk to the bathroom without difficulty. November 20, he returned to work. He remained well, without developing complications, until January 10, when the old lesion recurred on the right leg. The onset of the lesion was gradual, and the patches of redness that developed were confined to a small area above the knee. The attack was unattended by any general symptoms and lasted four days. A repeated intradermal injection of two skin test doses of toxin gave a strongly positive reaction. Active immunization by means of graduated doses of erysipelas streptococcic toxic filtrate is in process.

Case 6.—L. Y., a woman, aged 55, a private patient of Dr. G. H. Gage, had had attacks of recurrent erysipelas for the last two years; the attacks had always been on the lower left leg, usually commencing on the big toe and rapidly spreading toward the knee, circumscribing the entire lower leg; the average duration of these attacks has been ten days, when the patient has been confined to bed with the characteristic symptoms of febrile reaction.

Nov. 23, 1925, she noticed a small area of redness on the dorsum of the left big toe; a definite, spreading, red edge developed, which advanced slowly over the entire dorsum of the foot, involving all the toes; the skin was hot, markedly smooth and tense, and pitting edema with extreme tenderness on pressure was noted in the involved areas; marked prostration followed.

November 25, at 1:30 p. m., the temperature was 101.2; the pulse, 110 and respiration, 20. A dose of 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses of toxin intradermally.

November 26, at 11 a. m., the temperature was 98.4; the pulse, 84 and respiration, 14. The general condition was strikingly improved; swelling of the foot was almost completely gone, and the redness of the erysipelatous lesion rapidly fading; no extension of the lesion was noted; the patient was resting comfortably. The skin test dose of toxin was negative.

November 27, the temperature, pulse and respiration were normal; the redness on the dorsum of the left foot had completely disappeared, leaving the skin dry and scaly; there was no edema or tenderness; the patient's general condition was satisfactory. Except for serum sickness, which occurred, December 8, she has remained well, having developed no complication or recurrent attack of erysipelas.

Case 7.—C. B., a woman, aged 48, a private patient of Drs. T. Jameson and S. H. Gibb, Jan. 1, 1926, complained of general malaise, with pains in the region along the angle of the right lower jaw; the right submaxillary glands were markedly swollen; a definite erysipelatous blush, with raised margins and tense overlying skin, was noticed from the border of the right lower jaw toward the middle of the region of the right parotid gland. The temperature was 102; the pulse, 100 and respiration, 22. The following two days, the margin of the erysipelatous lesion advanced toward the bridge of the nose, involving the entire right side of the face and the right ear; the right eyelids were markedly swollen. An effort to limit the spread of the lesion by means of a ring of contractile collodion failed.

January 4, at 1 p. m., 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly. The temperature at 5 p. m. was 103.6; the pulse, 108 and respiration, 20. At 11 p. m., the patient was resting comfortably; the temperature was 100.8; pulse, 98 and respiration, 18.

January 5, at 8 a. m., the temperature was 99; the pulse, 98 and respiration, 14. The change in the clinical picture was remarkable; the redness was greatly faded over the entire erysipelatous lesion; the local tenderness and the burning sensations had disappeared; the swelling of the submaxillary glands was less intense; over the bridge of the nose was an extension of the reddening, measuring about an inch. Otherwise the patient's general condition was satisfactory.

January 6, at 12 a. m., the temperature was 98.6; the pulse, 86 and respiration, 14, the entire face had cleared up, except for a faint redness over the previously infected areas. The patient was feeling very much better.

January 9, marked urticaria manifested itself. Joint pains were largely controlled by sodium salicylate. The patient has since remained well, without developing complications.

Case 8.—S. M., a woman, aged 38, a private patient of Dr. J. G. Hart, Dec. 14, 1925, was seen in the physician's office complaining of reddening and swelling of the left ear. The margin of the reddening was definitely raised, irregular in outline, extending from the left ear, over the mastoid area and toward the angle of the left jaw. The temperature was 98.4; the pulse, 76 and respiration, 18. The patient was sent home and to bed.

December 15, at 1:30 p. m., the lesion had spread over the left side of the face, involving the left eyelids. The patient was very uncomfortable, complaining of itchiness and tenderness over the entire face. The temperature was 100.4; the pulse, 86 and respiration, 22. The following two days, the general condition became worse, and the lesion continued to spread across the forehead and beyond the hair-line. December 17, the temperature remained elevated all day between 102 and 102.4; the pulse was 110 and respiration, 22. The patient was prostrated.

December 18, at 12:30 p. m., the temperature was 102.1; the pulse, 104 and respiration, 22. The patient was extremely uncomfortable and feverish. The margin of the erysipelatous lesion had extended toward the occipital portion of the neck; the face and forehead were greatly swollen, and the left edematous eyelids completely closed the eye. At 12:45, 50 cc. of erysipelas antistreptococcic serum was injected intramuscularly.

December 19, at 8 a. m., there was noted a clinical change in the patient's general condition. The lesion on the face and forehead had almost completely disappeared, and she was able to open the left eye; the tenderness and edema were gone from the face; a slight swelling was noticed in the occipital region. The temperature was 99.1; the pulse, 84 and respiration, 16. The patient was feeling very much relieved. At 8 p. m., the temperature had dropped to 98.4; the pulse to 76 and the respiration to 14. The face appeared pale and crusted. Tenderness and swelling in the left occipital region were less intense, and the redness was rapidly fading.

December 20, the temperature, pulse and respiration were normal; the general condition was satisfactory. December 25, serum sickness developed. The patient has since remained well; no complications have developed.

Case 9.—G. S., woman, aged 48, a private patient of Dr. M. S. Collier, Jan. 19, 1926, was taken suddenly ill with nausea, chills, frequent vomiting and fever. She noticed a small abrasion on the right side of the nose, surrounded by a large area of deep redness and marked swelling. The following day, the redness and swelling had spread over the entire nose and rapidly assumed the "butterfly pattern" across both cheeks. January 21, the lesion had extended over the entire face, forehead and both ears. The patient was markedly prostrated. The temperature was 103.2; the pulse, 98 and respiration, 26. At 10:30 p. m., she became delirious and convulsive. The margin of the erysipelatous lesion had passed beyond the hair-line; the face was deeply reddish purple; the eyes were completely closed by the marked swelling of the eyelids.

January 22, at 4 p. m., the temperature was 103.4; pulse 100 and respiration, 22. The margin of the erysipelatous lesion had invaded the scalp, some 8 cm. beyond the hair-line; pitting edema was marked over the forehead and scalp; the skin was very tense, hot, shiny and deeply injected. At 4:30, 100 cc. of erysipelas antistreptococcic serum was injected intramuscularly and two skin test doses of toxin intradermally (chart 4).

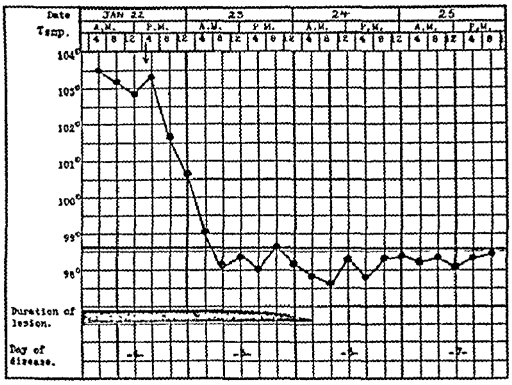

Chart 4.—Temperature course in patient 9, admitted on the fourth day after the onset of erysipelas. Arrow indicates injection of 100 cc. of serum.

January 23, at 9 a. m., the temperature was 98.2; the pulse, 74 and respiration, 14. The puffiness of the face had disappeared, and the intense redness previously noticed was greatly faded over the central portion of the face; the scalp and posterior portion of the neck were still tender, although the pitting edema was almost gone. The patient was clearly oriented and feeling very much better. The injection of the fauces and the submaxillary glandular swelling were less marked. The skin test dose of toxin was negative.

January 24, the temperature, pulse and respiration were normal. The face, neck and scalp were slightly flushed; both eyes were free from any edema; the ears were rapidly restored to their normal size; the throat was less sore, and the submaxillary glands were small and not tender. The patient's general condition was very satisfactory. The convalescence has been uneventful, and no complication has developed.

Case 10.—E. W., a school girl, aged 13, admitted to the Rochester General Hospital, Jan. 22, 1926, was operated on for mastoiditis, January 23, and was doing nicely until, January 26, the edges of the surgical wound became greatly inflamed and suppurative; a well defined red margin rapidly spread across the left side of the face, involving the entire left ear. The following day the lesion had extended to the ramus of the left lower jaw and half-way across the bridge of the nose; the patient was feverish, restless and slightly nauseated. Several large blebs formed on the cheek, and the induration of the skin was firm.

January 27, at 4 p. m., the temperature was 103.2; the pulse, 96 and respiration, 20. At 4:10, 10 cc. of concentrated globulin erysipelas antistreptococcic serum was injected intramuscularly. The patient rested quietly during the night (chart 5).

January 28, at 6 a. m., the temperature had dropped to 99.4 and the pulse was 84. The general condition was satisfactory, and the erysipelatous lesion was less intense in redness; a slight extension of the erysipelatous margin was noted over the bridge of the nose. At 8 p. m., the temperature suddenly rose to 100.6, and the patient complained of pain in the surgical wound; suppuration from the wound was profuse. The blebs on the cheek had completely dried up; the redness of the face was less intense.

January 29, at 8 a. m., the temperature was 98.3; the pulse, 80 and respiration, 20. The patient was comfortable; the erysipelatous lesion had almost completely disappeared from the face; there was no tenderness or edema.

January 30, at 8 a. m., the temperature was 98.2 and the pulse 78; the patient was in excellent condition and was discharged from the hospital.

Case 11.— R. M., a school girl, aged 9 years, a patient of Dr. P. A. Bly, was admitted to the Rochester Municipal Hospital, Nov. 10, 1925, six days after the onset of erysipelas of the right lower leg. There was general prostration. November 11, at 8 p. m., the lesion had progressed to the knee; the temperature was 104.4; the pulse, 136 and respiration, 20. The patient was given 40 cc. of erysipelas antistreptococcic serum intramuscularly. November 12, at 10 a. m., the temperature had fallen to 101.4; the pulse was 108 and respiration, 16. The redness of the lesion was markedly reduced and not extended; the patient was resting comfortably. November 13, the lesion extended to the sole of the foot; there was no extension at the knee. November 14, the entire lesion was markedly blanched with no extension; the temperature was 100 and the pulse, 94. November 15, the temperature and pulse were normal; the general condition was satisfactory; the redness of the leg was rapidly fading. The patient has since remained well, having developed no complications.

Case 12.—F. G., a woman, aged 60, a patient of Dr. P. A. Bly, was admitted to the Rochester Municipal Hospital, Dec. 7, 1925, eight days after the first appearance of erysipelas on the right cheek. The entire face, neck, ears and scalp were involved. There were severe adenitis, general malaise, nausea and vomiting. At 11:40 p. m., the temperature was 104.3; the pulse 86 and respiration, 24. The patient was given 100 cc. of erysipelas antistreptococcic serum intramuscularly. December 8, there was no extension of the erysipelas; the toxic depression was greatly relieved; the temperature at 8 p. m., was 100.4; the pulse, 68 and respiration, 16. The patient was given a second 100 cc. of erysipelas antistreptococcic serum intramuscularly at 9 p. m.; she slept well all night. December 9, the temperature fell to 99.1 and the pulse to 72. There was no extension of the lesion; she felt fairly comfortable; the adenitis was aggravating. The following three days, the patient suffered with severe headaches, sore throat and general lassitude; the lesion had spread slightly along the dependent portions of the neck. December 12, the temperature and pulse became normal; the erysipelatous lesions rapidly disappeared, and the adenitis was markedly relieved. She has since remained well, having had an uneventful convalescence.

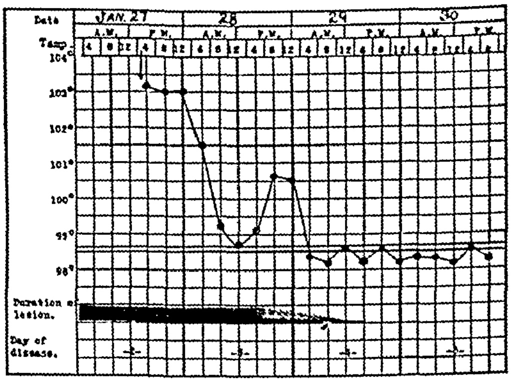

Chart 5.—Temperature course of patient 10, admitted on the second day after the onset of erysipelas. Arrow indicates injection of 10 cc. of serum.

CONCLUSIONS

Further experimental evidence is advanced to prove that the etiologic agent in erysipelas is a specific type of *Streptococcus hemolyticus* and that the serum produced with this specific type of micro-organism possesses very marked curative properties when administered early in the disease.

Clinical trials in sixty moderately severe cases of erysipelas have demonstrated that intramuscular injection of erysipelas antistreptococcic serum, in amounts of 100 cc. of the unconcentrated and from 15 to 20 cc. of the concentrated serum, when administered during the first three days of the disease, causes a prompt amelioration of toxic depression, a critical fall in temperture and pulse rate, prompt fading of the erysipelatous lesion, and rapid absorption of the blebs and edema within the affected areas.

In late cases of erysipelas, the result of serum therapy is strikingly favorable in ameliorating the general toxic depression, although repeated injections of serum may be necessary completely to neutralize the circulating toxin in the patient's blood. Following each injection of the serum, there is noted a critical drop in temperature and pulse to within normal limits as soon as from twelve to eighteen hours after the injection of the serum; the symptoms may quickly return, and a second dose may be necessary to bring about a complete recovery.

By means of a skin test dose of toxin injected intradermally and simultaneously with the intramuscular therapeutic dose, it is possible to observe whether complete neutralization of the circulating toxins is accomplished, or whether an inadequate dose of serum was administered the patient to accomplish the cure of the disease.

It is too early to state whether the serum is purely antitoxic in nature. Its influence on the rate of recurrence of erysipelas in patients having frequent attacks of the disease is also of great interest and will be studied further. It is hoped that annoying attacks of serum sickness following the administration of large doses of antistreptococcic serum will be less severe and fewer when the refined globulin serum is used.

GLUCOSE AND INSULIN IN THE TREATMENT OF THE VOMITING OF PREGNANCY

E. L. KING, M.D.
Assistant Professor of Obstetrics, Tulane University of Louisiana School of Medicine
NEW ORLEANS

The intravenous administration of glucose in the treatment of the vomiting of pregnancy was advocated in 1920 by Titus, Hoffman and Givens,[1] who reported the results they obtained in the management of seventy-six cases, the chief factor in the treatment being the free exhibition of carbohydrates. These patients were divided into three groups; the first comprised the cases that could be classed as mild; the second included the moderately severe types, and the third was made up of those patients who were seriously ill.

In the first group were placed thirty-two of these patients. They were treated by rest in bed and free carbohydrate feeding. Small amounts of nourishment were given at frequent intervals, as it was found that the patients could retain seven small meals a day better than three rather bountiful ones. Some of the women also took 1 or 2 ounces (30 or 60 cc.) of a 10 per cent solution of glucose containing 2 per cent of sodium bicarbonate, every three hours. All recovered promptly. In group 2, there were twenty-nine patients. Acetone was found in the urine of each one. They were treated along the same lines as the patients in group 1. Twenty-three patients were relieved promptly, five others recovered more slowly, while the remaining one, though greatly benefited, was somewhat nauseated throughout her pregnancy. The third group comprised fifteen patients who were extremely ill; acetonuria was invariably present, and in the majority of cases albumin and casts were also found in the urine. Many of the patients were jaundiced and all were emaciated; none of them could retain food or water. It appeared that therapeutic abortion would be necessary in the treatment of practically all the patients of this group. They were treated intensively. Fourteen recovered entirely in from seven to fourteen days, while in one case therapeutic abortion was necessary. This patient was jaundiced and emaciated, and was also suffering from multiple neuritis. It is to be presumed that all the patients in group 3 and many in group 2 were treated by the intravenous administration of glucose, though the authors did not go into details with regard to this point.

In 1922, Titus and Givens[2] published a supplementary paper, reporting the same gratifying results in sixty-seven additional cases, with only one death. This patient was one of the two on whom it was necessary to perform therapeutic abortion; she died of acute yellow atrophy of the liver. Eclampsia, preeclamptic toxemia, fulminating toxemia with ablatio placentae, and chorea gravidarum were also successfully treated. In antepartum eclampsia, the employment of glucose intravenously in addition to the usual measures (the cases were handled by the conservative method) reduced the maternal death rate from 28.9 per cent to 15 per cent.

In his latest paper, Titus[3] reports on 184 other patients similarly treated; of these 129 were in group 1. One hundred and two of them were cured in seven days or less; eighteen were entirely relieved of symptoms in from seven to fourteen days, while the remaining nine were cured after a longer interval. The thirty-two patients in group 2 were also promptly relieved. Of the twenty-three in group 3, twenty-one were cured, while two did not improve and died in spite of therapeutic abortion.

In these papers, Titus and his co-workers hold that, while the causation of the nausea and vomiting of early pregnancy is still an unsolved problem, there is no doubt that the mother is suffering from a carbohydrate deficiency, on account of the sudden demand for glucose on the part of the developing embryo. If the mother's diet is rich in carbohydrates, there should be little or no toxemia; but if the diet is deficient in this regard, the needs of the embryo are met by a depletion of the glycogen of the maternal liver. This leads to a fatty replacement in the cells formerly storing glycogen, and later to a fatty degeneration if the deficiency is not corrected. Consequent on this impaired liver function and the resulting toxemia, according to these writers, there develops an acidosis, an increased demand for carbohydrates, and an intolerance for food. Hence, the mother feeds on her own tissues, and a vicious circle is established.

Thalhimer,[4] in 1924, went a step further and began to employ insulin in combination with glucose in the treatment of the toxemic vomiting of pregnancy. He reasons that the acidosis can be combated more readily in this manner than by glucose alone, and quotes Harding and Potter[5] of Toronto as stating that it takes from five to six days to clear up the acidosis in these cases by simple glucose therapy. The insulin promotes the oxidation of the carbohydrate, which is supplied from without as an infusion, the maternal supply being more or less exhausted. Thalhimer reports in detail several severe cases treated in this manner, with most gratifying and extremely prompt improvement in the condition of each patient. He employs 1,000 cc. of a 10 per cent solution of glucose, given intravenously at the rate of from 200 to 300 cc. an hour, which is repeated as indicated. For this administration he has devised a special apparatus.[6] Ten units of insulin is given fifteen minutes after starting (or 20 units may be given at the end of the first hour), and this is repeated at hourly intervals until 30 units has been administered. Epinephrine is to be employed in case a hypoglycemic reaction develops. This occurred only once in Thalhimer's series.

Titus, however, in his latest paper, considers that the use of insulin in combination with the glucose is contraindicated, for the reason that storage in the liver is desired, and not rapid combustion. He treated several patients according to Thalhimer's method, but cannot agree that women thus treated recover more rapidly than those receiving glucose without insulin.

Lefevre[7] reports four patients who were clinically benefited by the use of glucose and insulin. Two were treated early in pregnancy. One of them was cured; the other, after several recurrences which were relieved by this method, finally refused further treatment. She aborted spontaneously one month after her first visit. Another patient was six months pregnant, and the fourth was first seen forty days before delivery. Both were treated successfully. Lefevre employs 50 per cent solutions, giving 10 Gm. of glucose each time; he prefers the concentrated solution on account of the greater ease of intravenous injection. The treatments can be given at the office, and may be repeated daily if necessary. He uses a larger dose of insulin than that recommended by Thalhimer, giving from 10 to 20 or even 25 units with each 10 Gm. of glucose, instead of adhering to the proportion of 1 unit to 2 or 3 Gm. of the glucose. One of these patients, who received 25 units to 10 Gm. of glucose, developed hypoglycemia, which was relieved by orange juice. Lefevre found, in treating the ketonemia of diabetic acidosis, that it is very hard to reduce the blood sugar to a level low enough to bring about insulin shock; he feels, likewise, that the combustion of glucose under the influence of insulin reduces the ketonemia of hyperemesis before the blood sugar level is affected to any appreciable extent.

For the last two years, in the obstetric service of Dr. C. Jeff Miller at the Charity Hospital of New Orleans, we have treated hyperemesis gravidarum along these lines, and it is my purpose here to put on record seven cases thus handled. The number is small, as only the patients suffering from the severer types of toxemic vomiting are admitted to the ward, the ambulant cases being cared for in the clinic. Our results have been much more satisfactory than those obtained when other methods of treatment were employed. The condition of each patient when admitted was so serious that we feared that we would be unable to effect a cure without recourse to therapeutic abortion. In four cases the improvement was so prompt and so striking that resort to this operation was no longer indicated. One patient was hopelessly ill on admission, and died in spite of treatment with glucose and insulin, combined with the induction of abortion. Another patient, who was extremely toxic, was not benefited by this treatment and refused, for religious reasons, the therapeutic abortion that was clearly indicated. She died of toxic myocarditis four weeks after the vomiting had been checked by the use of the duodenal tube. The last patient treated was apparently much benefited, but relapsed, and therapeutic abortion was induced with a resulting cure.

REPORT OF CASES

Case 1.—A woman, admitted, Sept. 26, 1924, in the sixth week of pregnancy, was very toxic. She was treated with phenobarbital sodium, sodium bromide and proctoclysis until October 4, with temporary improvement; at this time her condition changed for the worse. October 4, 5, 6 and 7 she was given 1,000 cc. of 5 per cent glucose solution twice each day by hypodermoclysis with 15 units of insulin each time. October 8, she was much better and retained soft food. October 10, she relished and retained the regular full diet of the ward. Symptoms of threatened abortion then developed, and in spite of treatment with morphine and opium in pill form she aborted, October 21, thirteen days after the cessation of the vomiting. Recovery was uneventful.

Case 2.—A woman, extremely ill, whose condition was hopeless when she was admitted, Oct. 31, 1924, was comatose, with a pulse of 180, marked jaundice, muscular tremors, and involuntary urination and defecation. Glucose was given intravenously, with insulin, once or twice daily. November 4, we started a continuous intravenous drip by the Matas method,[8] giving from 2,000 to 3,000 cc. of 5 per cent glucose every twenty-four hours, with one unit of insulin to each 2.5 Gm. of the sugar. The pulse varied between 160 and 180; only once, November 7, did it drop to 120, and then only for a short time. The urine contained a little sugar at times; the acetone disappeared on the second day, and diacetic acid was never found. November 7, abortion was induced by introducing a catheter without moving the patient from her bed. There was no improvement; terminal bronchopneumonia developed, and she died, November 11. We feel that her life was prolonged by the use of glucose and insulin, and that death was due to the irreparable injury sustained by the organs prior to admission.

Case 3.—A woman, admitted, Jan. 15, 1925, with a pulse of 102, and acetone, a trace of albumin, and some pus in the urine, was very toxic and extremely weak. On the day of admission, 1,000 cc. of 5 per cent glucose solution was given twice by hypodermoclysis, with the corresponding doses of insulin hypodermically. The next day the patient was much worse, and was given 1,000 cc. of 5 per cent glucose solution intravenously, with 20 units of insulin subcutaneously. The following day she was decidedly better. Food was retained, January 18, and thereafter. She was discharged, February 2.

Case 4.—A woman, who did not appear very ill when admitted, Feb. 23, 1925, was given glucose solution, without insulin, February 25 and 26. She retained nothing by mouth. At 2:15 a. m., February 27, the pulse rose to 132, and she became extremely weak. An intravenous injection of 1,000 cc. of 5 per cent glucose solution was given with 10 units of insulin hypodermically. At 8 a. m., the same day, she retained orange juice sweetened with lactose, and later in the day soft food was retained as well. Glucose was given by hypodermoclysis, with insulin, on the evening of February 27, as well as the next day. The convalescence was henceforth uneventful, with only an occasional attack of vomiting, which was controlled by phenobarbital sodium. She was readmitted seven weeks later, with a mild recurrence, which was successfully combated by the same drug.

CASE 5.—A woman, admitted, April 22, 1925, when two and one-half months pregnant, had been vomiting excessively for one week, and appeared to be rather toxic. The urine contained considerable acetone and many red blood cells. She was treated by the administration of 1,000 cc. of 5 per cent glucose solution by hypodermoclysis, with 25 units of insulin, twice daily. The vomiting ceased; the acetone disappeared from the urine, and the patient retained food on and after the third day.

CASE 6.—A woman, admitted, Aug. 4, 1925, when three months pregnant, with a history of occasional vomiting for two months, had become much worse during the two weeks prior to admission. The urine contained considerable acetone. The pulse was over 100 the greater part of the time. The temperature varied between normal and 100 for the first twelve days; after this it rose occasionally to 101 or 102. On the first two days, phenobarbital sodium was administered in 1 grain (0.06 Gm.) doses hypodermically one hour before each meal, but the vomiting persisted. August 6, we began the use of glucose, giving 1,000 cc. of a 5 per cent solution by hypodermoclysis once or twice daily, with 20 units of insulin hypodermically each time. There was temporary improvement, but August 15, the patient became worse, so the intravenous route for the administration of the glucose was employed, the injections being given daily. This treatment was of no avail; hence, August 21, therapeutic abortion was advised. Permission was refused by the patient on religious grounds. We then resorted to the continuous intravenous drip by the Matas method, using 5 per cent glucose solution, with insulin hypodermically. A trace of acetone was still noted in the daily urinalysis. The vomiting continued. August 27, a Jutte tube was passed into the duodenum. The first attempt to pass the tube, one week previously, had failed. The patient was fed through this tube, as suggested by Paddock [9] and the tube was left in place for eight days. There was no vomiting during this time, and for two days before the removal of the tube, she was retaining soft food given by mouth. There was no recurrence of the vomiting after the removal of the tube, and she was soon on a fairly free diet. However, the rapid pulse and general weakness continued. Myocarditis, probably antedating the pregnancy and aggravated by the toxemia, was diagnosed by Dr. J. B. Guthrie of the department of medicine. The myocarditis caused her death, September 22, over three weeks after the cessation of the vomiting.

CASE 7.—A woman, who came to the hospital, Jan. 19, 1926, when about three months pregnant, gave a history of fairly persistent vomiting for one month. For a week before admission her condition had been extremely unsatisfactory, in spite of treatment at home by a competent physician. She had lost 40 or 50 pounds (18 or 23 Kg.). On admission, her pulse was 120 and weak; she was apathetic and fretful, vomited everything, and the urine contained a considerable amount of acetone. The cubital veins were very inaccessible, so the glucose solution was at first administered by hypodermoclysis, with insulin hypodermically. She improved very decidedly for the first sixty hours; the acetone disappeared from the urine, and she retained some soft food. Her condition then became worse, so the intravenous route was resorted to, 1,000 cc. of a 10 per cent solution being given each time. In spite of this treatment, she became progressively worse and retained nothing. January 25, her pulse was 140, and the prognosis was not good. Catheters were inserted that night, and she aborted on the morning of January 27. After this she improved gradually but steadily; her pulse, however, remained rapid for several days. She was discharged, February 8.

COMMENT

It will be noted that the patients in this series who were benefited by the glucose therapy responded promptly to the treatment, and that the one who was hopelessly ill (patient 2) and the two other extremely ill patients derived only transient benefit or none at all. Hence, it would appear that therapeutic abortion is the only alternative when these severely toxic patients do not show prompt and striking improvement after intravenous glucose therapy has been employed. In these patients, the injury to the liver and other vital organs is evidently so extensive that prompt removal of the source of the toxin or toxins is the only measure promising relief, and if the toxemia has progressed too far, even this treatment will not avail.

Another lesson to be learned from this small series is that it is best to resort to the intravenous route from the start in caring for seriously ill patients, even though we treated two (patients 1 and 5) successfully by the administration of glucose by hypodermoclysis only. These two were not so ill as the other five. It is probable that in one or two instances we lost valuable time because we did not employ the intravenous method from the outset. I would also recommend that the continuous intravenous drip of Dr. Matas be given a more extended trial, particularly in desperate cases. Of course, if facilities for intravenous treatment are lacking, the subcutaneous method is to be employed.

Another point of interest is the fact that in case 6 treatment by the duodenal tube succeeded, as far as controlling the vomiting was concerned, after the intravenous administration of glucose had failed. We have attempted to pass the tube several times in patients not included in this series, but failure has been the rule. It appears that this method has great merit, provided one is so fortunate as to succeed in passing the tube through the pylorus. The frequent vomiting makes this difficult, and at times impossible.

For the sake of brevity, I omitted from the case reports all reference to the blood chemical determinations. We found that the maternal blood sugar was uniformly low before beginning treatment, and that it rose promptly after the administration of glucose and insulin. We have not attempted the study of the glycemia curves as a test of the extent of liver injury, as outlined by Titus and Givens,[2] but it appears that this is a useful and reliable method. From a practical point of view, we have noted that repeated punctures of the veins soon result in thrombus formation, and thus the veins available for the introduction of the glucose are rendered useless. Hence, we have not deemed it advisable to resort to daily blood sugar determinations, however interesting such a study might be.

From this small series, it appears justifiable to conclude that this method of treatment is of decided value, and constitutes a definite advance over the methods formerly employed for the relief of patients suffering from the toxemic vomiting of pregnancy. I feel that the use of insulin with the glucose is to be preferred, as my impression is that more prompt relief is thus obtained than by the employment of glucose alone. However, an occasional patient will be encountered with organic injury already so extensive that this treatment will be of no avail, and therapeutic abortion will be the only recourse. This point can be determined at present only by clinical observation. It is possible that one or more of the various liver function tests may be found of great value in assisting us to arrive at a decision in such a case, but more investigation is necessary along this line[10]

MADISON, WIS.

Since the summer of 1922 one of us (P. M. D.) has periodically been in charge of the inmates of a girls' camp among the Rocky Mountains The high altitude of the camp (9,000 feet) and the naturally strenuous nature of the most important local activity (mountaineering) rendered desirable some reliable or at least suggestive test of cardiovascular efficiency. Routine examinations and grading by the method devised by E. C. Schneider[1] were therefore instituted and proved to be very helpful. There was, however, no body of observations that could serve as a guide and establish the limits of normality for the Schneider grades in girls. Consequently, three of us (M. K. D., D. M. and M. M.) undertook to supply this demand and the results of our observations are the basis of this article.

The cases studied by us are not very numerous (200), but we believe that our results will be welcomed as suggestive and helpful by those, whether physicians or physical directors, who are engaged in supervising the physical activities of girls.

METHOD

In ordinary speech one uses the designation "athletic girl" rather vaguely. Sometimes one is thinking of a girl who is engaged in athletics, sometimes of a girl of good physique; sometimes the individual one has in mind possesses both of these characteristics. In this paper the terms in question are used to indicate girls who are actively engaged in athletic sports regardless of their physique. To be sure, a good physique is as a rule associated with athletic activities either as cause or effect or both; but this is not necessarily the case and it may be that some of the girls whom we have designated athletic were physically below par, while some of those designated nonathletic may have been more physically efficient than some of the so-called athletic ones. If this should happen to have been the case, the fact need not cause us any concern, for the only result would be a tendency for differences found between the athletic and nonathletic to be reduced and consequently such differences as may have been found would come to have greater significance.

Our mode of procedure was to observe and compare the cardiovascular reactions of athletic and nonathletic girls (as defined above) as shown by the Schneider and Crampton[2] tests.

Briefly stated, the factors entering into these tests are: Schneider's: A, pulse rate while lying; B, difference between A and C; C, while standing; D, increase resulting from standard exercise; E, time required to return to normal after such exercise; F, change in systolic pressure on passing from lying to standing. Crampton's: B and F of the preceding test.

The subjects of our observations were 200 high school girls in Manitowoc and Madison, Wis., and Prophetstown, Oak Park and Hinsdale, Ill. In respect to the data obtained, these subjects fall into two groups, 1 and 2. In group 1, the diastolic as well as the systolic pressure was determined and the subjects were classified according to age. This group comprises sixty nonathletic and forty athletic girls whose ages range from 13 to 19 years, inclusive. In group 2 the diastolic pressure was not determined and there was no distinction made as to age. This group comprises fifty athletic and fifty nonathletic girls of from 13 to 15 years of age, inclusive.

For the convenience of those employing the tests in question, our results are presented in tabular form. Through the perusal of these tables we have been led to a series of conclusions which we shall enumerate, stating after each member of the series the table or tables that establish the conclusion in question. The conclusions are not of equal validity, since for some of them the number of cases examined is inadequate. This circumstance need not mislead the reader, since the details necessary to evaluate each conclusion are always stated in the particular table to which reference is made. Throughout these conclusions the comparative degree is used in speaking of the athletic girl as contrasted with the unathletic.

CONCLUSIONS

Some of the conclusions are of questionable importance and validity.

1. Athletic girls have a slightly larger increase in pulse pressure after passing from the recumbent to the erect posture (table 2).
2. Their average diastolic pressure rises slightly higher under the same circumstances (table 2)
3. Their average diastolic pressure falls slightly lower after exercise (table 2).
4. Their systolic pressure rises slightly higher as the result of exercise (table 2).
5 Their pulse product is a little less in both lying and standing and a little greater after exercise (table 1).

Some of the conclusions are neither new nor unexpected.

6. Athletic girls have a slower resting pulse than the nonathletic (table 1).
7. They have a greater rise of systolic pressure on passing from the recumbent to the standing posture (table 2).
8 They have a smaller increase in pulse rate on passing from the recumbent to the standing posture (table 2).

---

[10] The glucose solutions are prepared at the Charity Hospital as follows Chemically pure, anhydrous dextrose is used, of the best quality obtainable It is dissolved in sterile distilled water and is strained through sterile gauze into sterile pint bottles All utensils are sterilized before being used The bottles, after being filled, are placed in an ordinary sterilizer and are boiled for fifteen minutes In my experience, no reaction has followed the employment of solutions thus prepared, nor have I heard of untoward results occurring in other departments of the hospital It might be well to note the fact that ampules containing concentrated glucose solutions are now available, from which the weaker solutions are made by simple dilution

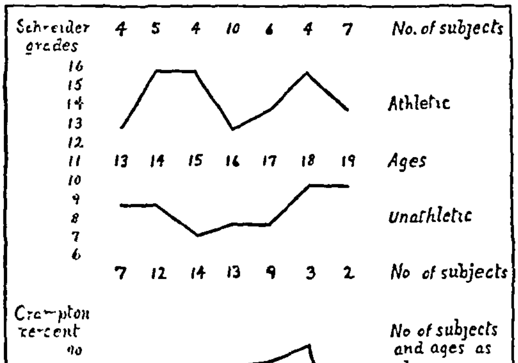
* The table is read thus: 8 indicates that 8 per cent of the thirteen athletic girls of from 13 to 15 years of group 1 have a Crampton percentage of 105.



Average Schneider grades for the various ages mentioned and also the average Crampton percentages. This refers to group 1 only.

16. Nonathletic girls having a Schneider grade of less than 6 have usually a Crampton percentage of not more than 85, though it may be 100 or even 122 (table 5).

17. Nonathletic girls having a Crampton percentage of 65 or less do not have Schneider ratings of more than 12; 55 per cent. 9 (table 5).

18. One may expect a fall in the Schneider grade at the ages of 15 to 17 inclusive in both athletic and nonathletic subjects (chart).

19. A similar decrease occurs in the Crampton percentage, but only in the case of nonathletic individuals (chart).

20. Girls with a Schneider grade below 6 or a Crampton percentage below 70 should receive especial care (tables 3 and 4).

21. In athletic girls the various Schneider factors have a superiority over those of the nonathletic in the order A, D, B-E, C, F, and it would therefore seem that factors A and D are of the greatest importance as criteria of physical efficiency, while C and F are of the least importance (table 6).

[3]
$$\frac{\frac{\Sigma\,(xy)}{n} - Mx \times My}{\sqrt{\frac{\Sigma\,x^2}{n} - M^2x} \times \sqrt{\frac{\Sigma\,y^2}{n} - M^2y}} = r$$

In this equation Σ is sum of; x, Schneider's grades; y, Crampton's percentages; n, number of subjects; Mx, mean or average of x; My, mean or average of y; r, coefficient of correlation of x and y. By means of this equation the forty athletic and the sixty unathletic girls of group 1 were found to have coefficients of + 0.38 and + 0.296, respectively.

* The table is read thus 46 indicates that 46 per cent of the athletic girls of 13 to 15 years of group 1 have a rating of 3 in respect to factor A of the Schneider test

22 The study of the distribution of grades in respect to the various factors of the Schneider test indicates that in order of decreasing physical efficiency we have athletic 13 15, athletic 16-19, nonathletic, 13-15, nonathletic 16-19 (table 7)

On perusal of these twenty-two statements, one is led to try to picture to oneself the athletic girl, and, bearing in mind that we shall continue to use the comparative degree always with reference to the unathletic girl, we may thus speak of the athletic girl:

As for the increase of her pulse pressure on standing, the rise of her diastolic pressure under like circumstances, the rise in systolic pressure and the fall in diastolic found after exercise, the values of her pulse product whether lying, standing or after exercise, the athletic girl differs but little (if at all) from her unathletic sister. On the other hand, her resting pulse is slower, her pulse pressure larger; on rising from recumbency her pulse quickens less, it is less after exercise, and it returns more promptly to normal Her Schneider rating is not less than 6 and her Crampton percentage not less than 55 If her age is between 15 and 17, one might expect to find her Schneider rating near the lower level of her class

That neither Atalanta nor Penthesilea would recognize herself in this description need not surprise us Their point of view was different from ours.

A SPECIFIC INHIBITORY HORMONE OF THE CORPUS LUTEUM

ITS CONTRAST WITH THE FEMALE SEX (FOLLICULAR) HORMONE *

GEORGE N PAPANICOLAOU, PH D, M D

NEW YORK

The corpus luteum, in its function as an endocrine gland, has a definite inhibitory effect on ovulation and menstruation or estrus. The suppression of these phenomena during pregnancy is an example of this effect The removal of the corpora lutea abolishes this inhibitory effect and accelerates the appearance of the next period, as was first demonstrated experimentally by Leo Loeb[1] In experiments performed along similar lines with guinea-pigs, I[2] found that after complete removal of the corpora lutea the ovulation and estrus return on the eleventh day, while in normal guinea-pigs estrus usually returns at the fifteenth or the sixteenth day These findings indicate that the corpora lutea exert an inhibitory action, suppressing and delaying the process of ovulation in the rhythmic function of the ovary

I have used this inhibitory function of the corpus luteum as a criterion for studying luteal extracts and especially for the recognition of the specific luteal hormone

The guinea-pig is a particularly suitable animal for such an investigation, on account of the regularity of its estrual cycle The use of the vaginal smear examinations[3] makes it possible to detect the return of estrus in a very exact way Numerous animals have been killed at different periods for the study of the ovaries and other genital organs

[2] Papanicolaou, G N Anat Rec, 1921

[3] Stockard C R, and Papanicolaou, G N Am J Anat 22:225 (Sept) 1917.

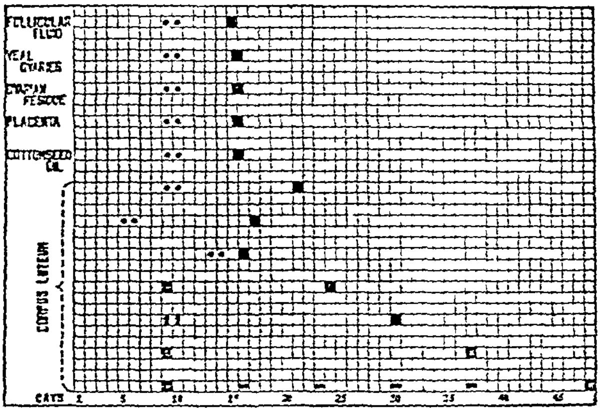
The animals employed in this work have been first tested in regard to the regularity of their estrual cycle and then given injections of various luteal and other ovarian extracts.[4] A lipoid luteal fraction was soon found to give positive results, causing a definite inhibitory effect and delaying ovulation and estrus for a period of several days.[5]

Some of the purified extracts have been highly efficient in their inhibitory effect. An unmistakable delay follows each injection of this hormone given in small quantities of from 1 to 2 cc. By giving weekly one injection of from 1 to 2 cc., it is possible to suppress the process of ovulation indefinitely. Through such a procedure, I have been able to suppress ovarian rhythm in several animals for a period of from two to four months. At the end of this period the injections were discontinued, and ovulation reappeared several days after the last injection. The ovaries of animals killed after long suppression show a complete absence of corpora lutea and a large number of middle sized follicles with a highly congested theca interna. This congestion of the theca interna causes an early atresia and prevents the follicles from enlarging into mature graafian follicles. The old corpora lutea degenerate gradually, and the ovary becomes practically free of luteal tissue. The full growth of the follicles and the process of ovulation are thus suppressed, and the ovary thereby loses its cyclic rhythm. This effect is evidently specific and is caused only by the subcutaneous administration of luteal extracts. Similar extracts prepared from other parts of the ovary (follicular fluid, cystic fluid, ovarian residue) and from other organs (placenta, thyroid, thymus, testes and immature ovaries) in all cases gave negative results. It seems evident that this particular hormone is typical for the corpora lutea.

The accompanying chart illustrates the effect on ovulation and estrus of extracts all prepared by the same method from follicular fluid, veal ovaries (prepubertal ovaries having no corpora lutea), ovarian residue (after complete removal of corpora lutea), placenta and corpora lutea. The effect of cottonseed oil, which has been largely used as a solvent, is also recorded. This chart shows that all the extracts, with the exception of the luteal, fail to delay ovulation, which returns at the expected time; i. e., the fifteenth or sixteenth day. Much larger doses than those recorded in the chart also gave negative results. The luteal extracts, on the other hand, cause a definite delay. The injection of 1 cc. each on the ninth and tenth day delayed ovulation for five days in the case recorded in this chart. When similar injections are given much earlier, or much later—for instance, the fifth or sixth or the thirteenth or fourteenth day—the delay is less pronounced. The best results have been obtained when the injections were given about a week before the expected ovulation. A larger dose produces a longer delay, as is shown in the chart after the injection of from 4 to 6 cc. Injections given on two or more consecutive days seem to be more effective than a single injection of the combined amount. The continuous administration of luteal hormone at regular intervals delays ovulation indefinitely. In the case recorded in the chart, 4 cc. was given at first and then 2 cc. weekly for four weeks, after which the injections have been discontinued. The ovulation returned at the forty-eighth day; i. e., eleven days after the last injection. If these injections had been continued, the ovulation would have been longer delayed.

The uniformity of results obtained with a large number of tests leaves no doubt that we possess a very simple method of recognizing, isolating and standardizing the proper luteal hormone.[6] No confusion seems possible between this hormone and the female sex (follicular) hormone The female sex hormone itself has been repeatedly identified in the corpus luteum, especially in its early stages, in the luteal fluid and in the luteal cysts[7] This fact has caused a great deal of confusion. The corpus luteum is evidently able to secrete both hormones the female sex hormone is probably secreted by the undifferentiated theca or granulosa cells, while the specific luteal hormone is probably formed by the fully differentiated luteal cells, the latter increasing in number with the advancing differentiation and development of the corpus luteum.

Such a view is supported by the recent experimental work of Zondek and Aschheim.[8] These authors have implanted late postmenstrual corpora lutea in spayed mice and have found that no female sex hormone reaction has been induced on the genitalia. On the other hand, premenstrual and menstrual corpora lutea as well as theca cells have given a positive reaction. The failure to recognize that two different hormones may exist in the corpus luteum, and the lack of proper methods for their separation and study, have been a continuous source of confusion. Most investigators have used and are still using the standard castration test[9] for their work with luteal extracts. Such a



The inhibitory effect on ovulation of injections of a similar lipoid fraction extracted from (a) follicular fluid, (b) veal ovaries, (c) ovarian residue, (d) placenta, and (e) corpus luteum. Cottonseed oil was also injected as a control Each black circle indicates one injection of 1 cc. The black squares indicate the day of the following ovulation method prevents one from discriminating between the proper luteal and the female sex hormone. Positive as well as negative results have been reported, indicating that the female sex principle may or may not be present within the corpora lutea.

---

[4] These extracts were first prepared at the Loomis Laboratory by N. F. Blau, in cooperation with John D Rogers Later, I have used highly purified and more efficient extracts prepared by the Eli Lilly Research Laboratories

[5] Papanicolaou, G N: Proc Soc Exper. Biol & Med. **22**: 106, 1924

[6] The minimum amount of extract required to postpone the ovulation of guinea pigs for five days when given in two equal injections on the ninth and tenth day after the preceding ovulation, has been considered as the equivalent of 5 units Thus, one unit theoretically represents the amount required to postpone the ovulation of a normal guinea pig for one day It is preferable to standardize these luteal extracts on a 5 unit rather than a 1 unit basis because the postponement of ovulation for one day falls too closely within the limits of normal variability

[8] Zondek, B, and Aschheim S Klin Wchnschr **4**: 1388 (July 16) 1925

[9] This method consists in the removal of both ovaries and then testing the effect of extracts on the genital tract. This method has been improved by Allen and Doisy with the introduction of vaginal smears

The proper luteal hormone and the female sex hormone act in an entirely different way from each other and are, to a certain extent, antagonistic. The luteal hormone inhibits and delays ovulation and estrus, whereas the female sex hormone rather accelerates these processes to a limited extent. The luteal, in a purified state, does not excite estrus and does not cause hypertrophy in the genital tract of spayed females, as the female sex hormone does to a striking degree. Both are active during pregnancy, but act in different manners. The one inhibits, the other stimulates. The two, however, act simultaneously. The oral administration of extracts containing the luteal hormone gave no results, though large doses have been used. From a practical point of view, this method of administration cannot be utilized at present.

GENERALIZED ALOPECIA

REPORT OF THREE CASES, WITH ONE NECROPSY *

GEORGE WILSON, M.D.
AND
N. W. WINKELMAN, M.D.
PHILADELPHIA

The universal loss of hair from the body has occasionally been described in medical literature and, although no constant etiologic factor is present in such a condition, various causes have been ascribed, most of them on theoretical grounds. Alopecia areata infrequently produces a universal falling out of the hair. In syphilis loss of hair occurs, but it is seldom complete; Chambers,[1] however, in 1901 reported the case of a woman, previously treated for interstitial keratitis, whose hair fell out in patches when she was 5 years old, but it returned in a short time. At the age of 12, her hair began to fall out again, and with the exception of two small, fine ones on the anterior portion of the scalp, she had no hair on the entire body at the age of 20. Arnett[2] cited a case which he thought was due to syphilis; the patient was 26, and had lost his hair eight years previously; the Wassermann reaction was strongly positive, and at the end of seventeen months of antisyphilitic treatment the hair was entirely restored. This patient had had two previous attacks, one at the age of 6 and the second at the age of 12, and in both the hair returned with the employment of only local measures. Thompson's[3] case occurred in a man, aged 23, who, two months after the appearance of a chancre, lost all his hair and four years later there was no return. Alfred[4] saw a case of generalized alopecia, which apparently had resulted from scarlet fever in early childhood. Sajous[5] reported the case of a woman, aged 30, otherwise in good health, who in less than a week lost the hair of the entire body, not even an eyelash remaining. Different lines of treatment were used over a period of two years, and the only one that proved effective was a capsule containing 1 grain (0.06 Gm.) of thyroid extract, 2 grains (0.13 Gm.) of suprarenal extract and 2 grains of iron given three times daily. Sajous says that this was "effective," but he does not say restoration of hair occurred, although it is presumed that this is what he meant.

According to Stelwagon[6] thallium, if given for a long time, will produce universal loss of hair. Buschke and Peiser[7] fed young rats on bread dipped in a 1 : 5,000 solution of thallium acetate, and the rodents lost all their hair in a month. In addition, their growth was stunted and they presented a cretin-like appearance. These writers believe that the endocrine glands showed a selective toxic effect, and the whole organism suffered secondarily through intermediation of the ductless glands. Experiments on tadpoles with thyroid treatment to counteract the thallium have been confirmatory of this belief. In the treatment of epilepsy with borax, Féré[8] said that it is not rare to see a generalized alopecia produced.

Localized loss of hair may be due to the injury of a nerve or posterior root. In 1886, Max Joseph[9] demonstrated that section, in an animal, of the posterior branch of the second cervical nerve, between the ganglion and the cord, produced an alopecia in the area supplied by this nerve. This was confirmed by observers in 1887 and 1888.

There undoubtedly is a close relationship between the glands of internal secretion and the sympathetic system, in regard to the growth, character and changes in the hair. Like so many things in endocrinology there are few, indeed, proved facts in regard to the influence of the glands of internal secretion on the sympathetic system and the hair. It is well known that disturbances in the growth and character of the hair occur in certain diseases of the ductless glands, such as myxedema, exophthalmic goiter, Fröhlich's syndrome and tumors of the suprarenal, but the exact mechanism by which the changes are produced is not known. The hair changes in pregnancy and at puberty are also dependent on the endocrine glands.

Pulay[10] states that at the menopause, either natural or surgical, while the hair falls from the scalp, there is simultaneously an increased growth on the face, and he believes that this is due to cessation of action of the ovaries and decreased function of the pituitary.

C. Todde[11] cited the case of an officer, aged 34, who, following the stress of living at the front and after weeks of incessant bombardment, lost every hair on his body. This man also presented symptoms suggestive of exophthalmic goiter. Todde's case is similar in some respects to our second case.

Meachen and Provis[12] reported an instance of generalized alopecia cured by pregnancy, which relapsed with the reestablishment of the menses. The patient was 31, had been married eight years, and had had four children and two miscarriages. In the sixth month of her second pregnancy the hair began to fall, and

when the child was 5 months old she "hadn't a hair on her head." During the third pregnancy the hair grew, nearly all of it returning. Then a stillbirth occurred, and when the periods reappeared the hair fell out again; this time all the hair of the body disappeared. She became pregnant again, and from the first month of the pregnancy the hair began to return, so that she had a splendid crop except in two small patches. When this child was 5 months old, the hair once more fell out and the finger-nails also became affected. March 26, 1912, when Meachen and Provis saw her, the scalp was bare, except for a few scanty strands of rather coarse black hair. The eyebrows and eyelashes were absent, although the remaining parts of the body were not absolutely alopecic. The finger and toe nails were lusterless and longitudinally striated, and presented numerous fine pits, especially on the lunulae. At the time of their presentation of the patient, June 20, 1912, the scalp was totally bald, and the other parts of the body were also denuded. The patient presented no signs of syphilis, but a Wassermann reaction of the blood had not been taken. In the discussion of this case, Sequeira said that he has seen several cases in which there had been a complete loss of hair after delivery, and he had under his care at that time a woman who had lost her hair on three occasions. The hair returned between the first two pregnancies, but after the third the loss of hair was permanent. He also had under his care at that time a second patient, who had complete alopecia after delivery but when seen twelve months later, the hair was returning.

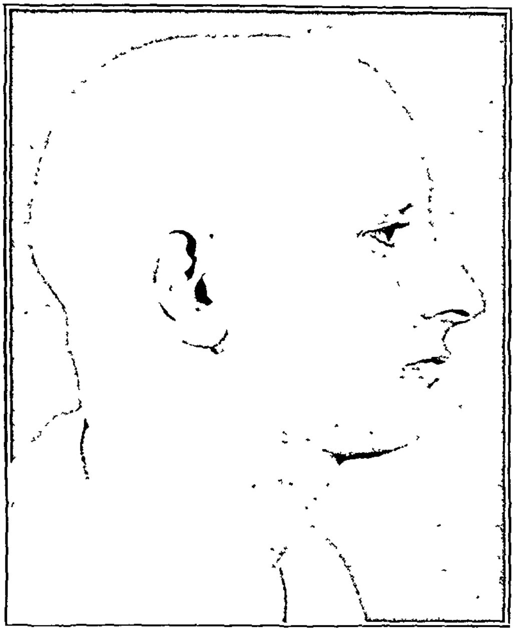

Fig. 1 (case 2).—Loss of hair from scalp and eyebrows as result of alopecia.

Eddows[13] exhibited a patient showing generalized alopecia, leukoderma and scleroderma. The universal alopecia came on after an attack of scarlet fever at the age of 8. Nothing new occurred until the boy was 14, when he awoke one morning with itching hands and shortly after he noticed that his skin was becoming brown. At the time of presentation, the patient was entirely piebald. Large patches of leukoderma were at that time encroaching on all the brown areas. Improvement occurred under the administration of thyroid extract.

REPORT OF CASES

The cases reported here are instructive in the consideration of generalized alopecia:

Case 1.—*History.*—A white woman, aged 49, admitted to the Episcopal Hospital, March 7, 1923, complained chiefly of general weakness. The family and personal histories were negative, with the exception that eight years before admission to the hospital, she had had a complete hysterectomy. She had never been married or pregnant. The onset of the trouble was one year after the operation (or seven years previously), when the patient began to have severe headaches. At this time the hair of the body commenced to fall out, and in six months all of it had disappeared. Three or four months before admission to the hospital, a few hairs returned on the front of the scalp. Shortly after the appearance of the headaches, she suffered from generalized convulsions every five or six months; in these attacks she was unconscious, bit her tongue, had relaxation of the sphincters, and slept for several hours afterward. The last fit was a year before her admission. During the last year, she had severe frontal headaches, which were sudden in onset, lasted from five to ten minutes, and were accompanied by nervousness and anxiety. About two months before admission, she had an attack of influenza, from which she made a poor recovery, muscular weakness being so pronounced that she could not walk, and because of this she lost ambition and desired to be left alone. Following the attack of influenza, she was very nervous and so "shaky" that she could not lift a glass of water without spilling it. She had neither pulmonary nor cardiac symptoms and said she had not lost weight.

Examination.—The woman was thin and undersized, and lay in bed apparently suffering no pain, although she was nervous and apprehensive. The skin was dry and putty colored. Eight teeth remained, and the tongue was soft and flabby. The lungs, heart and abdomen were normal, except that the right kidney was palpable. All the hair of the body including the eyelashes was absent, with the exception of a small tuft on the anterior portion of the scalp. The deep reflexes, ocular nerves and pupils were normal. No ataxia was present in the finger to nose test, although a coarse intention tremor was easily brought out in both upper extremities, especially on the right. Extreme asthenia was present, so that the patient was unable to repeat an act any length of time, in this way resembling a case of myasthenia gravis. The systolic blood pressure was 95; diastolic, 65. The temperature was subnormal practically throughout the hospitalization. The eye examination by Dr. F. Krauss revealed a primary, bilateral optic atrophy.

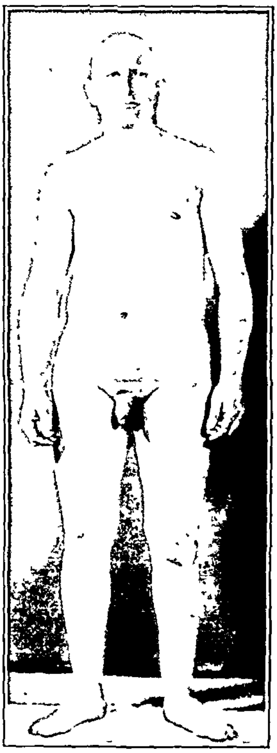

Fig 2 (case 2).—Complete loss of body hair.

The urine was normal, with the exception of an occasional cast and on two occasions a faint trace of albumin; it was reduced in amount, on one occasion measuring 240 cc. in twenty-four hours and on another 775 cc. The routine blood and Wassermann examinations were negative. The blood sugar was estimated on two occasions; the result of the first examination was 30.42 mg. per hundred cubic centimeters and the second, 54.8 mg. The spinal fluid was normal, and the roentgenogram of the skull and sella turcica was negative

---

[13] Eddows: Brit J. Dermat **11**: 325, 1899.

Clinical Course and Outcome.—Seventeen days after admission the patient had a severe headache, which was promptly relieved by an ordinary headache powder. Two days later she had a similar headache, and in this became nervous and agitated. On the day before she died she complained of headache, was drowsy and ate practically nothing all day. Spinal puncture was done late on this day, and she died suddenly at 5 o'clock the next morning.

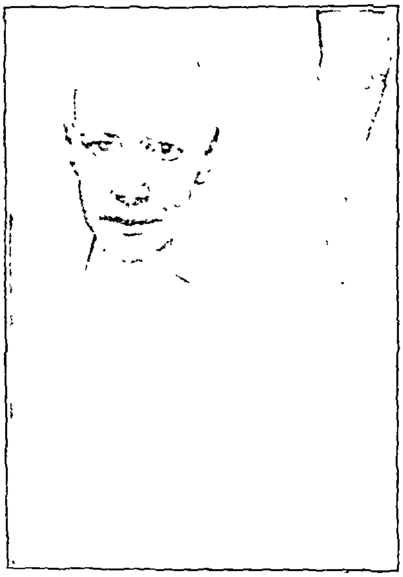

Fig. 3 (case 3).—Loss of hair on head and [illegible]

Pathologic and Microscopic Reports.—Necropsy was performed five hours after death. The skull was normal, except for a carious condition and enlargement of the sella turcica. The brain and ductless glands were removed for study. The brain was rather large, especially in its lateral diameter, and the convolutions were flattened. The pia-arachnoid was thin and translucent: little vascular sclerosis was present. Bulging of the third ventricle was especially looked for, but could not be made out. On transverse section, it was found that the posterior portions of the lateral ventricles were dilated; the anterior division was filled with a soft, discolored mass not attached to the ventricular walls on the left, but adherent to the under surface of the corpus callosum and the walls of the right lateral ventricle. Both caudate nuclei were compressed. The tumor extended into the right frontal lobe, where it expanded into a mass 3 by 2.5 cm. The right island of Reil was involved and the third ventricle was filled with tumor tissue, but the neoplasm did not extend to the bottom of the third ventricle. Microscopic study of the growth showed it to be a typical glioma. Microscopic study of the tuber cinereum revealed a distorted but comparatively normal structure.

The pituitary, examined by Dr. E. B. Krumbhaar, was large; acidophilic hyperplasia was noted in the center, with a cyst containing degenerated cells and coagulated material, lined with tall columnar epithelium, with invasion of round cell nuclei in the immediate vicinity. Small hemorrhages could be made out. The suprarenal was in the resting stage and showed slight interstitial irritation. The pancreas was the seat of moderate fatty infiltration. The thyroid, parathyroids and pineal were normal.

Case 2.—A white man, aged 31, stated that he first observed a gradual loss of hair over the entire body after undergoing some harrowing experiences in France during the war, and within a few months the entire body was denuded of hair with the exception of the eyelashes and one or two small, fine hairs on the upper lip; an increase in weight was also noted.

When we saw him, five years later, the patient presented the picture of a complete alopecia, with the exception of the eyelashes (figs. 1 and 2). In addition the skin was soft and velvety: the breasts were slightly enlarged and he was 20 pounds (9 Kg.) above his usual weight. The gonads were small. In all other respects, the general physical examination was negative. A roentgenogram of the sella turcica was negative, and the blood chemical findings were within normal limits, the blood sugar being 80.

Case 3.—*History.*—A waitress, aged 33, unmarried, admitted to the Episcopal Hospital, May 21, 1925, born in Norway, had been in the United States sixteen years. The past history was unimportant. The menses were normal and she had never been pregnant.

Her chief complaint was loss of hair over the entire body. In August, 1923, she noticed some bald spots on the back of her head. By Christmas of that year, all the hair had disappeared from the head, eyebrows, eyelashes, and the hair from the rest of the body disappeared soon afterward. She had lost 40 pounds (18 Kg.) since the onset of the trouble. She had had various lines of treatment, but nothing seemed to cause a return of hair.

Examination.—The patient was tall, angular and emaciated. Physical and neurologic examinations were entirely negative, except that all the hair of the body was absent (figs. 3 and 4). The roentgenogram of the sella turcica revealed no evidence of abnormality. The eye grounds and fields were normal. The temperature showed little if any deviation from the normal throughout the stay in the hospital. The urine and spinal fluid were normal. The blood chemical findings and blood Wassermann reaction were negative. The blood count was not unusual, with the exception of an eosinophilia of 6 per cent. for which no cause could be found.

A piece of scalp was removed and submitted to Dr. Fred D. Weidman, professor of dermatologic research at the University of Pennsylvania, who found that the plane of excision from the scalp had passed through the deepest parts of the corium.

Epiderm: The uppermost parts of the stratum corneum were loose, but the layer as a whole was thin. The granular layer was likewise thin, and its cells appeared normal. The prickle layer averaged four or five layers of large, normal appearing cells with large spherical nuclei. The intercellular spaces were normal, prickles being recognizable only on careful search. The basal layer consisted of only one or two layers of cells; these were not quite normal in appearance, because they conformed so closely to those of the prickle layer. Thus, they averaged larger in size; the nuclei were large and not particularly elongated, and the chromatin was not condensed. The interpapillary pegs were, if anything, less highly developed than normal. On the whole, the epiderm seemed to be, clinically speaking, thin, soft and supplied with a full amount of watery material, the latter, of course, bound up with the protein molecule (hydrophil colloid).

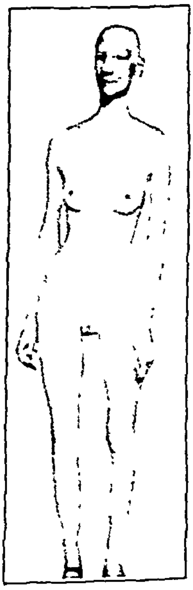

Fig. 4 (case 3).—Loss of body hair.

Corium: The pars papillaris appeared normal. The collagen bundles of the deeper parts took on the appearance of being separated into sectors by reason of the looseness of perivascular, perifollicular and perisudoriferous fibrous tissues. In the latter positions, the spindle cells were swollen and notably hyperplastic; only small numbers of lymphocytes were intermixed. The blood vessels (capillaries were the only ones included in this section) were numerous, and appeared in these sections in clusters. Dr. Weidman did not believe that this was the effect of tortuosity but rather of multiplication. Their lining cells were plump and hyperplastic. As indicated above, they were surrounded by a loose reticulum, on which goodly numbers of swollen spindle cells were disposed.

Hair Follicles: These generally occurred in groups of three or four. They were numerous. The most conspicuous feature consisted in the absence of the hair shaft; in its stead a loose, pink, fibrillar material appeared, which was identical in appearance with the corneous substance on the skin surface. The sheath consisted, on an average, of eight or ten layers of cells, and was a replica of the surface epiderm. Thus, those parts of the follicle which lay closer to the surface exhibited a most sharply and fully developed stratum granulosum; if anything, a basal layer was better indicated here than on the surface. However, no prickle cells could be made out. In deeper portions of the follicle, there was a delicate, threadlike, hyaloid (but doubtless keratinous, chemically) zone lining the lumen of the hair follicle. Its wavy contour reminded one of the elastic membrane in arteries and perhaps of the cuticle-like lining of sweat ducts. It is regretted that none of the bulbs of follicles were included in these sections.

Sebaceous Glands: These were most inconspicuous for a position like the scalp, although they might have been more fully represented if deeper portions had been available for study. As it was, only small groups of cells adjacent to the hair follicle could be found. Those that were exhibited appeared normal.

Sweat Glands: Again, since the examination was restricted to the upper portions of the scalp, the deeper parts, such as the secreting coils, were not represented. Ducts, however, were numerous. The lumina were narrow and their lining cells plump and of normal appearance.

Comment and Summary: No exceptions could be taken against the epiderm; if anything, it appeared to be biologically more active than normal. The important changes were those of the hair shaft, together with the assumption of epiderm-like qualities on the part of the sheath. The second significant feature was the hyperplasia of the capillaries and of the spindle cells around them; but there was nothing to indicate whether this was a primary or secondary factor in the case. The same was true of the scarcity of sebaceous glands, but in this case the explanation was at hand in the form of the secondary atrophy of disuse.

Supplementary Note: In subsequently cut sections, the lowermost portions of some hair follicles were presented for study. Now the whole follicle was less than half the size of those elsewhere, and easily overlooked. The peripheral parts of the sheath merged with the surrounding loose fibrous tissue by reason of an edema, which affected both of these members. The sheath consisted of only two or three layers of cells, the basal ones not being recognizable as such. The center of the follicle consisted of some pink, probably keratinous substance, enclosing numerous epithelial nuclei. The latter were degenerate—some were swollen and pale, while others were shriveled, solid and almost black. Small numbers of lymphocytes and one or two polymorphonuclears appeared in the neighborhood of these follicles. The appearance was not that of an inflammation and fibrosis which was inducing an atrophy of the follicle, but more that of a primary atrophy. The surrounding loose fibrous tissue and minor cellular infiltrate might be interpreted as reactions to disintegration products of the hair shaft that were once present.

The histologic diagnosis was atrophy of the hair follicle and sebaceous glands and "epidermization" of hair follicle.

SUMMARY AND CONCLUSIONS

These three cases are examples of generalized alopecia. In the first, the condition came on one year after a complete hysterectomy, with the coincident occurrence of symptoms that were due to brain tumor. The fact that removal of the ovaries usually produces hypertrichosis and also that the alopecia did not occur until one year later would militate against the possibility that the condition was ovarian in origin. The situation of the brain tumor directly over the pituitary and in the third ventricle produced erosion of the sella turcica which, with the low blood sugar and hypotension, was suggestive of a disturbance of function in the region of the infundibulum or pituitary, or both.

In the second case, the symptoms came on after severe emotional stress and here, too, there are symptoms referable to the pituitary region, although not necessarily a tumor. It may be said by some that emotional stress is incapable of producing such a marked disturbance of a ductless gland, yet we have seen exophthalmic goiter develop in a woman shortly after she had nearly drowned. Furthermore, the so-called neurocirculatory asthenia or effort syndrome which in certain cases may be of endocrine origin occasionally comes on after severe fright, and in this group of cases disability persists for many years. Other cases of universal alopecia following emotional stress have been recorded; thus, Sabouraud [14] described a case of profuse alopecia in a girl, aged 13, who lost her hair thirteen days after being raped, although the hair returned later. Boisser, Bidon and Morris [15] have all cited cases of generalized alopecia coming on after severe emotional stress.

The cause of the alopecia in the third case is unknown to us. In this case, as in the second one, we tried various glandular extracts over a period of one year but without results.

PUERPERAL FEVER

III. A COMPARISON OF THE INCIDENCE OF THE SKIN REACTIONS OF THE TOXINS FROM HEMOLYTIC STREPTOCOCCI FROM PUERPERAL AND SCARLET FEVER *

ABRAHAM F. LASH, M.D.
CHICAGO

The production of a toxin by *Streptococcus hemolyticus* isolated from the blood of patients with puerperal fever has been demonstrated.[1] A comparison of the toxin with that produced by the specific *Streptococcus hemolyticus* of scarlet fever [2] by means of the skin test [3] was considered of interest.

The pathologic condition in puerperal fever produced by *Streptococcus hemolyticus* is the same as that of any hemolytic streptococcus infection elsewhere in the body. Thus, the various strains of the streptococcus, as those of erysipelas, scarlet fever or any septic focus, may produce the same picture, except in the case of the scarlet fever strain, which may also produce a scarlatinal rash. This similarity of pathologic pictures was

Leukoderma colli occurring in the late secondary or early tertiary period of syphilis is by no means a rarity. In some cases, isolated areas of leukoderma appear on more distant parts of the body, such as the forehead, chest or flanks.

It is our purpose in this paper to cite two cases in which the areas of vitiligo developed at the sites of a preexisting exanthem, and to show that treatment did not influence the lesions and that the smaller leukodermic areas disappeared as the result of repigmentation after treatment had been discontinued.

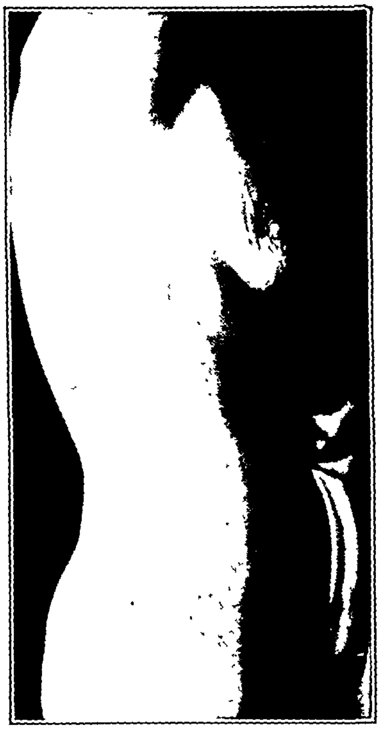

Fig. 2. — Leukoderma one year after development.

In October, 1924, a patient reported at the Baylor Hospital with a chancre on the genitals. The blood Wassermann reaction was 1 plus and the Kahn reaction 3 plus. Skin eruption did not exist. She disappeared from the clinic before a dark field examination was made. Three weeks later she returned, displaying a generalized macular eruption, mucous patches in the mouth, condylomata lata and an unhealed primary lesion. Three months later, there were depigmented macules on areas which were seemingly the sites of the preexisting exanthem. In spite of antisyphilitic treatment the leukodermic areas remained. Now, after about a year, some of the small leukodermic areas on the neck, upper chest and upper back have become repigmented. The repigmentation started at the periphery of the leukodermic areas and gradually encroached on the center. The other lesions have remained stationary, in spite of intensive antisyphilitic treatment.

In April, 1925, the daughter of this patient appeared at the clinic with a macular syphilitic rash, mucous patches in the mouth, and other signs of secondary syphilis. Macules in this case were ringed with mercurochrome-220 soluble. At the end of one week many of the pink macules had become depigmented. This shows how rapidly the areas of leukoderma can develop. At the end of three weeks every macule surrounded by mercurochrome had become depigmented, the areas of vitiligo exactly corresponding to the erythematous macules of the roseola.

SUMMARY

Three patients with a generalized syphilitic macular roseola developed, in the wake of this eruption, generalized macular leukoderma. Depigmented areas developed at the sites of the secondary syphilitic macules in from one to three weeks. The depigmented areas were not influenced by antisyphilitic treatment. The leukodermic areas disappeared as a result of repigmentation, which started at the periphery and gradually reached the center.

ENLARGED TUBERCULOUS TRACHEOBRONCHIAL GLANDS SIMULATING ASTHMA *

M. MURRAY PESHKIN, M.D.
AND
A. H. FINEMAN, M.D.
NEW YORK

Of several hundred children under observation in the asthma clinic the last four years, three were encountered in whom enlarged tuberculous tracheobronchial glands produced symptoms markedly simulating asthma. This condition, judging from the literature, is comparatively infrequent in this country. Because so much attention is being focused on protein hypersensitiveness as an exciting cause of asthma, these cases are likely to be and no doubt are frequently overlooked. This condition is a definite clinical entity and of grave prognostic import. Particularly in large cities with congested immigrant settlements are children prone to develop tuberculous gland infection. According to Schick, these cases are very contagious, and it is therefore important that an early diagnosis be made, so that they can be differentiated from the noncontagious condition of true asthma.

REPORT OF CASES

Case 1.—A. M., a girl, aged 2, referred to the asthma clinic, Sept. 27, 1924, was a full-term baby and one of twins, breastfed and apparently well up to 1½ years of age, when she developed measles followed by bronchopneumonia. At this time, she also contracted an acute right cervical adenitis, which spontaneously subsided after several weeks. After this she developed a cough and wheeze which were almost constant and associated with attacks of dyspnea seemingly asthmatic in character. During the summer of 1924, the cough, wheeze and labored breathing were less severe. This partial relief was attributed by the mother to "sun baths." From the beginning of September, 1924, the symptoms became progressively worse and were without remission. Perspiration was moderate. Occasionally there was a slight fever. There was no history of tonsillectomy likely to be followed by pulmonary complications or aspiration of a foreign body.

The father has been confined to an insane asylum for the past three years. Otherwise, the family history was negative.

When seen at the clinic for the first time, the child appeared in great distress. She wheezed considerably, was markedly dyspneic, and at first appearance seemed to be suffering with a severe attack of asthma. The musical sounds emanating from the chest could be heard at some distance. She was well nourished. The tonsils were moderately enlarged, and the throat was congested. There was a peculiar expiratory dyspnea which is characteristic of this condition. The chest was emphysematous, with the breath sounds diminished at the left base. Numerous rhonchi and sibilant and sonorous râles were heard throughout both lungs. The heart sounds were not easily heard because of the loud wheezing. The lower border of the liver was felt 4 cm. below the costal margin.

A subcutaneous injection of epinephrine hydrochloride (1:1,000) was administered and repeated at short intervals without relief. The Pirquet test was moderately positive. Repeated blood counts were relatively normal. The calcium

---

* From the Children's Asthma Clinic, Mount Sinai Hospital.

first observed by Semmelweis in the necropsy of his friend Kolletschka, who died from a septic infection in his finger incurred during a postmortem, and in the large number of necropsies of the then frequently infected puerpera. Therefore, it was first determined by the Dicks'[4] method that the strain of *Streptococcus hemolyticus* from puerperal fever was not one of the scarlet fever strains.

The scarlet fever toxin was kindly given by the Dicks, already prepared for skin tests. The puerperal fever toxin was a 1 : 1,000 dilution. One tenth cubic centimeter of each toxin was separately injected intracutaneously into each forearm of the patients. The reactions were observed twenty-four hours later. The results of these observations are given in detail in the accompanying table.

ANALYSIS OF RESULTS IN TWO HUNDRED AND FORTY-SEVEN WOMEN

The low incidence of scarlet fever from the history of the pregnant and puerperal women is probably due to inherent immunity in this type of patient (at the Cook County Hospital) or to only slight attacks of scarlet fever which, though sufficient to immunize, were not severe enough to be noticed. The history of puerperal fever would have been of no value, as many organisms as well as different strains of streptococci may cause it. Again, the low incidence of positive Dick and puerperal toxin reactions can be explained by the natural immunity of the patients. The reactions of the two toxins in the same persons would indicate that a person may be immune to one strain of *Streptococcus hemolyticus* but not to another. Only in a few patients did a positive Dick reaction occur when those patients had a history of scarlet fever (less than 1 per cent). The positive skin reactions to the puerperal toxin used indicate the susceptibility of these patients to this strain of streptococcus, while there may be a greater or lesser number of positive reactions to other strains.

Bacterial Pollution and Natural Purification of Rivers.—Extended observations of the pollution of Illinois and Ohio rivers have indicated that the numbers of bacteria contributed per capita by the sewered populations of various cities are reasonably constant; these numbers change, however, with seasonal temperature, being much greater in summer than in winter. Such bacteria tend to increase in numbers in the receiving stream for a short period and then decrease at orderly rates as the time from the point of maximum density is increased. These rates of decrease were found to be affected by water temperature and apparently by concentration, being most intensive during the warmer months and under conditions in which the density of bacteria was greatest. Having established definite quantitative relationships from these observations, and assuming that they are fairly representative of stream conditions in general, a method is suggested for estimating the maximum concentration of *B. coli* in streams of known volume of flow that may be expected to result from pollution contributed by known sewered populations. Furthermore, the concentration of such organisms remaining at any point downstream may be estimated, provided the velocity of flow is ascertained. If the observations are representative of general biologic laws, they are of practical value for estimating the increasing burden placed on streams receiving the sewage of growing communities and, consequently, the added loads that water-purification plants must be prepared to handle where such polluted water courses are used as sources of water supply.—Hoskins, J. K.: *Pub. Health Rep.* **41**:330 (Feb. 19) 1926.

LEUKODERMA SYPHILITICUM *

BEDFORD SHELMIRE, M.D.
AND
THOMAS J. CALHOUN, M.D.
DALLAS, TEXAS

Hardy,[1] in 1853, under the designation of "syphilide pigmentaire du col" was the first to describe leukoderma colli. This type of syphilitic vitiligo has since been described by many syphilographers. It occurs most frequently in the sixth to the twelfth month after infection but may appear much later. Those affected are usually women under 35 years, the sites of predilection being the neck and adjoining cutaneous surfaces. The lesions are either discrete or confluent depigmented macules, round, oval or irregular, and from 0.5 to 1.5 cm. in diameter or larger. If discrete, they are separated by areas of normal or hyperpigmented skin. This gives the neck a peculiar mottled appearance, in accordance with the old description of a neck that has been sunburned through lace.

Various theories for the production of these lesions have been advanced. Some assert that the dark areas, others that the light areas, are on the sites of earlier syphilitic lesions. Some German authors regard the disorder as a syphilitic leukoderma on the site of a previous roseola. Fox[2] considers it of syphilitic origin but not a direct manifestation of syphilis. Duhring[3] states that it is a pigmentary phenomenon, probably not differing from chloasma. Freymann,[4] from a large number of cases of leukoderma in acquired syphilis, believes that it does not follow an exanthem but rather evidences a disease of central nervous origin which influences pigment distribution. It is probable that two distinct entities exist, one characterized by a depigmentation and the other by a hyperpigmentation. These may occur singly or together.

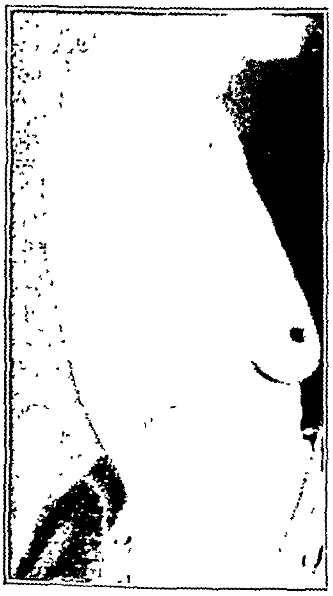

Fig. 1.—Appearance of leukoderma at time of development.

Leukoderma colli comes on insidiously, unknown to the patient, does not progress, and is recalcitrant to antisyphilitic treatment. Goodman[5] says, "Despite an extremely broad opportunity afforded me for observation of active cutaneous syphilitic patients in the primary and secondary periods of the disease, I have never been able to determine the beginning or end of leukoderma."

[5] Goodman, Herman: The Collar of Venus: Melanoleukoderma Colli of Syphilis, J. A. M. A. **82**: 701 (March 1) 1924.

Leukoderma colli occurring in the late secondary or early tertiary period of syphilis is by no means a rarity. In some cases, isolated areas of leukoderma appear on more distant parts of the body, such as the forehead, chest or flanks.

It is our purpose in this paper to cite two cases in which the areas of vitiligo developed at the sites of a preexisting exanthem, and to show that treatment did not influence the lesions and that the smaller leukodermic areas disappeared as the result of repigmentation after treatment had been discontinued.

In October, 1924, a patient reported at the Baylor Hospital with a chancre on the genitals. The blood Wassermann reaction was 1 plus and the Kahn reaction 3 plus. Skin eruption did not exist. She disappeared from the clinic before a dark field examination was made. Three weeks later she returned, displaying a generalized macular eruption, mucous patches in the mouth, condylomata lata and an unhealed primary lesion. Three months later, there were depigmented macules on areas which were seemingly the sites of the preexisting exanthem. In spite of antisyphilitic treatment the leukodermic areas remained. Now, after about a year, some of the small leukodermic areas on the neck, upper chest and upper back have become repigmented. The repigmentation started at the periphery of the leukodermic areas and gradually encroached on the center. The other lesions have remained stationary, in spite of intensive antisyphilitic treatment.

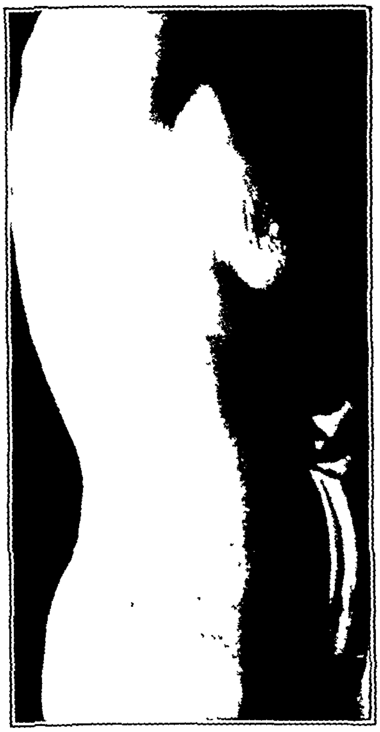

Fig. 2.—Leukoderma one year after development.

In April, 1925, the daughter of this patient appeared at the clinic with a macular syphilitic rash, mucous patches in the mouth, and other signs of secondary syphilis. Macules in this case were ringed with mercurochrome-220 soluble. At the end of one week many of the pink macules had become depigmented. This shows how rapidly the areas of leukoderma can develop. At the end of three weeks every macule surrounded by mercurochrome had become depigmented, the areas of vitiligo exactly corresponding to the erythematous macules of the roseola.

SUMMARY

Three patients with a generalized syphilitic macular roseola developed, in the wake of this eruption, generalized macular leukoderma. Depigmented areas developed at the sites of the secondary syphilitic macules in from one to three weeks. The depigmented areas were not influenced by antisyphilitic treatment. The leukodermic areas disappeared as a result of repigmentation, which started at the periphery and gradually reached the center.

ENLARGED TUBERCULOUS TRACHEOBRONCHIAL GLANDS SIMULATING ASTHMA *

M. MURRAY PESHKIN, M.D.
AND
A. H. FINEMAN, M.D.
NEW YORK

Of several hundred children under observation in the asthma clinic the last four years, three were encountered in whom enlarged tuberculous tracheobronchial glands produced symptoms markedly simulating asthma. This condition, judging from the literature, is comparatively infrequent in this country. Because so much attention is being focused on protein hypersensitiveness as an exciting cause of asthma, these cases are likely to be and no doubt are frequently overlooked. This condition is a definite clinical entity and of grave prognostic import. Particularly in large cities with congested immigrant settlements are children prone to develop tuberculous gland infection. According to Schick, these cases are very contagious, and it is therefore important that an early diagnosis be made, so that they can be differentiated from the noncontagious condition of true asthma.

REPORT OF CASES

Case 1.—A. M., a girl, aged 2, referred to the asthma clinic, Sept. 27, 1924, was a full-term baby and one of twins, breastfed and apparently well up to 1½ years of age, when she developed measles followed by bronchopneumonia. At this time, she also contracted an acute right cervical adenitis, which spontaneously subsided after several weeks. After this she developed a cough and wheeze which were almost constant and associated with attacks of dyspnea seemingly asthmatic in character. During the summer of 1924, the cough, wheeze and labored breathing were less severe. This partial relief was attributed by the mother to "sun baths." From the beginning of September, 1924, the symptoms became progressively worse and were without remission. Perspiration was moderate. Occasionally there was a slight fever. There was no history of tonsillectomy likely to be followed by pulmonary complications or aspiration of a foreign body.

The father has been confined to an insane asylum for the past three years. Otherwise, the family history was negative.

When seen at the clinic for the first time, the child appeared in great distress. She wheezed considerably, was markedly dyspneic, and at first appearance seemed to be suffering with a severe attack of asthma. The musical sounds emanating from the chest could be heard at some distance. She was well nourished. The tonsils were moderately enlarged, and the throat was congested. There was a peculiar expiratory dyspnea which is characteristic of this condition. The chest was emphysematous, with the breath sounds diminished at the left base. Numerous rhonchi and sibilant and sonorous râles were heard throughout both lungs. The heart sounds were not easily heard because of the loud wheezing. The lower border of the liver was felt 4 cm. below the costal margin.

A subcutaneous injection of epinephrine hydrochloride (1:1,000) was administered and repeated at short intervals without relief. The Pirquet test was moderately positive. Repeated blood counts were relatively normal. The calcium

---

* From the Children's Asthma Clinic, Mount Sinai Hospital.

content of the blood was 9 mg. per hundred cubic centimeters. The urine was normal. The protein skin tests were negative.

Roentgenoscopy of the chest, Oct. 3, 1924, showed especially large right hilum shadows, with a marked emphysema of the entire left lung. The left side of the diaphragm was depressed, and the heart and mediastinum were pushed over to the opposite side. There was also an infiltration in the left lower lobe (fig. 1). The child was admitted to the hospital because she was suffering with an unusual degree of respiratory embarrassment, being practically in a "status asthmaticus." Nothing especial was done for the child except hospitalization. October 14, the roentgenogram showed a restored position of the mediastinum and the heart, with beginning resolution of the infiltration at the left lower lobe (fig. 2), and, October 25, the infiltration showed almost complete resolution with a diminution of the hilum shadows.

The child was discharged from the hospital much improved, a spontaneous resolution evidently having taken place to a large extent. It was suggested to the mother that the child be sent to a preventorium, so that proper treatment could be instituted. The mother, however, refused to accept our diagnosis of the child's condition and took her to another institution, where she was treated for asthma. Subsequently, the child was traced to a day nursery, which she had been attending for the past eight months. We were informed that the attending physician of the nursery considered the case "asthmatic bronchitis." However, Nov. 12, 1925, one of us (A. H. F.) visited the patient's home, and an examination of the chest failed to show any evidence of wheezing or dyspnea. The mother stated that the child wheezed only occasionally, and refused to submit her to further roentgenoscopic examination.

Case 2.—R. S., a boy, aged 4 months, an only child, full-term and breast-fed, referred to the clinic, April 28, 1925, with a diagnosis of asthma, had apparently been well up to 3 months of age, when he began to cough and wheeze. At this time, an eczema appeared on the face. There was no history of a preceding upper respiratory infection. The "asthmatic condition," while varying somewhat in degree since its onset, was nevertheless continuous. The infant perspired freely, but had no fever. In spite of the constant cough, wheeze and dyspnea, he seemed well nourished. The family history was negative. However, the mother gave a history of a cough lasting several months. The baby when first seen was extremely dyspneic, wheezed considerably and had the characteristic expiratory dyspnea together with numerous musical sounds in the chest, which were heard at some distance. There were many rhonchi, and sibilant and sonorous râles, but no areas of dulness in the lungs. The spleen was palpated 3 cm. below the costal margin. Dry eczematous patches were seen on the left cheek.

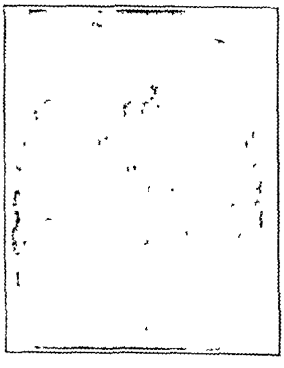

Fig. 1 (case 1).—Especially large right hilum shadows with marked emphysema of the entire left lung, Oct. 3, 1924. The left side of the diaphragm is depressed, and the heart and mediastinum pushed over to the opposite side. There is also an infiltration in the lower left lung.

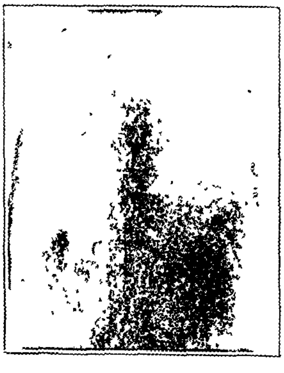

Fig. 2 (case 1).—Large right hilum shadows with a marked emphysema of the entire left lung, a restored position of the mediastinum and heart with beginning resolution of the infiltration at the lower left lobe, Oct. 4, 1924.

The Pirquet test was strongly positive, and the protein skin tests were negative. April 29, roentgenoscopy of the chest showed a marked enlargement of the bronchial glands at the roots of both lungs. The infant was not hospitalized. May 12, roentgenograms showed, in addition to the foregoing finding, an infiltration at the right base (fig. 3). May 21, there were large hilum shadows, a marked overdistention of the right lung with displacement of the right side of the diaphragm downward, and marked displacement of the heart to the left (fig. 4).

The administration of epinephrine hydrochloride (1:1,000) had no effect. The wheezing, cough and dyspnea were persistent. The parents would not consent to have the child sent away to the country, and when she was seen seven months later, her condition remained practically unchanged.

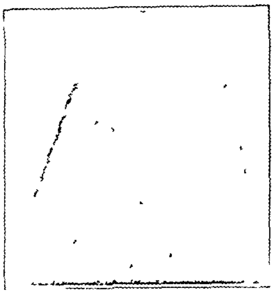

Fig. 3 (case 2).—Marked enlargement of the bronchial glands at the root of the right lung, with an infiltration at the right base, May 12, 1925.

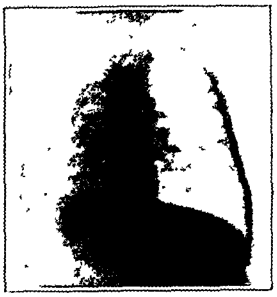

Fig. 4 (case 2).—Large hilum shadows, a marked overdistention of the right lung with displacement of the right side of the diaphragm downward and marked displacement of the heart to the left, May 21, 1925.

This case is similar to the previous one, except that the child was much younger, and roentgenograms showed the early stages of the disease.

Case 3.—J. G., a girl, aged 6 months, full-term and bottle fed, referred to the hospital, Jan. 7, 1926, was apparently well up to 4 months of age, when she commenced to cough and wheeze. These symptoms became progressively worse, and were constant from the onset. Perspiration was absent. Occasionally she had a slight fever. The mother has pulmonary tuberculosis and is living at home. This condition was first diagnosed in November, 1925.

When seen, the infant presented the characteristic expiratory dyspnea. The cough was high pitched. She was fairly well nourished. There were papular necrotic tuberculids on the back of the neck, chest and thighs, measuring from 1 to 3 mm in diameter. The tonsils were small. There were numerous musical râles in both lungs. The resonance was decreased and the breath sounds diminished over the entire right lung, with the exception of the upper lobe posteriorly, where the sounds were of tubular character, such as are heard in cases with bronchial stenosis. The heart was slightly displaced to the left. The lower border of the liver was felt 3 cm below the costal margin.

The Pirquet test was positive. The blood count was relatively normal. The urine was normal. Roentgenoscopy of the chest, Jan. 9, 1926, showed scattered infiltrations throughout the right upper and lower lobes. The bronchial lymph nodes at the right hilum were enlarged. There was a circular shadow, 2.5 cm. in diameter, in the right upper lobe, which had the appearance of a cavity. The heart was displaced to the left (fig. 5).

One month later the child was still in the hospital; her condition remained unchanged.

CHARACTERISTICS OF THE CONDITION

On the basis of these three cases and of reports in the literature, we find that this condition is confined largely to infants and young children. The usual history is that during the first year of life the child gradually begins to wheeze. These symptoms persist with no relief or remission. The mother is informed that the child has asthma but cannot understand why the baby does not improve. There may be a low grade fever, vomiting and perspiration, which may continue for one year or more.

The infant presents a pinched appearance. The alae nasi overact. Respiration is greatly embarrassed. The distress is greater than that seen in the average asthmatic child. An expiratory dyspnea suggestive of bronchial obstruction is characteristic.

There are numerous rhonchi, and loud sibilant and sonorous râles throughout both lungs like a human music box. These can be heard throughout the room. The breath sounds are usually diminished on one side, where there may be a hyperresonant note suggestive of unilateral emphysema. This finding is of diagnostic importance. There may be dulness at one of the bases. The spleen and liver are often enlarged. A rhythmic motion of the head occurring in extreme cases is mentioned by Bougarel, Schick and Finkelstein.

The subcutaneous injection of epinephrine hydrochloride (1:1,000) even in repeated doses does not offer relief. The Pirquet test is always positive and can readily be confirmed by the Mantoux test. A positive tuberculin reaction in an infant or child of from 1 to 2 years of age with a persistent wheeze is very significant. It immediately suggests enlarged tuberculous tracheobronchial glands. Roentgenoscopy of the chest will confirm the diagnosis.

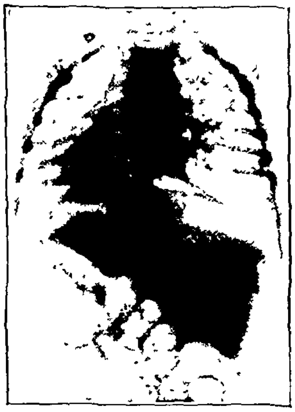

Fig. 5 (case 3).—Scattered infiltrations throughout the right upper and lower lobes, Jan. 9, 1926. The bronchial lymph nodes at the right hilum are enlarged. There is a circular shadow 2.5 cm. in diameter in the right upper lobe, which has the appearance of a cavity. The heart is displaced to the left.

The roentgenogram shows wide irregular shadows at the hilum, which are interpreted as masses of enlarged tracheobronchial glands. These hilum shadows are enormous for a child of 1 or 2 years. There may be a larger group of glands on one side than on the other, with a resultant unilateral emphysema and depression of the diaphragm of the same side due to pressure on a stem bronchus. The mediastinum and heart may be pushed over to the opposite side. Infiltrations at the base are common.

LITERATURE

In 1910, Schick[1] published a paper which for the first time placed this subject on a definite clinical basis. He noted that in 1904, Variot, Bruder and Guinon were the first to observe this expiratory type of dyspnea associated with enlarged bronchial glands; and that in 1907 Bougarel reported ten cases, most of which were collected from the literature. Schick maintained that in infancy and early childhood the occurrence of expiratory dyspnea and wheezing were diagnostically significant of tuberculous hilum glandular enlargement. The positive tuberculin skin reaction and roentgen-ray findings corroborated the diagnosis. Of his thirty-six cases presenting this clinical picture, the diagnosis in thirteen was confirmed by necropsy. In the great majority of his cases, symptoms appeared before 1 year of age.

Sluka[2] reported the roentgen-ray findings in Schick's cases. Besides hilum shadows, he observed that pulmonary infiltrations in the upper lobe occurred almost exclusively in infants.

Eckert[3] cited a case in a young child, with interesting necropsy findings. Rach[4] reported one case. Marfan[5] reported on a few infants who displayed an expiratory roaring sound or stridor due to compression of the trachea or bronchi by enlarged tuberculous mediastinal glands. Finkelstein[6] reported an extreme case in a 5-months baby. Cameron[7] stated that pressure on the trachea or bronchi from tuberculous mediastinal glands may closely simulate bronchial asthma, but cited no cases. Koch[8] quoted Schick's paper at length. Wallgren[9] recently reported three cases in which typical asthmatic attacks developed during a period when signs of bronchial compression were present.

It is surprising to note that the American literature, which is prolific on the subject of asthma, contains so few references to this condition. Abt,[10] in an article on asthma in children, cited no cases of this variety but stated that "enlarged bronchial glands may give rise to severe dyspnea which may simulate asthma." Sauer[11] discussed the diagnosis, while Stoll[12] emphasized the value of the roentgen-ray findings in this condition. Fishberg,[13] in discussing the roentgenogram, declared that "it is hazardous to diagnosticate tracheobronchial adenopathy because of these opacities, when the clinical picture is not in agreement." Pierson[14] discussed the interrelationship of asthma and glandular tuberculosis in older children, but cited no cases of infants or young children. Koessler[15] stated that in the past fifteen years he had seen twelve children with enlarged tracheobronchial glands presenting symptoms simulating asthma. Most of his cases occurred in children over 2 years of age, and only a few of them had tuberculous glands. Ratner[16] reported four cases of pulmonary tuberculosis in infants, in which the enlarged bronchial glands caused marked asthmatic breathing.

DIFFERENTIAL DIAGNOSIS

1. Tuberculous tracheobronchial lymph nodes sufficiently large to cause symptoms simulating asthma occur most frequently before the second year. During

16. Ratner, Bret: Pulmonary Tuberculosis in Early Infancy Simulating Bronchial Asthma, M. Clin. N. America **9**: 826 (Nov.) 1925.

the period of bronchial compression, wheezing is constant. The expiratory dyspnea is characteristic and is not relieved by subcutaneous injections of epinephrine hydrochloride (1:1,000). The positive tuberculin reaction along with the roentgenoscopic chest findings confirms the clinical diagnosis.

2. Bronchial asthma—protein sensitive and nonprotein sensitive—occurs most commonly in children, with the age of onset after 2 years. Before 2 years, the tuberculin skin reaction is usually negative. The asthmatic symptoms are never constant, and are always relieved by the administration of epinephrine hydrochloride. Roentgenoscopy of the chest fails to show the characteristic findings seen in cases of "expiratory dyspnea."

3. Asthma in older children in whom enlarged hilum shadows are found must show exceedingly large glands, which probably are not actively tuberculous, before it can induce symptoms.

4. Children with "thymic asthma" can often be recognized by their general appearance, by the presence of parasternal dulness and by the shadows seen in the roentgenogram.

5. The symptoms manifest during the first days of pneumonia may sometimes resemble this condition. Congenital stridor, laryngeal diphtheria and miliary tuberculosis can usually be differentiated.

6. Spasmophilia in children may be associated with attacks of asthma. These attacks, first described as bronchotetany by Lederer,[17] may occur as an independent manifestation or along with other symptoms of this constitutional disturbance, such as laryngismus stridulus, positive Chvostek sign, an increased electrical excitability, and a decrease in the calcium content of the blood.

7. A foreign body in a bronchus may closely resemble "expiratory dyspnea." However, the "asthmatoid wheeze" during expiration, with impaired resonance, diminution of breath sounds and the presence of many râles on one side of the chest while the other side is relatively normal, suggests the diagnosis of a foreign body in a stem bronchus. The roentgenogram may outline the foreign body. If it is in the trachea, a snapping sound is heard at the mouth during cough, and a thud or impulse striking against the subglottic narrowing may be felt over the trachea.[18]

COMMENT

The explanation offered by Schick [1] for the various symptoms associated with enlarged tuberculous glands was founded on an anatomic basis. From the necropsy findings in such cases, he deduced that the enlarged glands exerted pressure at the bifurcation of the trachea or on the main bronchus. There was usually more compression on one side than on the other. This contention was supported by Guinon,[19] Eckert,[3] Rach [4] and others. Jumon [20] causually mentioned Landouzy's theory, which held that the symptoms were due to circulatory poisons liberated by the tubercle bacilli. Pierson [14] stated the possibility of the split products of the tubercle bacilli inducing a state of anaphylaxis. Finally, Hoover [21] and Wallgren [9] attributed the symptoms to irritation of the vagus nerve.

It seems that the most plausible explanation for this condition is the mechanical obstruction theory advanced by Schick.

The prognosis is usually poor in such cases, unless the children can be put under extremely favorable conditions or confined to a preventorium. The fact that they are liable to infect other infants and children warrants their isolation. The importance of an early diagnosis is therefore obvious. Of the thirty-six cases reported by Schick, twenty-two children died in early childhood, and seven who were sent away to the country were doing well for over two years. Healing of the glands may take place under suitable hygenic environment. Mercury quartz lamp or roentgen-ray therapy may prove of value.

That enlarged tuberculous tracheobronchial glands inducing symptoms simulating asthma are more common in infants and young children than one is led to believe from the reports in the American literature seems evident. Probably some cases are not recognized as such and the patients are included among the general group of asthmatic children.

THE TREATMENT OF DEEP ROENTGEN-RAY BURNS BY EXCISION AND TISSUE SHIFTING *

JOHN STAIGE DAVIS, M.D.
BALTIMORE

It would be rational to expect that, with the advances made in the knowledge of the proper dosage of roentgen rays, burns from this source would become less and less frequent. As a matter of fact, this does not seem to be the case, as in my own practice I am seeing these burns even more frequently than five years ago, when I [1] presented a paper on the radical treatment of roentgen-ray burns before the American Surgical Association. This report and the papers written since then by Porter and Wolbach,[2] Bevan,[3] E. G. Blair,[4] McArthur [5] and others have apparently had little effect on those who first see and treat the majority of these cases. For this reason, I am again bringing the subject forward, as I feel that it is of sufficient importance to warrant further discussion.

Most of the burns seen today are the result of the therapeutic use of roentgen rays in dermatologic and other clinical conditions. Some follow the prolonged use of the fluoroscope and others are due to overexposures by unskilled operators. To these may be added a group of burns which occur in spite of the most careful exposures administered by skilled roentgenologists.

Fortunately, the methods of protection now known have practically eliminated the danger of chronic burns from the hands of the professional roentgenologist. However, we still see some of the frightful results of the lack of protection from roentgen rays, and this group of cases must also be included.

Most of the burns do not completely change the tissues, and with proper treatment take care of themselves; but now and then deeper tissues are involved and more disastrous consequences follow. All degrees of burns may be produced, from simple erythema up to the destruction of the whole thickness of the skin and varying depths of the underlying tissues. In this paper, I will consider only the deep burns.

CLINICAL PICTURE

It is well to bear in mind that in many instances the depth of the burn varies in different portions of the affected area. The entire area may be depressed somewhat below the normal skin, and is also often tightly adherent to the underlying tissue. The healed portion is hairless and atrophied, sometimes wrinkled, sometimes smooth, and is usually dry and shiny, with or without a blotchy, brownish pigmentation. In the majority of instances, there are characteristic telangiectases, which may be discrete or occur in patches. More or less extensive patches of keratosis are also frequently seen. There are usually one or more chronic ulcers found which may be comparatively superficial or may involve the full thickness of the skin, with a considerable depth of the underlying soft parts. The history of many of these ulcers is that they heal very slowly and then break down again, this process being repeated over and over. However, some of the deep ulcers never heal without operative intervention.

As a rule, there is an irregular shaped patch of tightly adherent yellowish white necrotic tissue occupying the central portion of the ulcer. The ulcer edges are thickened and hard, grayish red and often everted. In fact, the clinical appearance is frequently suggestive of malignancy. From the edges of the ulcer outward to the normal skin, we find more or less infiltration with scar. Occasionally, the entire area is covered with a sharply differentiated brown mummified tissue.

Exquisite sensitiveness is characteristic of the deep burns, regardless of their size. The intense burning, boring pain in the ulcerated area may be due to irritation of nerve endings caused by infection, which is always present; to changes in the nerves themselves caused directly by the rays or by the progressive obliteration of the blood vessels, or to pressure on the nerves by scar. Any one or all of these conditions may exist.

The outline of the involved area where it merges into the normal skin may be quite irregular, and both laterally and vertically is without definite limitation.

While the chief destruction of tissue is ordinarily in the corium and subcutaneous tissues, it is impossible to tell the depth of the destructive process until excision is done, and even then it is sometimes difficult. The tissues are of extreme hardness and will often turn the edge of a scalpel. The subcutaneous fat may be completely destroyed, but if present is deep yellow, and very firm and resistant, because of scar tissue involvement. In deep burns, the muscle may be entirely replaced by dense scar tissue, or there may be varying degrees of infiltration with scar. There may be marked necrosis of the underlying bone.

I will quote again the report sent me by Dr. J. C. Bloodgood, which is based on a microscopic study of the excised tissues from deep roentgen-ray burns: "The characteristic features in an x-ray burn as compared to a leg ulcer, or any other type of simple ulcer are: x-ray keratosis at the edge of the ulcer with atypical downgrowth of epithelium with or without pearly body formation; a very superficial zone of cellular granulation tissue; unusual scar tissue formation, which, as a rule, extends to the muscle; thickening of the walls of the blood vessels with endothelial obliteration, and minute abscess formation beneath the surface of the ulcer." The lymphatics are obliterated. The hair follicles are destroyed, as are also the sweat and sebaceous glands.

TREATMENT

When a patient with a deep ulcerated roentgen-ray burn applies for help, what is the best method of treatment? Should we continue local applications, with the addition of rays of various kinds, or should we resort to radical surgical measures? To my mind, the problem seems essentially surgical.

The burns that come to me are usually of long duration, and are those on which everything has been tried unsuccessfully. In the last two or three years, I have found that in almost every one of the severe cases ultraviolet rays have been used, and a cure has been promised each time. Sometimes radium has been used and often both ultraviolet rays and radium, in addition to a great variety of local applications. Occasionally, even more roentgen rays have been tried. I must confess that I cannot fathom the reasoning used for employing other rays to restore tissues that are already completely changed or destroyed by the original ray burn, even though these rays may be the complements of the rays causing the burn.

It is possible that ultraviolet rays and radium may be of value in the treatment of roentgen-ray burns in which the tissues have not been completely changed, but in the deep burns of long standing my experience has been that the condition is aggravated by these rays, and that time is wasted by this treatment.

As a matter of fact, I have not seen an instance among the cases referred to me in which any really deep burn caused by roentgen rays has been cured by radium or ultraviolet rays, and feel that there is little likelihood of a cure, unless perhaps the condition becomes so intensified by further radiation and additional burning that finally the entire area sloughs out, after which healing by granulation may follow. My point of view on this subject may be warped, as I usually see only the severe cases and the failures, but it is based on the results of a fairly wide experience with the patients who have been thus unsuccessfully treated elsewhere, and who as a last resort have been sent to me for a final trial of radical measures. Many of these patients, having suffered intensely over a long period of time, object when operative treatment is suggested, as they think it means increased pain with little prospect of improvement. This idea is fostered to a large extent by those who are uninformed and by the advocates of the various rays, who usually rather foolishly promise a cure and oppose radical treatment. It is an interesting fact that a considerable percentage of these patients have been physicians.

I am convinced that, when a deep burn has become definitely established and the ordinary local methods (even including ultraviolet rays, etc.) have been tried for a reasonable time without success, excision with tissue shifting is the method of choice—in fact, is the only method promising relief from the actual lesion as well as from the danger of subsequent malignant degeneration. I cannot speak too strongly on this subject, as I see each year a number of physical wrecks caused by the long continued improper treatment of these burns.

A case in point occurred in a colleague who was unfortunate enough to be severely burned several years ago by roentgen rays while being treated for pruritus ani. He was practically incapacitated, and suffered horribly and continuously. He tried every method suggested, ultraviolet rays, radium and nearly all kinds of local applications, without success. Finally, operative treatment was urged, and as he was bitterly opposed to such treatment, he was led to correspond with dermatologists, physiotherapists and others interested in the subject, both in this country and abroad. With the exception of a comparatively few men who advocated excision, they advised him to continue these palliative treatments and shun operation. Finally, having reached the end of his endurance, he asked for operative treatment, and within six weeks was out of the hospital, healed and free from pain. I could cite patient after patient whose story is comparable to this one.

METHOD

General anesthesia is usually necessary in these cases, as many of the patients are in a highly nervous, depleted condition and cannot stand additional pain and manipulation.

In the ideal case, the ulcer and the surrounding area of induration should be excised, out to and down to healthy tissue; in other words, with a good margin. In many instances, however, complete excision either outward or downward is impossible on account of the extent and situation of the burn, but in these cases the excision should be as radical as circumstances will permit.

Occasionally, I felt justified in grafting immediately, when the exposed tissues seem normal and the excision has been complete; but in the majority of instances following the excision of deep old burns, there is a general oozing which is almost impossible to check. It is obvious, therefore, that on such a wound immediate grafting would be futile. In these cases, I cover the wound with perforated cellosilk or with gauze impregnated with a 3 per cent bismuth tribromphenate (xeroform) ointment and then pack the depression snugly with sterile sea sponges, which are secured under pressure.

After forty-eight hours, the dressings may be removed without pain and without causing bleeding. In the course of a few days, following the continuous application of compresses saturated with physiologic sodium chloride solution, the granulations usually sprout and are soon ready for grafting. Gauze saturated with balsam of Peru, 1 part, and castor oil, 3 parts, is also useful for stimulating granulations. The type of graft used either for immediate grafting or after granulations have formed should depend on the location of the lesion. My own preference in the greater number of these cases requiring grafting is for "small deep grafts," and I find that they give very satisfactory results. I occasionally use Ollier-Thiersch grafts, but when large grafts are indicated I prefer those of whole thickness, especially in exposed situations. All of these delayed grafts are placed on the flat healthy undisturbed granulations. In a number of instances, I have used pedunculated flaps from neighboring tissues which have not been changed by the rays, or from a distant part, and have found them of great use when a pad of fat, in addition to whole thickness skin, was necessary. In fact, in exposed positions this is the most desirable procedure.

The flap may be shifted on to the fresh wound immediately after excision of the burned area, if conditions are favorable; but if the shifting is delayed, I find that the results are better if the granulating area is removed before the flap is sutured into its new bed. As the integrity of the circulation of the flap is particularly important in these cases, some method of delayed transfer is advisable.

When the burn is comparatively small and in a favorable position, it is often possible to excise it completely, using an elongated elliptic incision, and then to close the skin by sutures after undercutting.

Occasionally, we see an extensive thick scar of an old deeply burned area, which is fairly movable over the underlying tissues, but is unsightly and uncomfortable and breaks down frequently. In certain situations, it is advisable to treat such an area by gradual partial excision with closure, allowing the surrounding skin to stretch slowly, rather than to excise the entire area at one operation and fill the defect with grafts or a flap. By this method, the whole area can often be removed, and the final result is a comparatively inconspicuous scar.

Massage should be started on the grafts and flaps about three weeks after healing has taken place, and should be continued for several months.

COMMENT

The susceptibility of the skin of certain individuals to roentgen rays is a matter that must be considered, and as far as I know there is no method of telling who is hypersensitive and who is not. In a general way, this may be likened to the effect of the sun on different skins, as with the same exposure at the same time, one skin will be badly blistered and another only reddened or tanned.

I would emphasize that there is definite danger in the clinical use of all kinds of rays, and in my opinion, which is based largely on the observation of untoward results, these agencies should be used with the greatest caution and only by competent operators. Severe burns sometimes follow single exposures, but are more frequently caused by multiple exposures. My series of deep burns includes lesions in practically every region of the body. Their duration has been from a few weeks to many years. A peculiarity of roentgen-ray burns is that weeks, months or even years may elapse before the extent of the injury done becomes apparent.

The reason for this long period of latency is well explained by Matas,[6] who says that "the underlying pathology of these long delayed and necrogenic x-ray burns is a progressive proliferative endarteritis which obliterates the arterioles of the derm and subdermal connective tissue, leading to a gradual but fatal ischemia and nutritional disturbances in the radiated field."

Roentgen-ray burns often cause complete loss of function of a part. In more severe burns of the hands and feet, one is struck by the rigidity of the fingers and toes due to involvement of the tendons and overlying soft parts, and even of the joints and bones.

In those instances in which tendons have been destroyed and there is little injury to the bones, it is advisable to fill the defect with a pedunculated flap of skin and fat, and later to restore the tendon by the method best suited to the particular case.

---

[6] Matas, Rudolph: Remarks on the Delayed or Remote Appearance of X-Ray Burns After Long Periods of Latency, Am. J. Roentgenol. **13**: 37 (Jan.) 1925.

The general loss of function is very marked, and a patient with even a comparatively small burn, wherever situated, is often almost completely incapacitated. This means, of course, lack of ability to earn a living, which to many is a very serious consideration.

The use of narcotices of one kind or another by many of these patients is necessary to control the severe pain that is usually present, and in a short time the morale is broken, and we have two problems on our hands instead of one.

When large areas are involved, we seldom excise sufficient tissue, and infection sometimes occurs in the nonresistant margins of these wounds. Occasionally, there is sloughing of the entire margin of the wound, although the excision had been apparently complete, and this reason alone would make it advisable to defer grafting, or the transference of a flap. Unless the operative intervention is radical, that is, unless the burned area is excised as widely and as deeply as necessary, this method of treatment is not completely effective, and subsequent secondary operations may be needed. In some instances, years may elapse before the secondary operations become necessary.

The excision of the burned area can be done either with a scalpel or with a cautery knife. I prefer to use the scalpel in the majority of cases, because the changed tissues can be recognized more readily; immediate skin grafting or flap shifting may be possible, and if this is not done the granulations cover the defect more promptly. When the cautery knife is used, hemorrhage is often lessened or checked, but immediate grafting is impossible on account of the searing of the tissues; also, the cauterized tissues must be thrown off before granulations are ready for grafting.

Fulminating infections sometimes occur in areas of skin that have been deeply burned by roentgen rays. Prompt excision with a generous margin is indicated, or even amputation of the part may be necessary to control the rapid spread of the infection. Amputation is also sometimes expedient in the extremities when there is no hope of saving the part by excision and tissue shifting or when malignant degeneration has taken place.

Periarterial sympathectomy might be useful in selected cases in the treatment of ulcerated deep roentgen-ray burns, especially in checking pain. I have had no experience with this method for this purpose, but feel that more direct local measures are preferable.

It has been said that the pain of areas burned by roentgen rays is due to infection and that this infection with the pain can be eliminated by two or three exposures to ultraviolet rays. This, unfortunately, as far as pain is concerned, has not been the result in any of the patients that have come to me after such treatment, as the pain has persisted and in some instances has been aggravated. Sometimes, when there has been a deep burn in which healing has finally taken place after many months, the scar may also be very painful. As there is no question of infection in these cases, the pain is probably due to nerve changes caused by the obliterative processes in the blood vessels of the corium and subcutaneous tissues, by the direct action of the rays on the nerves, or to pressure by scar tissue, or to all these conditions. In these cases, systematic massage should first be used, if no areas suggesting malignancy are present; if this is ineffective, then excision with the shifting in of a flap or grafting should be considered.

In the majority of instances, we can promise that with the excision of the burned area, the characteristic pain will usually cease permanently. If nothing else was accomplished, this alone would make it well worth while. Division of nerves leading to the area will also relieve the pain.

The tendency to malignant degeneration in chronic roentgen-ray burns is interesting and important. Porter,[7] who has had a very wide experience with such burns, finds that cancer rarely develops in lesions resulting from a single massive dose or a few exposures at short intervals; it occurs more frequently in burns in which there have been many exposures over a long period of time, as in the treatment of psoriasis, eczema, lupus and malignant diseases, and most frequently in those cases in which varying degrees of chronic roentgen-ray dermatitis had been present for many years, as typified by the lesions on the hands of the pioneer roentgenologists.

My experience practically coincides with Dr. Porter's. In a general way, I have found that when there has been destruction of the whole thickness of the skin and often of the underlying tissues with slough *en masse* and deep ulceration, there is no more likelihood of malignant degeneration than in any other very chronic ulcer. On the other hand, ulceration of a patch of keratosis or the breaking down of areas of chronic dermatitis should be viewed with suspicion.

When malignancy is shown by frozen section of the excised ulcer, removal of the lymph glands into which the part drains is indicated, and in certain instances even more radical measures may be necessary. In order to avoid possible malignant degeneration of patches of keratosis, it is advisable to destroy these areas as soon as possible after their appearance. My own preference is for excision with closure or with grafting; but the method used in these early cases is immaterial so long as the keratosis is removed, and a lasting healing results.

Quite frequently we have a deep burn following the treatment of a superficial malignant growth without the growth itself having been completely destroyed. In these cases, excision of the entire area with the cautery is advisable.

Excision with tissue shifting is also the procedure of choice in chronic deep radium burns, of which I have had a considerable number, and ultraviolet ray burns, and promises a quicker and better result than any other method.

CONCLUSIONS

When a deep roentgen-ray burn occurs and the ordinary local methods have been tried for a reasonable time, nothing is gained by delaying operative work.[8] In none of the cases referred to me has treatment with ultraviolet rays and other rays been beneficial. Early excision of deep burns with tissue shifting promises more surely than any other method yet devised a reasonable prospect of permanent relief in a comparatively short time.

Pain is eliminated and, in many instances, function is restored, and patients who have been incapacitated for years have been returned to their former activities. The ultimate results have been most gratifying.

Mount Vernon Place and Cathedral Street.

[8] In fact, delay in the radical treatment is dangerous, as malignant degeneration is not uncommon in certain types of these burns.

Clinical Notes, Suggestions, and New Instruments

MENINGOCOCCUS MENINGITIS WITH RECOVERY IN A SEVEN WEEKS OLD INFANT *

JAMES M. STURTEVANT, M.D., NEW YORK

Meningococcus meningitis is an extremely rare disease in early infancy. Root,[1] in a careful review of the literature up to 1921, found only six cases of meningococcus meningitis occurring in infants under 2 months of age; two of these infants died during the acute stage of the disease, three died a few months later from sequelae, and the remaining case could not be traced. A seventh case is reported by Cook and Bell[2] in a child, aged 17 days, with a fulminating infection of parameningococcus and an extensive petechial rash.

In view of these facts, recovery without sequelae in an infant, aged 7 weeks, following specific serum therapy administered into the cisterna magna, seems of sufficient interest to merit publication.

REPORT OF CASE

D. H., a white girl, born, Jan. 31, 1925, was admitted to the Babies' Hospital, March 23, at the age of 7 weeks. The chief complaint was convulsions and vomiting of three hours' duration, following the sudden onset of fever (105 F.) first noticed twenty-four hours before. Prior to this time the baby was said to have been entirely well. The family history was unimportant. The patient was the result of the only pregnancy, full term, normal labor, birth weight, 7 pounds 9 ounces (3.5 Kg.). Owing to failure of the mother's milk, the baby had been breast fed only one week. Since that time she had been fed on modified milk formulas.

When first examined on admission it was observed that the anterior fontanel was of normal size and not bulging. The extremities were slightly spastic. There was slight internal strabismus. The patellar reflexes were active. These symptoms of irritation promptly subsided. The head measured 14¼ inches (36 cm.); chest, 13 inches (32.5 cm.); abdomen, 11½ inches (29 cm.); length, 21 inches (53 cm.). The infant was fairly well nourished. When disturbed, she had a strong, vigorous cry. There were no symptoms indicating a severe infectious process. Her attitude and movements appeared normal. The eyes moved normally. There was no internal strabismus and no nystagmus. The pupils were pinhead in size and reacted slowly to light. The ears, nose, mouth and pharynx were normal. The neck was not rigid. The head could be flexed on the chest and laterally with no apparent signs of tenderness. The thorax was symmetrical. The lungs were clear and the heart sounds were normal. The spleen was palpable at the costal border. The liver was palpable one-half inch below the costal border. The abdomen was not tender. There was no weakness, paralysis or rigidity of the extremities. The tendon reflexes were definitely increased. Urinalysis showed the presence of a few leukocytes but neither albumin nor casts. Because of the history of convulsions and vomiting and the rather indefinite physical findings, lumbar puncture seemed indicated. Only 1 cc. of thick pus was obtained, which on direct smear showed 99 per cent polymorphonuclear leukocytes with occasional gram-negative biscuit shaped diplococci both within and without the cells. Further attempts at obtaining fluid by lumbar puncture were unsuccessful. On being tapped, the cisterna magna yielded 35 cc. of turbid fluid under pressure. This fluid contained 4,600 cells per cubic millimeter, 99 per cent of which were polymorphonuclears. The globulin was 4 plus. There was no sugar reduction obtained with Benedict's test. The quantitative test for sugar showed 32 mg. per hundred cubic centimeters of cerebrospinal fluid. The chlorides were 663 mg. per hundred cubic centimeters. Cultures of the fluid from the cisterna magna grew meningococci.

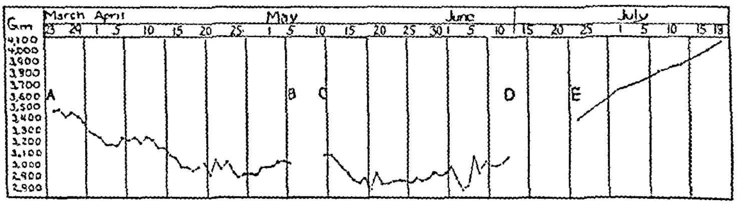

Chart 1.—Changes in weight: *A*, on admission; *B*, discharge; *C*, readmission; *D*, discharge; *E*, admission to outpatient department. July 18, the patient's weight was 4,150 Gm., or approximately 9 pounds; four months later, November 20, it was 15 pounds 4 ounces (7 Kg.); this represents a net gain of 6 pounds 4 ounces (2.8 Kg.) in the first four months following her discharge from the hospital.

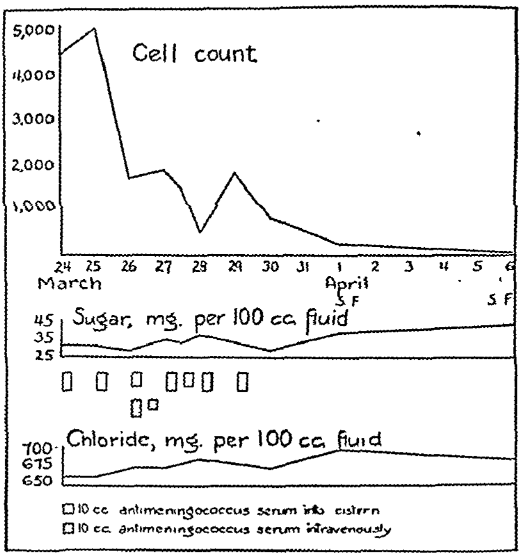

Chart 2.—Cell count and chemical findings.

Immediately 20 cc. of New York State Department of Health antimeningococcus serum was injected into the cisterna magna and 20 cc. was given intravenously. The following day this procedure was repeated, after which no further serum was given intravenously. Five more injections were made into the cisterna magna, 20 cc. being injected each time over a period of five days. The blood culture, which was not taken until after the initial dose of serum had been given, was sterile. From the onset of treatment the condition of the patient improved slowly and steadily. Fourteen days after the first lumbar puncture, when only a few drops of pus were obtained and complete blocking of the spinal canal was evident, the spinal fluid had become clear and only 40 cells per cubic millimeter were present. The spinal fluid sugar had increased during these fourteen days from 28 mg. to 43 mg., with a proportionate rise in the chloride content from 675 mg. to 688 mg. per hundred cubic centimeters. There was a complicating otitis media, which also gradually improved. Cultures from the ear discharge showed no meningococci. The temperature gradually subsided. The white blood cell count had dropped from 23,950 to 15,900. The patient slowly but steadily improved. She was discharged in excellent condition, forty-two days after admission.

Six days following her discharge from the hospital, she was readmitted with a severe attack of bronchopneumonia. This was accompanied by the following signs of meningeal irritation: opisthotonos, rigidity and tenderness of the neck, positive Brudszinsky's sign, and active knee jerks. Lumbar puncture was again done and the spinal fluid was found to be normal. The count showed 8 cells per cubic millimeter and a sugar content of 55 mg. per hundred cubic centimeters.

---

* From the Babies' Hospital, Department of Diseases of Children, Columbia University.

[2] Bell, H. H., and Cooke, J. V.: Am. J. Dis. Child. **24**: 387 (Nov.) 1922.

The pneumococcus infection followed the meningococcus infection so closely that the matter of nutrition became a very serious one, but with careful feeding she was again discharged cured, thirty-one days after the second admission. From that time to the present date she has been seen weekly in the outpatient department. There has been a slow but steady gain in weight, and no apparent sequelae are demonstrable. The accompanying charts show the marked loss of weight at the onset of each acute infection followed by a low maintenance throughout each infection and a very gradual but constant increase in weight since recovery. Chart 2 shows the cytology and chemical analysis of the fluid.

SUMMARY

The chief points of interest in this case of proved meningococcus are:

1. The age of the infant.
2. The mild meningeal symptoms.
3. Complete blocking of the spinal canal, necessitating the administration of seven injections of serum into the cisterna magna.
4. Ability to survive a second acute infection (pneumococcus) within sixty days following the onset of the primary disease.
5. Complete recovery from both infections without complications or sequelae.
6. Present condition and progress normal, nine months after onset of infection.

300 West End Avenue.

TRANSILLUMINATION OF THE CERVIX OF THE UTERUS

Leonard R. Thompson, M.D., San Pedro, Calif.

This procedure is offered primarily as a means of diagnosing the condition of the glands of the cervix.

The cervix may be transilluminated by a light applied to the vaginal surface, or by a small light introduced within the cervical canal. A hooded light must be used when applied to the outer surface of the cervix, so that all the rays are directed into the cervical tissue. A Carroll antrum transilluminator, which has the light at right angles to a straight handle, serves well for this purpose. The position of the light and its intensity must be varied until just the proper illumination is secured. A light from a urethroscope may be used for the inside of the cervix.

The first cervix I examined this way had a definite cyst visible to ordinary examination. Transillumination revealed the cyst as an area more translucent than the rest of the cervix, and clearly defined by the light. Incision of the cyst liberated clear mucus.

A normal cervix does not show, when transilluminated, any areas more translucent than the rest. When the glands are moderately dilated, they may be seen as elongated structures arranged radially around the cervical canal, and extending well into the cervical tissue.

That a cystic condition of the glands very often is not revealed by ordinary examination is demonstrated by the following cases:

A patient, complaining of sterility, showed on examination a milky cervical discharge, and a reddened area on the posterior lip. There was no swelling to suggest a cyst. Transillumination revealed a cystic gland, which very closely corresponded in size and position to the reddened area.

Another patient complained of sterility and moderate vaginal discharge. The cervix was moderately enlarged but had no cystic swellings or reddening. Transillumination showed well marked dilatation of the glands.

In another instance a cervical repair was done in an attempt to cure a cervical discharge. The laceration was repaired, but the discharge continued. Transillumination showed numerous cystic glands, which could have been removed at the time of operation if their presence had been known. The scar tissue at the operation site was more luminous than normal cervical tissue.

Transillumination will be found very valuable in determining the source of a discharge from the cervix. It will demonstrate endocervicitis in some cases in which sterility is the complaint. It will make it possible to determine with greater precision the patients needing an operation of the Sturmdorf type.

Transillumination is such a simple procedure that it should be done as a part of the routine of a pelvic examination.

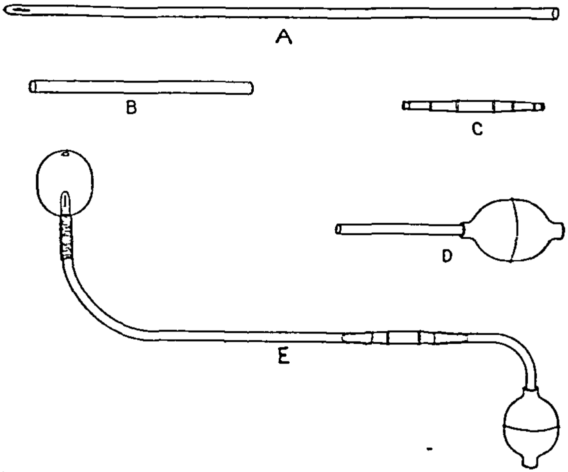
A PROSTATIC BAG

Tom R. Barry, M.D., Knoxville, Tenn.

Various devices to control bleeding after prostatectomy have been described. Many of these are bulky, very painful to remove and are not always available. The chief objections to the use of the Hagner and Pilcher bags are, (1) the necessity of withdrawing the end through the urethra and bladder and out the suprapubic wound, which is extremely painful, difficult and not always aseptic; and (2) the necessity of removing and again replacing the suprapubic drain.

I have used the following simple modification of the Hagner bag with entirely satisfactory results:

The bag consists of a soft rubber catheter 22 F., and a three-eighth inch cigaret drainage tubing, 7 inches long. The tubing is telescoped, making a double thickness 3½ inches long. One end is tied off with silk, and the double is then inverted so that the end will be inside the bag when it is inflated.



Simple modification of Hagner prostatic bag. *A*, catheter; *B*, cigaret drainage tubing; *C*, graduated glass connection tube; *D*, inflating bulb; *E*, apparatus assembled.

The catheter is introduced into the open end of the tube, a free portion 1¾ inches protruding beyond the catheter end. The tubing is secured to the catheter by wrapping with no. 4 silk, beginning at the eye of the catheter and extending forward the entire length of the overlapped drainage tubing (about 1¼ inches), using enough tension to compress the catheter slightly and thereby making an almost even surface. If desired, the ends may be vulcanized instead of wrapped with silk.

This bag will stand an almost unlimited amount of tension and distention and is removed through the urethra without the slightest difficulty and with no more pain than is experienced in the withdrawing of an ordinary catheter. Either air or water dilation may be used.

COMMENT

This device has four distinct advantages over the Hagner bag:

1. It is inexpensive and always available.
2. It is easily removed.
3. When the air is out, it may be left in place several days without causing discomfort.
4. Being soft, it more nearly conforms to the prostatic bed than the older types.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1349)

DOSAGE OF DRUGS

Personal Peculiarities.—In order to be successful in the practice of medicine, it must be remembered that we are not treating a disease but a patient, and that it is essential to consult the peculiar tendencies of the man or woman who is the patient. For this purpose, what is popularly known as "a knowledge of the constitution" is necessary. This is a knowledge that can be gained only by experience, and for the acquisition of which obviously but little help can be given by generalizations. Still, some of the factors may be pointed out that go to make up "the constitution."

It is the knowledge of hereditary tendencies that makes the advice of the old family physician sometimes so valuable. The habits of life are of importance. Hard physical work and habitual exposure to weather render the system less sensitive; refinement, luxury and indolence, more sensitive to disturbing agencies. Thus, a laboring man may have to receive twice the dose that would be sufficient for a professional man.

Habituation to drugs is another factor that must be reckoned with. The human system has a remarkable power of acquiring tolerance to the influence of certain drugs, so that progressively larger doses have to be given to obtain the same effect. This renders an alcoholic patient peculiarly insusceptible to the influence of alcohol and of closely allied agencies, such as ether or chloral; an opium habitué may require several times the dose of opiate that would be fatal to an ordinary person. This also explains the reason why a drug that acts well at first often loses its effect after a while; and why in the treatment of chronic diseases it often becomes necessary to substitute one remedy for another of the same class, in order to obtain renewed benefit; such remedies that are interchangeable are termed "succedanea." An extensive range of succedanea in the possession of the physician greatly increases his power to do good. The practitioner who knows one dozen drugs well is not so good a physician as one who knows three or four dozen drugs well. Preaching parsimony in the teaching of materia medica is just now popular. While it is better to know all about a dozen drugs than a little about a hundred, let us, in the interest of efficiency, equip ourselves thoroughly with a liberal armamentarium in the fight against disease.

Temperaments, or the peculiarities of classes of individuals, have to be taken into account. Persons of the nervous temperament generally require smaller doses than the phlegmatic. Idiosyncrasies, the peculiarities of individuals, cannot be known except as the result of experience. Idiosyncrasy, which shows itself as an exceptional indifference, an exceptional susceptibility, or an exceptional mode of reaction, occurs in relation not only to drugs but also to foods. It is expressed in the old saying: "One man's meat is another man's poison." It must be admitted, however, that calling such exceptional reactions idiosyncrasy is merely substituting a well sounding word for our ignorance, using a cloak for our inability to explain matters. A well defined idiosyncrasy should challenge us to endeavors to determine the cause. Thus, marked intolerance to drugs in general should furnish a strong hint to investigate the condition of the kidney; it may be due to cumulative action; i. e., greater absorption than excretion. An exceptional mode of reaction may be due to greater prominence in the individual, as the vagotonic or the sympatheticotonic, of certain well defined side actions of drugs (untoward effects), which in others would occur only as a result of excessively large doses.

Temporary Conditions.—These likewise are important. The time of administration modifies the action of drugs. A full stomach delays general and lessens local action. A smaller dose of an agent will produce an action when it is given so that its effect coincides with the natural time of that action than when it is given out of season. Hypnotics are most effective in the evening; purgatives should be administered so as to act at the accustomed time of evacuation. During menstruation, certain remedies have a special action. Purgatives tend to increase the flow. At this time it is wise to use all very active drugs with special care, or abandon them temporarily. During pregnancy, powerful purgatives may cause abortion. During pregnancy as well as during lactation, we must always bear in mind the action which the drug may have on the child, for many drugs pass from mother to child. It is probable that emotions influence the activity of drugs, favoring or hindering their action; and the physician who fails to avail himself in disease of "expectant attention," who does not explain to the patient the effect he intends the remedy to have, drops an important article from his list of remedial agents.

Disease.—This exerts a most profound influence on the action of remedies. Remedies that directly antagonize a disease or disorder are generally well borne and required in large doses, while at other times the action of a remedy may be increased to an unexpected extent by the presence in the body of an agency acting in the same direction. Certain remedies produce in disease a characteristic effect that is not obtained in health; the antipyretics reduce the temperature in fever, but have no effect on it in health. Other remedies which have a certain action on normal tissues may fail to produce this action in disease because the tissue may not be sufficiently sound to be acted on; thus, digitalis may fail to increase the working power of a fatty heart, and the nitrites may be unable to dilate sclerotic vessels. Local disease may contraindicate a remedy otherwise indicated; gastro-intestinal irritation contraindicates most of the tonics, bitters, iron preparations and cod liver oil; congestion or irritation of the middle ear would contraindicate quinine or demand its most cautious employment.

Method of Administration.—The remedy, especially the method of its administration, requires modification of dose; thus, the hypodermic dose is generally one-half, the rectal dose twice the dose by mouth. There are, however, important exceptions to this rule. Combination with another remedy having the same effect in the body (synergist) lessens the dose necessary of each.

---

* This is the nineteenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

When an unusually large dose of a dangerous remedy is prescribed, as of morphine for a morphine habitué, it should be marked in some way to show that such a dose is intended, and not written by error. Probably the best way of doing this is to write the quantity both in numerals and in words, in parenthesis, as in the following example:

Patient's name.[50]
Patient's ailment.[50]
Patient's address.[50]
℞ Morphine sulphate....... 0.25 Gm. (twenty-five centigrams).
Lactose .... 0.50 Gm.
M. and divide into 5 caps.
S.: One every four hours as needed.
Physician's name and address[50] and registration number[50] under the Harrison Act.

It may be well to write, in addition, at the bottom of the prescription: "The above is just as intended." All this should be done to avoid delay, as a careful pharmacist may hesitate to put up such a prescription without consulting the physician about it. Such hesitation is entirely justified, for the pharmacist may be held criminally liable with the physician if he compounds and dispenses a medicine containing a fatal dose of poison.

DOSE CALCULATION IN PRESCRIBING

After the dose and the time and frequency of its administration have been decided on, the next question that arises is to determine the total number of doses to be prescribed. For this purpose, one should find the number of doses to be taken in a day, and decide on the number of days the medicine is to last. Dividing 16 by the number of hours of interval between the administration of the separate doses, and adding 1, will give the number of doses in a day. Thus, if the patient take a dose of medicine every three hours, he will take six doses ($16 \div 3 = 5$; $5 + 1 = 6$) in one day. In such calculations, of course, one may ignore fractions. Sixteen hours a day are figured on, as the other eight hours are supposed to be taken up by sleep. It is seldom necessary to rouse a patient to take medicine, as sleep is generally of as much importance as drugs.

In determining the number of days the medicine is to last, one should rather err in prescribing too small than too large a quantity. It is better to have the prescription refilled over and over again than to risk having half a bottle set aside unused. Patients will rarely complain of the cost of medicines that are consumed; but they will observe the waste and criticize, when repeatedly forced to set aside half-used remedies to buy others. Hence it is a wise general rule to order only sufficient medicine to last from one visit to the next. This applies especially to acute cases, in which the condition of the patient may change from day to day, or even from hour to hour. When, however, a prolonged course of a certain remedy is needed, it may save expense and trouble if a larger quantity is ordered at a time.

Multiplying the number of doses for one day by the number of days the medicine is to last will give the total number of doses. This figure should now be modified and rounded out, if necessary, to conform to the system of weights used: the multiples or convenient subdivisions of 10 for the metric system. This facilitates the further calculations. Thus, if a dose of medicine is given every two hours, the total daily dose may be calculated as ten times the amount of the single dose.

VARIETIES OF LIQUID MEDICINES

In the prescribing of liquid dosage forms, solutions should be preferred to "shake mixtures" or emulsions, for both of the latter have in addition to a certain degree of unsightliness, and the possibility that the patient may forget to shake the bottle, a tendency to separation of the ingredients into layers, occurring in some cases so rapidly as to introduce an uncertainty in dosage. Still, as "shake mixtures" and emulsions have a certain practical, even though limited, value, the liquid dosage forms will be taken up in this order: solutions; "shake mixtures"; emulsions.

SOLUTIONS

The first necessity for the proper prescribing of solutions is a knowledge of solubilities. Such knowledge, thorough enough, also protects us against many incompatibilities, which are questions of solubility. Physical incompatibility depends on the fact that no substance is equally soluble in various liquids, so that when a solution is mixed with a considerable proportion of a liquid in which the solute is insoluble, precipitation occurs. A study of solubility, for practical purposes, would lead us too far afield to be taken up here. After all, the solubility of each important substance must be memorized separately; and, whenever we are uncertain of the result of the mixing of two different bodies, a simple experiment, which any pharmacist will always gladly perform for a physician, will quickly demonstrate the facts. Sometimes, as the Germans say, "Probieren geht über das Studieren" (trying is better than studying).

Treatises on pharmacy differentiate carefully between extractive and nonextractive preparations. From the physician's standpoint, the distinction is of minor importance. He must, however, be familiar with the characteristics of the various classes.

From the time that man entered the stone age, he has been intent on improving on nature. This is just as evident in the practice of medicine as in other human endeavors. Chewing and swallowing the crude herb was displaced, even in prehistoric times, by infusions and decoctions, which still are the main medicinal preparations of drugs in the hands of primitive peoples.

Infusions are simply teas, made by pouring boiling water on the coarsely comminuted drug, covering the vessel tight, allowing it to stand for half an hour, and then straining the fluid with pressure. The formula for infusions, contained in the Pharmacopeia, directs them to be made 5 per cent strength unless otherwise directed by the physician. The only remaining representative in the Pharmacopeia of this once large class of preparations is the infusion of digitalis (1.5 per cent strength), which is by some physicians believed to be more diuretic than other extractive preparations of this drug. Its average dose is stated by the Pharmacopeia at 6 cc.; but it is often given, at first, in tablespoonful (15 cc.) doses every four hours: and it is probably this liberality in the dosage of the infusion, as compared with insufficient dosage of the tincture habitually employed by many, that accounts for superior results. The National Formulary still harbors several infusions, the most important of which is the compound infusion of senna, a relic of the barbarous past when such horribly tasting teas had to be consumed by the teacupful. (The N. F. average dose is 120 cc.) This preparation is sometimes useful, however, as a purgative in constipation resisting milder means, for it is a rational synergistic combination of senna (6 per cent) which excites

CHICAGO

(Continued from page 1349)

DOSAGE OF DRUGS

Personal Peculiarities.—In order to be successful in the practice of medicine, it must be remembered that we are not treating a disease but a patient, and that it is essential to consult the peculiar tendencies of the man or woman who is the patient. For this purpose, what is popularly known as "a knowledge of the constitution" is necessary. This is a knowledge that can be gained only by experience, and for the acquisition of which obviously but little help can be given by generalizations. Still, some of the factors may be pointed out that go to make up "the constitution."

It is the knowledge of hereditary tendencies that makes the advice of the old family physician sometimes so valuable. The habits of life are of importance. Hard physical work and habitual exposure to weather render the system less sensitive; refinement, luxury and indolence, more sensitive to disturbing agencies. Thus, a laboring man may have to receive twice the dose that would be sufficient for a professional man.

Habituation to drugs is another factor that must be reckoned with. The human system has a remarkable power of acquiring tolerance to the influence of certain drugs, so that progressively larger doses have to be given to obtain the same effect. This renders an alcoholic patient peculiarly insusceptible to the influence of alcohol and of closely allied agencies, such as ether or chloral; an opium habitué may require several times the dose of opiate that would be fatal to an ordinary person. This also explains the reason why a drug that acts well at first often loses its effect after a while; and why in the treatment of chronic diseases it often becomes necessary to substitute one remedy for another of the same class, in order to obtain renewed benefit; such remedies that are interchangeable are termed "succedanea." An extensive range of succedanea in the possession of the physician greatly increases his power to do good. The practitioner who knows one dozen drugs well is not so good a physician as one who knows three or four dozen drugs well. Preaching parsimony in the teaching of materia medica is just now popular. While it is better to know all about a dozen drugs than a little about a hundred, let us, in the interest of efficiency, equip ourselves thoroughly with a liberal armamentarium in the fight against disease.

Temperaments, or the peculiarities of classes of individuals, have to be taken into account. Persons of the nervous temperament generally require smaller doses than the phlegmatic. Idiosyncrasies, the peculiarities of individuals, cannot be known except as the result of experience. Idiosyncrasy, which shows itself as an exceptional indifference, an exceptional susceptibility, or an exceptional mode of reaction, occurs in relation not only to drugs but also to foods. It is expressed in the old saying: "One man's meat is another man's poison." It must be admitted, however, that calling such exceptional reactions idiosyncrasy is merely substituting a well sounding word for our ignorance, using a cloak for our inability to explain matters. A well defined idiosyncrasy should challenge us to endeavors to determine the cause. Thus, marked intolerance to drugs in general should furnish a strong hint to investigate the condition of the kidney; it may be due to cumulative action; i. e., greater absorption than excretion. An exceptional mode of reaction may be due to greater prominence in the individual, as the vagotonic or the sympatheticotonic, of certain well defined side actions of drugs (untoward effects), which in others would occur only as a result of excessively large doses.

Temporary Conditions.—These likewise are important. The time of administration modifies the action of drugs. A full stomach delays general and lessens local action. A smaller dose of an agent will produce an action when it is given so that its effect coincides with the natural time of that action than when it is given out of season. Hypnotics are most effective in the evening; purgatives should be administered so as to act at the accustomed time of evacuation. During menstruation, certain remedies have a special action. Purgatives tend to increase the flow. At this time it is wise to use all very active drugs with special care, or abandon them temporarily. During pregnancy, powerful purgatives may cause abortion. During pregnancy as well as during lactation, we must always bear in mind the action which the drug may have on the child, for many drugs pass from mother to child. It is probable that emotions influence the activity of drugs, favoring or hindering their action; and the physician who fails to avail himself in disease of "expectant attention," who does not explain to the patient the effect he intends the remedy to have, drops an important article from his list of remedial agents.

Disease.—This exerts a most profound influence on the action of remedies. Remedies that directly antagonize a disease or disorder are generally well borne and required in large doses, while at other times the action of a remedy may be increased to an unexpected extent by the presence in the body of an agency acting in the same direction. Certain remedies produce in disease a characteristic effect that is not obtained in health; the antipyretics reduce the temperature in fever, but have no effect on it in health. Other remedies which have a certain action on normal tissues may fail to produce this action in disease because the tissue may not be sufficiently sound to be acted on; thus, digitalis may fail to increase the working power of a fatty heart, and the nitrites may be unable to dilate sclerotic vessels. Local disease may contraindicate a remedy otherwise indicated; gastro-intestinal irritation contraindicates most of the tonics, bitters, iron preparations and cod liver oil; congestion or irritation of the middle ear would contraindicate quinine or demand its most cautious employment.

Method of Administration.—The remedy, especially the method of its administration, requires modification of dose; thus, the hypodermic dose is generally one-half, the rectal dose twice the dose by mouth. There are, however, important exceptions to this rule. Combination with another remedy having the same effect in the body (synergist) lessens the dose necessary of each.

---

* This is the nineteenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

When an unusually large dose of a dangerous remedy is prescribed, as of morphine for a morphine habitué, it should be marked in some way to show that such a dose is intended, and not written by error. Probably the best way of doing this is to write the quantity both in numerals and in words, in parenthesis, as in the following example:

Patient's name.[50]
Patient's ailment.[50]
Patient's address.[50]

℞ Morphine sulphate....... 0.25 Gm. (twenty-five centigrams).
Lactose .... 0 50 Gm.
M. and divide into 5 caps.
S.: One every four hours as needed.
Physician's name and address[50] and registration number[50] under the Harrison Act.

It may be well to write, in addition, at the bottom of the prescription: "The above is just as intended." All this should be done to avoid delay, as a careful pharmacist may hesitate to put up such a prescription without consulting the physician about it. Such hesitation is entirely justified, for the pharmacist may be held criminally liable with the physician if he compounds and dispenses a medicine containing a fatal dose of poison.

DOSE CALCULATION IN PRESCRIBING

After the dose and the time and frequency of its administration have been decided on, the next question that arises is to determine the total number of doses to be prescribed. For this purpose, one should find the number of doses to be taken in a day, and decide on the number of days the medicine is to last. Dividing 16 by the number of hours of interval between the administration of the separate doses, and adding 1, will give the number of doses in a day. Thus, if the patient take a dose of medicine every three hours, he will take six doses ($16 \div 3 = 5$; $5 + 1 = 6$) in one day. In such calculations, of course, one may ignore fractions. Sixteen hours a day are figured on, as the other eight hours are supposed to be taken up by sleep. It is seldom necessary to rouse a patient to take medicine, as sleep is generally of as much importance as drugs.

In determining the number of days the medicine is to last, one should rather err in prescribing too small than too large a quantity. It is better to have the prescription refilled over and over again than to risk having half a bottle set aside unused. Patients will rarely complain of the cost of medicines that are consumed; but they will observe the waste and criticize, when repeatedly forced to set aside half-used remedies to buy others. Hence it is a wise general rule to order only sufficient medicine to last from one visit to the next. This applies especially to acute cases, in which the condition of the patient may change from day to day, or even from hour to hour. When, however, a prolonged course of a certain remedy is needed, it may save expense and trouble if a larger quantity is ordered at a time.

Multiplying the number of doses for one day by the number of days the medicine is to last will give the total number of doses. This figure should now be modified and rounded out, if necessary, to conform to the system of weights used: the multiples or convenient subdivisions of 10 for the metric system. This facilitates the further calculations. Thus, if a dose of medicine is given every two hours, the total daily dose may be calculated as ten times the amount of the single dose.

VARIETIES OF LIQUID MEDICINES

In the prescribing of liquid dosage forms, solutions should be preferred to "shake mixtures" or emulsions, for both of the latter have in addition to a certain degree of unsightliness, and the possibility that the patient may forget to shake the bottle, a tendency to separation of the ingredients into layers, occurring in some cases so rapidly as to introduce an uncertainty in dosage. Still, as "shake mixtures" and emulsions have a certain practical, even though limited, value, the liquid dosage forms will be taken up in this order: solutions; "shake mixtures"; emulsions.

SOLUTIONS

The first necessity for the proper prescribing of solutions is a knowledge of solubilities. Such knowledge, thorough enough, also protects us against many incompatibilities, which are questions of solubility. Physical incompatibility depends on the fact that no substance is equally soluble in various liquids, so that when a *solution is mixed with a considerable proportion of a* liquid in which the solute is insoluble, precipitation occurs. A study of solubility, for practical purposes, would lead us too far afield to be taken up here. After all, the solubility of each important substance must be memorized separately; and, whenever we are uncertain of the result of the mixing of two different bodies, a simple experiment, which any pharmacist will always gladly perform for a physician, will quickly demonstrate the facts. Sometimes, as the Germans say, "Probieren geht über das Studieren" (trying is better than studying).

Treatises on pharmacy differentiate carefully between extractive and nonextractive preparations. From the physician's standpoint, the distinction is of minor importance. He must, however, be familiar with the characteristics of the various classes.

From the time that man entered the stone age, he has been intent on improving on nature. This is just as evident in the practice of medicine as in other human endeavors. Chewing and swallowing the crude herb was displaced, even in prehistoric times, by infusions and decoctions, which still are the main medicinal preparations of drugs in the hands of primitive peoples.

Infusions are simply teas, made by pouring boiling water on the coarsely comminuted drug, covering the vessel tight, allowing it to stand for half an hour, and then straining the fluid with pressure. The formula for infusions, contained in the Pharmacopeia, directs them to be made 5 per cent strength unless otherwise directed by the physician. The only remaining representative in the Pharmacopeia of this once large class of preparations is the infusion of digitalis (1.5 per cent strength), which is by some physicians believed to be more diuretic than other extractive preparations of this drug. Its average dose is stated by the Pharmacopeia at 6 cc.; but it is often given, at first, in tablespoonful (15 cc.) doses every four hours: and it is probably this liberality in the dosage of the infusion, as compared with insufficient dosage of the tincture habitually employed by many, that accounts for superior results. The National Formulary still harbors several infusions, the most important of which is the compound infusion of senna, a relic of the barbarous past when such horribly tasting teas had to be consumed by the teacupful. (The N. F. average dose is 120 cc.) This preparation is sometimes useful, however, as a purgative in constipation resisting milder means, for it is a rational synergistic combination of senna (6 per cent) which excites intestinal peristalsis, with magnesium sulphate (12 per cent), which acts chiefly by retaining fluid in the lower bowel. The presence of manna (12 per cent) and fennel (2 per cent) is chiefly indicative of an ineffectual attempt at disguising.

---

[50] The five special items required on prescriptions for opiates or coca derivatives, in accordance with the Harrison Narcotic Law.

Decoctions are made by boiling the coarsely ground or cut drug (5 per cent) with water for fifteen minutes, allowing it to cool, and then straining. Boiling the drug is more powerful as an extraction process than infusion; but it tends to dissipate some of the volatile materials of the drug and may injure some of the more delicate organic principles. Hence decoction should be employed in the extraction of only those drugs that are not injured by heat.

The worst disadvantage of infusions and decoctions is their poor keeping quality. Even the official infusion of digitalis, which contains 10 per cent of alcohol and 15 per cent of cinnamon water as preservatives, does not keep for more than a few days in hot weather. It should therefore be recently prepared in fairly small quantities, and kept in the icebox until consumed.

An important step in advance was made when wine and vinegar came to be employed for the extraction of drugs. These are for many active principles of drugs much better solvents than is water, and they also have a preservative action. Now there is but one vinegar in the U. S. P., the vinegar of squill; and wines have been deleted completely. The distillation of alcohol and the superiority as menstruums of mixtures of alcohol and water in definite proportions to the older solvents is chiefly responsible for this.

Tinctures and fluidextracts are now the predominant liquid extractive preparations. The tinctures, representing at an average 10 per cent of drug, are the most important liquid preparations of toxic drugs; while the fluidextracts, representing 100 per cent of drug (1 cc. = 1 Gm.) are generally the most important liquid preparations of nontoxic drugs. In case of the latter, concentration has the advantage of small bulk of dose, and in some cases giving the active principles of the drug the opportunity of developing their action without being complicated or even overshadowed by the effect of alcohol. It is uneconomical, on the other hand, to go to a good deal of trouble to produce as concentrated a preparation as a fluidextract of a drug the dose of which will be only a few drops, and which will be diluted again before taking. The chief reason why fluidextracts of some highly poisonous drugs are still official is that veterinarians are making good use of them. When either a tincture or a fluidextract is to be diluted in a prescription, the best diluent is a mixture of alcohol and of water in as nearly as possible the same proportion as that of water and alcohol in the menstruum, because an alcoholic extractive preparation is more or less incompatible with alcohol as well as with water in accordance with the degree to which they deviate from the proportions present in the menstruum.

(To be continued)

Voluntary Health Agencies.—The relation of the municipal service to the existing voluntary health agencies is an important one. Much of the work carried on in many communities will continue to be given by the voluntary agencies for the present. There should, however, be permitted no real division of responsibility, and the general supervision of all the service that is rendered to the community should be centralized under the direction of the health officer in order to guarantee a well balanced program.—Cumming, Hugh: *Pub. Health Rep.* **41**:380 (Feb. 26) 1926.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

PITUITARY BODY ANTERIOR LOBE, DESICCATED-MULFORD.—The anterior lobe of the pituitary body of cattle, separated, dried and powdered without the addition of preservative or diluent.

Actions and Uses.—See Pituitary Gland, New and Nonofficial Remedies, 1925, p. 260.

Dosage.—From 0.06 to 0.6 Gm. (1 to 10 grains).

Manufactured by the H. K. Mulford Company, Philadelphia. No U. S. patent or trademark.

Tablets Pituitary Body Anterior Lobe, Desiccated-Mulford, 2½ grains.
Tablets Pituitary Body Anterior Lobe, Desiccated-Mulford, 5 grains.

Pituitary body anterior lobe desiccated-Mulford is a light grayish-yellow powder with a slight, peculiar odor. It is partly soluble in water. One part represents approximately 5 parts of the fresh substance.

STERILE SOLUTION OF ANTERIOR LOBE PITUITARY EXTRACT-MULFORD.—An extract of the anterior lobe of the pituitary body of cattle, preserved by the addition of 0.5 per cent of phenol.

Actions and Uses.—See Pituitary Gland, New and Nonofficial Remedies, 1925, p. 260.

Dosage.—Usually 1 cc. (15 minims).

Manufactured by the H. K. Mulford Company, Philadelphia. No U. S. patent or trademark.

Ampules Sterile Solution of Anterior Lobe Pituitary Extract-Mulford, 1 cc.

Sterile solution of anterior lobe pituitary extract-Mulford is prepared by macerating the anterior lobes of the pituitary of cattle with acidulated water. This is strained, filtered through porcelain, and preserved by the addition of 0.5 per cent of phenol.

Each cubic centimeter represents the extractive of 0.2 Gm. of fresh substance.

PITUITARY SOLUTION SURGICAL-WILSON.—An extract of the posterior lobe of the pituitary body of cattle, preserved by the addition of chlorbutanol, each cubic centimeter containing 0.005 Gm. It is standardized by the method of the U. S. Pharmacopeia to have twice the strength of Solution of Pituitary, U. S. P.

Actions, Uses and Dosage.—See Pituitary Gland, New and Nonofficial Remedies, 1925, p. 260.

Manufactured by The Wilson Laboratories, Chicago. No U. S. patent or trademark.

Ampoules Pituitary Solution Surgical-Wilson, 1 cc.

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (See THE JOURNAL, May 2, 1925, p. 1338).
H. K. Mulford Company, Philadelphia.

Scarlet Fever Streptococcus Antitoxin Concentrated.—It is prepared by the method of Drs. Dick under U. S. patent 1,547,369 (July 28, 1925; expires 1942) by license of the Scarlet Fever Committee, Inc. The serum is concentrated by the method employed in concentrating diphtheria antitoxin. Each cubic centimeter neutralizes at least 15,000 skin test doses of scarlet fever toxin. Marketed in packages of one syringe containing 7 cc. (prophylactic dose) and in packages of one syringe containing 14 cc. (therapeutic dose).

CORPORA LUTEA SOLUBLE EXTRACT-P. D. & CO.—A solution of an extract of desiccated corpus luteum in physiological solution of sodium chloride, each cubic centimeter containing 0.02 Gm. of soluble extract, preserved by the addition of 0.5 per cent of chlorbutanol.

Actions and Uses.—See Ovary, New and Nonofficial Remedies, 1925, p. 251.

Dosage.—One cubic centimeter at intervals of one to four days.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent or trademark.

Ampules Corpora Lutea Soluble Extract-P. D. & Co., 1 cc.

Corpora lutea soluble extract-P. D. & Co. is made by extracting desiccated corpus luteum with water slightly acidulated with acetic acid, containing 0.5 per cent of chlorbutanol. The extract is filtered, concentrated in a vacuum at low temperature and precipitated by a solvent miscible with the solution, such as alcohol or acetone. The precipitate is collected, dried at a low temperature and dissolved in physiological solution of sodium chloride so that each cubic centimeter contains 0.02 Gm.

PROCEEDINGS OF THE DALLAS SESSION

MINUTES OF THE SEVENTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT DALLAS, TEXAS, APRIL 19-23, 1926

(Concluded from page 1367)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

Wednesday, April 21—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. Eugene S. Kilgore, San Francisco.

Dr. M. L. Graves, Houston, Texas, read a paper on "Diagnostic Criteria in Malignant Disease of the Upper Right Quadrant." Discussed by Dr. Julius Friedenwald, Baltimore.

Dr. Charles N. Meader, Denver, read a paper on "Nontuberculous Peribronchitis Simulating Occult Tuberculosis."

Dr. Meyer A. Rabinowitz, Brooklyn, read a paper on "Rheumatic Pneumonia."

Dr. John A. Lichty, Clifton Springs, N. Y., read a paper on "Cancer of the Lungs with Especial Reference to Increased Incidence Following Recent Influenza Epidemic."

These three papers were discussed by Drs. Paul H. Ringer, Asheville, N. C.; L. J. Moorman, Oklahoma City; John M. Blackford, Seattle; Felix Baum, Denver; E. C. Thrash, Atlanta; Moses Barron, Minneapolis; H. A. Christian, Boston; I. D. Bronfin, Sanatorium, Colo.; Charles N. Meader, Denver; Meyer A. Rabinowitz, Brooklyn, and John A. Lichty, Clifton Springs, N. Y.

Dr. P. S. Hench, Rochester, Minn., read a paper on "Modern Practical Tests of Renal Function." Discussed by Drs. C. W. Dowden, West Baden, Ind.; L. P. Gay, St. Louis, and P. S. Hench, Rochester, Minn.

Dr. Russell L. Cecil, New York, read a paper on "Classification and Treatment of Chronic Arthritis."

Drs. A. G. Young and J. B. Youmans, Ann Arbor, Mich., presented a paper on "The Use of *o*-Iodoxybenzoic Acid in the Treatment of Chronic Arthritis."

These two papers were discussed by Drs. E. E. Irons, Chicago; J. B. Youmans, Ann Arbor, Mich.; Ralph Pemberton, Philadelphia; P. S. Hench Rochester, Minn., and A. G. Young, Ann Arbor, Mich.

Drs. H. A. Christian, Boston, and James S. McLester, Birmingham, Ala., were appointed to serve on the Executive Committee.

Thursday, April 22—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

Dr. Eugene S. Kilgore, San Francisco, read the chairman's address, entitled "Precordial Pain."

Dr. W. L. Bierring, Des Moines, Iowa, read a paper on "Chronic Endocarditis."

Dr. John H. Musser, New Orleans, read a paper on "Chronic Pericarditis: A Discussion of the Clinical and Experimental Aspects."

Dr. Roger S. Morris, Cincinnati, read a paper on "The Clinical Recognition of Pulsus Alternans."

These four papers were discussed by Drs. Willard J. Stone, Pasadena, Calif.; Joseph L. Miller, Chicago; James McLester, Birmingham, Ala.; Meyer Rabinowitz, Brooklyn; Lewellys F. Barker, Baltimore; W. L. Bierring, Des Moines, Iowa, and John H. Musser, New Orleans.

Dr. John Walker Moore, Louisville, read a paper on "Measurements of Cardiac Overload."

Dr. Joseph H. Pratt, Boston, read a paper on "Cardiac Asthma."

Dr. Charles F. Hoover, Cleveland, read a paper on "Bedside Study of Air Hunger."

These three papers were discussed by Drs. G. Canby Robinson, Nashville, Tenn.; J. B. Guthrie, New Orleans; M. D. Levy, Houston, Texas; George Piness, Los Angeles; Joseph H. Pratt, Boston, and Charles F. Hoover, Cleveland.

Dr. Lewellys F. Barker, Baltimore, read a paper on "The Etiology and Treatment of Pernicious Anemia." Discussed by Drs. Russell L. Haden, Kansas City, Mo.; W. L. Bierring, Des Moines, Iowa; Eugene Kilgore, San Francisco, and Lewellys F. Barker, Baltimore.

Friday, April 23—Afternoon

The meeting was called to order at 2 o'clock by the chairman

The following officers were elected: chairman, Rollyn T. Woodyatt, Chicago; vice chairman, M. L. Graves, Houston, Texas; secretary, B. W. Fontaine, Memphis, Tenn.; delegate, H. A. Christian, Boston; alternate, James E. Paullin, Atlanta, Ga.

Dr. Moses Barron, Minneapolis, read a paper on "Some Unique Features of Hodgkin's Disease."

Drs. M. K. Tedstrom, Corinth, Miss., and W. H. Olmsted, St. Louis, presented a paper on "Cholecystography in Diabetes Mellitus."

Dr. Rollin T. Woodyatt, Chicago, read a paper on "Method of Following Treatment in Diabetes."

These three papers were discussed by Drs. I. I. Lemann, New Orleans; Lee Rice, San Antonio, Texas; J. B. Guthrie, New Orleans; Moses Barron, Minneapolis, and Rollin T. Woodyatt, Chicago.

Dr. Clarence L. Andrews, Atlantic City, N. J., read a paper on "Circulatory Tonics Versus Circulatory Depressants in Cardiovascular-Renal Disease, with Hypertension."

Dr. W. J. MacDonald, St. Catherines, Ont., read a paper on "The Use of Liver Extract in the Treatment of High Blood Pressure."

Dr. J. E. Paullin, Atlanta, Ga., read a paper on "Ultimate Results of Essential Hypertension."

These three papers were discussed by Drs. John B. Nichols, Washington, D. C.; H. A. Christian, Boston; Lewellys F. Barker, Baltimore; Eugene S. Kilgore, San Francisco; Walter Shropshire, Yoakum, Texas, and W. J. MacDonald, St. Catherines, Ont.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

Wednesday, April 21—Morning

The meeting was called to order at 9:10 by the chairman, Dr. Dallas B. Phemister, Chicago.

Dr. Arthur Carroll Scott, Jr., Temple, Texas, read a paper on "Cauterization and Cautery Excision of Cancer: A Study of One Thousand Cases." Discussed by Drs. James F. Percy, Los Angeles; Elmer D. Twyman, Kansas City, Mo., and Arthur Carroll Scott, Temple, Texas.

Dr. Frank H. Lahey, Boston, read a paper on "Substernal Goiter."

Dr. Willard Bartlett, St. Louis, read a paper on "Recognition of the Toxic Patient Unsuited to Thyroidectomy."

These two papers were discussed by Drs. A. Bennett Cooke, Los Angeles; Arthur E. Hertzler, Halstead, Kan.; David C. Straus, Chicago; George W. Crile, Cleveland; Frank H. Lahey, Boston, and Willard Bartlett, St. Louis.

Dr. Hugh H. Young, Baltimore, read a paper on "Sterilization of Local and General Infections by Intravenous Injection of Mercurochrome-220 Soluble: Experimental and Clinical Evidence." Discussed by Drs. F. G. Du Bose, Selma, Ala.; R. J. Stroud, Tempe, Ariz.; Frank Hinman, San Francisco, and Hugh H. Young, Baltimore.

Dr. Barney Brooks, Nashville, Tenn., read a paper on "Ligation of the Aorta: A Clinical Experimental Study." Discussed by Drs. Rudolph Matas, New Orleans; J. Shelton Horsley, Richmond, Va., and Barney Brooks, Nashville, Tenn.

Dr. Stuart W. Harrington, Rochester, Minn., read a paper on "The Surgical Treatment of Pulmonary Suppuration." No discussion.

Dr. James E. Thompson, Galveston, Texas, read a paper on "Septal Flats in the Closure of Unilateral Clefts of the Palate."

Dr. George V. I. Brown, Milwaukee, read a paper on "The Surgical Treatment of Cleft Palate: A New Operation Constructed from Parts of Many Old Operative Procedures."

These two papers were discussed by Drs. Vilray Papin Blair, St. Louis; George Morris Dorrance, Philadelphia; Gordon B. New, Rochester, Minn.; George V. I. Brown, Milwaukee, and James E. Thompson, Galveston, Texas.

Thursday, April 22—Morning

The meeting was called to order at 9 o'clock by the chairman.

The following officers were elected: chairman, J. Tate Mason, Seattle; vice chairman, J. de J. Pemberton, Rochester, Minn.; secretary, Frank H. Lahey, Boston; delegate, Urban Maes, New Orleans; alternate, Fordyce B. St. John, New York.

It was moved by Dr. George W. Crile, Cleveland, that the Executive Committee be given power to appoint one member on a committee of three to arrange for a fracture exhibit next year; also a symposium on fractures.

Motion seconded and carried.

Dr. Dallas B. Phemister, Chicago, read the chairman's address.

Dr. Edgar Lorrington Gilcreest, San Francisco, read a paper on "Fractures of the Ankle Joint and of the Lower End of the Tibia and Fibula." Discussed by Drs. Willis Cohoon Campbell, Memphis, Tenn.; Isadore Cohn, New Orleans; David C. Straus, Chicago, and Edgar Lorrington Gilcreest, San Francisco.

Dr. George Morris Dorrance, Philadelphia, read a paper on "Results of Animal Experimentation with Osteoperiosteal Bone Grafts." No discussion.

Dr. Joseph Colt Bloodgood, Baltimore, read a paper on "Diagnosis and Treatment of Benign and Early Malignant Lesions of the Oral Cavity." Discussed by Drs. Albert Compton Broders, Rochester, Minn., and Joseph Colt Bloodgood, Baltimore.

Dr. Thomas G. Orr, Kansas City, Mo., read a paper on "Jejunostomy: A Clinical Review and Experimental Findings." Discussed by Drs. J. Shelton Horsley, Richmond, Va., and Thomas G. Orr, Kansas City, Mo.

Dr. John Adams Wolfer, Chicago, read a paper on "Experimentally Produced Chronic Gastric Ulcer and Its Clinical Significance." Discussed by Drs. Urban Maes, New Orleans; E. Starr Judd, Rochester, Minn., and John Adams Wolfer, Chicago.

Dr. George W. Crile, Cleveland, read a paper on "The Function of the Liver in Its Relation to Operations on the Gallbladder and Ducts." Discussed by Drs. A. S. Lobingier, Los Angeles, and George W. Crile, Cleveland.

Dr. William J. Mayo, Rochester, Minn., read a paper on "The Interrelation of Lesions of the Liver, the Bone Marrow and the Spleen." Discussed by Drs. William D. Haggard, Nashville, Tenn.; Jabez North Jackson, Kansas City, Mo., and William J. Mayo, Rochester, Minn.

Dr. Stanley R. Maxeiner, Minneapolis, read a paper on "Local Anesthesia as an Adjunct in the Treatment of Nontuberculous Lesions in Tuberculosis Patients." Discussed by Drs. Francis Marion Pottenger, Monrovia, Calif.; Alfred Strauss, Chicago, and Stanley R. Maxeiner, Minneapolis.

Friday, April 23—Morning

The meeting was called to order at 9 o'clock by the chairman.

A joint meeting was held with the Section on Nervous and Mental Diseases.

Dr. Ernest Sachs, St. Louis, read a paper on "Definite Level Symptoms Suggesting Spinal Tumor: A Study of Thirty Cases in which Laminectomy was Done." Discussed by Drs. James B. Ayer, Boston; Martin B. Tinker, Ithaca, N. Y., and Ernest Sachs, St. Louis.

The following papers were read as a symposium on "Sympathectomy":

Dr. S. W. Ranson, St. Louis: "The Anatomy of the Sympathetic Nervous System."

Drs. Alexander Forbes and Stanley Cobb, Boston: "Physiology of the Sympathetic Nervous System in Relation to Certain Surgical Problems."

Drs. Loyal E. Davis and Allen B. Kanavel, Chicago: "Sympathectomy in Spasticities of the Extremities."

Dr. Raymond W. McNealy, Chicago: "Periarterial Sympathectomy."

Dr. Elliott C. Cutler, Cleveland: "Sympathectomy in Angina Pectoris."

These five papers were discussed by Drs. Herbert E. Coe, Seattle; Charles S. Venable, San Antonio; Samuel Clark Harvey, New Haven, Conn.; Walter B. Coffey, San Francisco; Alexander Lambert, New York; Arthur Steindler, Iowa City; W. B. Carrell, Dallas, Texas; S. W. Ranson, St. Louis; Alexander Forbes, Boston; Loyal E. Davis, Chicago; Raymond W. McNealy, Chicago, and Elliott C. Cutler, Cleveland.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

Wednesday, April 21—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. George Gray Ward, New York.

Dr. Carey Culbertson, Chicago, read a paper on "Erosion of the Cervix Uteri with Observations on Its Causes, Its Development and Its End-Results."

Dr. C. Jeff Miller, New Orleans, read a paper on "Chronic Endocervicitis: Its Etiology, Symptomatology and Secondary Pelvic Manifestations."

Dr. Harvey B. Matthews, Brooklyn, read a paper on "The Sturmdorf Operation Versus the Cautery in the Treatment of Chronic Endocervicitis."

Drs. B. C. Corbus and V. J. O'Conor, Chicago, presented a paper on "Diathermy in the Treatment of Gonorrheal Endocervicitis."

Dr. George Gellhorn, St. Louis, read a paper on "Syphilis of the Cervix."

Dr. Grant E. Ward, Baltimore, read a paper on "The Treatment of Cancer of the Uterine Cervix."

Dr. Frank W. Lynch, San Francisco, read a paper on "Five Year Results in Treatment of Cervical Cancer."

These seven papers were discussed by Drs. Arthur H. Curtis, Chicago; H. P. Newman, San Diego, Calif.; John O. Polak, Brooklyn; George W. Crile, Cleveland; Channing Barrett, Chicago; Carey Culbertson, Chicago; C. Jeff Miller, New Orleans; Harvey B. Matthews, Brooklyn; B. C. Corbus, Chicago; George Gellhorn, St. Louis; Grant E. Ward, Baltimore, and Frank W. Lynch, San Francisco.

Thursday, April 22—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

Dr. Norris W. Vaux, Philadelphia, read a paper on "The Umbilical Cord." No discussion.

Drs. R. L. Dickinson, New York, and William H. Cary, Brooklyn, presented a paper on "Sterility: Analysis of Cures and Failures."

Dr. Donald Macomber, Boston, read a paper on "Low Calcium as a Cause of Intra-Uterine Mortality."

These two papers were discussed by Drs. George Gellhorn, St. Louis; James F. Cooper, Swampscott, Mass.; William H. Cary, Brooklyn, and Donald Macomber, Boston.

Dr. George Gray Ward, New York, read the chairman's address.

Drs. W. C. Danforth and C. E. Galloway, Evanston, Ill., presented a paper on "Retrodisplacement in Pregnancy and the Puerperium: A Study of One Thousand Private Cases."

Dr. Harold A Miller, Pittsburgh, read a paper on "Morbidity in One Thousand Postpuerperal Women: A Statistical Presentation."

These two papers were discussed by Drs. Channing Barrett, Chicago; Frank W. Lynch, Chicago; John O. Polak, Brooklyn; Otto H. Schwarz, St. Louis; C. E. Galloway, Evanston, Ill., and Harold A. Miller, Pittsburgh.

Dr. Carl Henry Davis, Milwaukee, read a paper on "Observations on Thyroid Hypertrophy and Pregnancy."

Drs. Robert D. Mussey, William A. Plummer and Walter M. Boothby, Rochester, Minn., presented a paper on "Pregnancy Complicating Exophthalmic Goiter and Adenomatous Goiter with Hyperthyroidism."

These two papers were discussed by Drs. Otto H. Schwarz, St. Louis; Joseph L. Baer, Chicago; J. Earl Else, Portland, Ore.; Carl Henry Davis, Milwaukee, and Robert D. Mussey, Rochester, Minn.

Friday, April 23—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Arthur H. Curtis, Chicago; vice chairman, George Gellhorn, St. Louis; secretary, Carl Henry Davis, Milwaukee; delegate, John O. Polak, Brooklyn; alternate, Lucius Burch, Nashville, Tenn.

Dr. J. Earl Else, Portland, Ore., read a paper on "Tuberculosis of the Lower Ileum." Discussed by Drs. I. D. Bronfin, Sanatorium, Colo., and J. Earl Else, Portland, Ore.

Drs. J. P. Pratt, Detroit, and Edgar Allen, Columbia, Mo., presented a paper on "Clinical Tests of the Ovarian Follicular Hormone." Discussed by Drs. Arthur H. Curtis, Chicago, and J. P. Pratt, Detroit.

Dr. James C. Masson, Rochester, Minn., read a paper on "Myomectomy, Hysterectomy and Radium in the Treatment of Uterine Fibromyomas." Discussed by Drs. Arthur H. Curtis, Chicago; Harvey B. Matthews, Brooklyn, and James C. Masson, Rochester, Minn.

Dr. John O. Polak, Brooklyn, read a paper on "Toxemias of Pregnancy: General Considerations."

Dr. J. P. Greenhill, Chicago, read a paper on "Eclampsia at the Chicago Lying-In Hospital."

Dr. Asa B. Davis, New York, read a paper on "Eight Hundred and Fifty Cases of Toxemia with Convulsions at the New York Lying-In Hospital."

Drs. Lyle G. McNeile and John Vruwink, Los Angeles, presented a paper on "Magnesium Sulphate Intravenously in the Treatment of Preeclampsia and Eclampsia."

These four papers were discused by Drs. E. M. Lazard, Los Angeles; Joseph L. Baer, Chicago; Otto H. Schwarz, St. Louis; J. P. Greenhill, Chicago; Asa B. Davis, New York, and John Vruwink, Los Angeles.

SECTION ON OPHTHALMOLOGY

Wednesday, April 21—Morning

The meeting was called to order at 9:15 by the chairman, Dr. Arnold Knapp, New York.

Dr. Arnold Knapp, New York, read the chairman's address, entitled "The Importance to the Practicing Oculist of Contributing to Literature."

Drs. E. V. L. Brown and Ernest E. Irons, Chicago, presented a paper on "Recurrence of Iritis as Influenced by the Removal of Infections."

Dr. William Zentmayer, Philadelphia, read a paper on "The Prostate as a Remote Focus of Infection in Ocular Inflammations."

Dr. Lloyd Mills, Los Angeles, read a paper on "Ocular Disease Occurring in the Course of Nondysenteric Amebiasis."

These three papers were discussed by Drs. George S. Derby, Boston; John O. McReynolds, Dallas, Texas; G. W. Jean, Santa Barbara, Calif.; Albert E. Bulson, Jr., Fort Wayne, Ind.; William H. Crisp, Denver; John Green, Jr., St. Louis; Melville Black, Denver; W. H. Olds, Los Angeles; T. B. Holloway, Philadelphia; John V. Barrow, Los Angeles; W. H. Wilder, Chicago; William C. Finnoff, Denver; Allen Greenwood, Boston; Arnold Knapp, New York; E. V. L. Brown, Chicago, and Lloyd Mills, Los Angeles.

Dr. S. R. Gifford, Omaha, read a paper on "Sympathetic Uveitis Caused by the Virus of Herpes Simplex: Report of Experiments." Discussed by Drs. Everett L. Goar, Houston, Texas; Arnold Knapp, New York, and S. R. Gifford, Omaha.

Drs. Lee Masten Francis and Ivan Koenig, Buffalo, presented a paper on "Retrobulbar Neuritis in Diabetes: Report of Case." Discussed by Drs. H. P. Wagener, Rochester, Minn.; H. L. Hilgartner, Austin, Texas; William Zentmayer, Philadelphia, and Lee Masten Francis, Buffalo.

Dr. William H. Crisp, Denver, read a paper entitled "An Ophthalmic Year Book, Why and How." This paper was discussed by Drs. Edward Jackson, Denver; Arnold Knapp, New York; T. B. Holloway, Philadelphia; W. H. Wilder, Chicago; W. L. Benedict, Rochester, Minn., and William H. Crisp, Denver.

Dr. F. Phinizy Calhoun, Atlanta, Ga., read a paper on "Ocular Symptoms in Subarachnoid Hemorrhage: A Clinical Consideration." No discussion.

Thursday, April 22—Morning

The meeting was called to order at 9 o'clock by the chairman.

Dr. Conrad Berens, Jr., New York, exhibited an iridocapsulotomy scissors.

Dr. Louis D. Green, San Francisco, presented a tropographic chart which automatically registers the muscles involved in paresis of the intra-ocular muscles.

Dr. Charles A. Bahn, New Orleans, presented an instrument for removing corneal foreign bodies.

Dr. G. C. Savage, Nashville, Tenn., presented an instrument for simplifying the study of ocular rotation—a modification of an instrument formerly presented.

Dr. Laura A. Lane, Baltimore, read a paper on "Radium in Ophthalmology: A Further Study, Experimental and Clinical." Discussed by Drs. Sanford M. Withers, Denver; Melville Black, Denver; G. C. Savage, Nashville, Tenn.; E. J. Curran, Kansas City, Mo.; Arnold Knapp, New York; W. H. Wilder, Chicago; W. L. Benedict, Rochester, Minn., and Laura A. Lane, Baltimore.

Dr. Arthur M. Yudkin, New Haven, Conn., read a paper on "The Aqueous Humor: A Critical and Experimental Study" Discussed by Drs. Lawrence T. Post, St. Louis; Arnold Knapp, New York, and Arthur M. Yudkin, New Haven, Conn.

Drs. William H. Stokes, Dallas, Texas, and Walter R. Parker, Detroit, presented a paper on "Intra-Ocular Sarcoma in Children: A Clinical and Pathologic Study of Ten Cases." Discussed by Drs. Henry C. Haden, Houston, Texas; William C. Finnoff, Denver; Conrad Berens, Jr., New York; Richard C. Gamble, Chicago; Mary Knight Asbury, Cincinnati, and Walter R. Parker, Detroit.

Dr. Edward Jackson, Denver, read a paper on "Retinoblastoma and Recent Views of Malignancy." Discussed by Drs. W. G. Gillett, Wichita, Kan.; S. R. Gifford, Omaha; William H. Crisp, Denver; William H. Stokes, Dallas, Texas, and Edward Jackson, Denver.

Dr. E. C. Ellett, Memphis, Tenn., read a paper on "Refractive Changes." Discussed by Drs. T. B. Holloway, Philadelphia; M. M. Cullom, Nashville, Tenn.; G. C. Savage, Nashville, Tenn.; Lloyd Mills, Los Angeles, and E. C. Ellett, Memphis, Tenn.

Dr. William L. Benedict, Rochester, Minn., read a paper on "Blepharochalasis: Report of Three Cases." Discussed by Dr. Conrad Berens, Jr., New York.

Dr. L. Herbert Lanier, Texarkana, Ark., read a paper on "Closure of the Retinal Vessels: Important Aspects in Diagnosis and Management that may be Overlooked." Discussed by Drs. J. M. Woodson, Temple, Texas; H. P. Wagener, Rochester, Minn.; G. W. Jean, Santa Barbara, Calif., and L. Herbert Lanier, Texarkana, Ark.

Before adjournment, the chairman announced the sudden death of Dr. Lee Masten Francis, Buffalo.

Friday, April 23—Morning

The meeting was called to order at 9 o'clock by the chairman.

The secretary read the following letter:

> Philadelphia, April 14, 1926.
>
> *Dr. William C. Finnoff:*—There remains in the bank a cash balance of $96.74 which has been left over from the funds of an international congress of ophthalmology which was held in Washington in April, 1922. As there will be no further occasion for any expense in connection with this meeting, there should be proper disposition made of this fund. It seemed best to Dr. de Schweinitz and myself to present the matter to the three ophthalmological bodies which were active in the organization of the congress, to determine the proper disposition. In all probability the Knapp Fund will appeal to a majority of the contributors. Will you kindly present the matter before the section and obtain their judgment in the matter?
>
> Luther C. Peter.

Dr. John Green, Jr., St. Louis, moved that this balance be transferred to the Knapp Fund. Motion seconded by Dr. Cassius Wescott, Chicago, and carried.

Dr. Harry S. Gradle, Chicago, reported progress in the Committee on Compensation Tables and Visual Economics and asked that the committee be continued.

Dr. Melville Black, Denver, moved that the report be accepted and the committee continued. Motion seconded by Dr. John Green, Jr., St. Louis, and carried.

No report was made by the Committee on Hereditary Blindness. Dr. W. L. Benedict, Rochester, Minn., moved that this committee be discontinued. Motion seconded by Dr. Cassius Wescott, Chicago, and carried.

No report was made by the Committee on Investigation of Ocular Muscles. Dr. W. H. Wilder, Chicago, moved that this committee be discontinued. Motion seconded by Dr. John Green, Jr., St. Louis, and carried.

The secretary read the following paragraph of a letter from Dr. William Campbell Posey, Philadelphia, chairman of the Committee on Visual Standards for Drivers of Motor Vehicles:

"The committee on Visual Tests for Automobile Drivers was continued for the purpose of conferring with the authorities of the A. M. A. as regards test cards, etc., but as the authorities have made no demand on us during the year, it seems to me it would be best to have our committee discontinued."

Dr. Arthur J. Bedell, Albany, N. Y., moved that the committee be discontinued. Motion seconded by Dr. John Green, Jr., St. Louis, and carried.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., stated that the committee on Local Anesthesia in Ophthalmic Work had no report to make, having made a rather extensive report last year which was adopted by the section. Dr. Bulson moved that the committee be discontinued. Motion seconded by Dr. Harry S. Gradle, Chicago, and carried.

The Committee to Cooperate with the Bureau of Standards and Other Committees on Systems of Designating Lenses and Prisms made the following report:

During the past year your committee has found it impossible to reach conclusions regarding the subject referred to it. It is at this time only able to report progress and to ask to be continued for the further consideration of the subject.

Respectfully submitted.

Edward Jackson.
Walter B. Lancaster.

Dr. Melville Black, Denver, moved the acceptance of the report and the continuance of the committee. Motion seconded by Dr. Harry S. Gradle, Chicago, and carried.

The report of the Committee on Optometry was made as in the presession volume.

Dr. E. C. Ellett, Memphis, Tenn., said: We have in this connection a standing committee in cooperation with all of the other special societies. It is made up of members from this section, from the American Ophthalmological Society, from the American Academy, the Triological, the American Otological and the American Laryngological. This committee was created for the purpose of having some central body to which all matters of interest to the practitioners engaged in this specialty could be referred. Of course the otolaryngologist is not interested in this question, and it seems to me that the proper disposition of this matter would be to ask the cooperation of the ophthalmologic societies in a joint standing committee.

Dr. John Green, Jr., St. Louis, moved that the report as printed be accepted. Motion seconded and carried.

Dr. W. H. Wilder, Chicago, moved that a committee of three, made up of representatives from each of the national ophthalmologic societies, be appointed by their presidents, to constitute such a permanent Committee on Optometry, this committee to take up and consider this subject and report to their respective societies the result of their deliberations.

The amendment of Dr. Wilder was accepted by Dr. Ellett, and on being put to vote, carried.

The Chairman being authorized to appoint one member on this committee, appointed Dr. Edward Jackson, Denver.

The Advisory Committee on Trachoma Among the Indians made the following report:

In suggestions offered to the Commissioner of Indian Affairs in regard to the problem of the control of trachoma among the Indians, the committee urged the importance of a careful survey with complete records to determine the prevalence of the disease among the members of the various tribes and nations of Indians.

The committee also urged the importance of prevention of the spread of the disease among Indians not already affected, by proper segregation of active cases in schools and villages so far as feasible, and also by a campaign of education as to the manner in which the disease is conveyed from one to another and the simple measures of cleanliness that will prevent such spread of the trouble.

The committee was gratified to hear from the commissioner that its suggestions were accepted and are being acted on. In a communication of Feb. 16, 1926, he says:

> The work of reducing the morbidity for trachoma has been aggressively carried on the past year. We are continuing our Southwestern trachoma campaign, with three units working. During the last fiscal year our special physicians examined a total of 68,223 Indians, and operated on 8,455. In addition, they treated 5,581 without surgery. This does not include the cases operated on and treated by the regular physicians. We have established a temporary trachoma hospital at Albuquerque with bed capacity for twenty patients, which has been operating at capacity during the greater part of the time. We have also established a trachoma unit at the Laguna, New Mexico, Sanatorium, and it is doing excellent work.
>
> In addition to the active measures we have been stressing the educational and prophylactic phase. We are enclosing a circular that has recently been sent out to the service. In accordance with the suggestions of your committee, we have designated two annual trachoma weeks, during which all workers in the service, including missionaries and ministers, are requested to stress the importance of this problem.
>
> In concluding, the office wishes to again express its appreciation for your helpful suggestions and assistance, and signify its hopefulness that the American Medical Association will continue the services of the committee at its next annual session.

Again in a letter of March 2, 1926, he says:

> Receipt is acknowledged of your letter dated Feb. 27, 1926, concerning the trachoma work in the Indian Service. Concerning the suggestion of your committee that a complete survey is necessary, the office is now making up a permanent record of the trachoma at each agency and school, and we hope eventually to get a complete survey. We now keep a monthly record which will show the number examined, the cases found, and the disposition of each case by jurisdictions.

The circular referred to is directed to superintendents of Indian schools and physicians in the service and insists on certain hygienic details in schools and meeting places looking toward the prevention of the spread of the disease.

The committee is recommending to the House of Delegates the appointment of an additional member to the committee, Dr. Francis I. Proctor, formerly a practicing ophthalmologist in Boston, now residing in Camden, S. C., who is much interested in the subject, and who has time to devote to it.

William Campbell Posey.
Arnold Knapp.
William H. Wilder, Chairman.

Dr. Cassius Wescott, Chicago, moved the adoption of this report. Motion seconded and carried. This committee having been appointed by the House of Delegates, this section takes no action in regard to continuing or discontinuing the committee.

On the Report of the Committee on the Knapp Testimonial Fund as printed in the Presession Volume, Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., said: One thing I wish to stress in connection with this report is the fact that it is not sufficiently representative. In other words, there are not enough members of this section subscribing to the fund. This fund is primarily for the benefit of the Section on Ophthalmology. Originally it was established to help defray some of the expenses of the section that had to be borne by the officers, but now the principal use is to help in original research work. We now have something like $7,000 in good securities, when we should have $25,000. There are 308 subscribers. Each year a letter is sent out from my office to each member whose name is listed in the presession volume, asking for their subscriptions. I would be glad to have suggestions as to some means by which to increase this fund.

Dr. Meyer Wiener, St. Louis, moved the adoption of this report. Motion seconded and carried.

Dr. Bulson said: There has been no auditing committee appointed for the books of this fund, but I have had the books audited each year by the bank where I keep the fund.

Dr. E. C. Ellett, Memphis, Tenn., reported that the Committee on Awarding the Knapp Medal had carefully considered each of the papers that were presented at the last session, and had decided not to make an award of the medal this year.

Dr. John Green, Jr., St. Louis, moved the acceptance of this report. Motion seconded and carried.

The Secretary read the following paragraph from a letter from Dr. William Campbell Posey, Philadelphia:

> As regards the Committee on the National Congress for the Conservation of Vision, it would appear that as this entire matter is now covered by the committee of which Mr. E. Trechor Collins of London is chairman, our committee is entirely superfluous and might well be discontinued.

Dr. George S. Derby, Boston, said: Last year there was a report from this committee, and one of its suggestions was that as a first step toward such a congress the Committee on the Prevention of Blindness might take the initiative in making its survey. The International Committee has sent a report and asked me to read it. They agree with the committee from this section that the time is not ripe for an international congress. This conclusion was reached after several conferences at the London convention last year. The International Committee is much interested in this proposed congress at some future time, and at the proper time will gladly cooperate with the Section on Ophthalmology of the American Medical Association and with such other organizations of this country as may seem desirable in planning for an international congress on the conservation of vision.

Dr. Cassius Wescott, Chicago, moved that the report be accepted and the committee discontinued. Motion seconded by Dr. John Green, Jr., St. Louis, and carried.

Dr. W. H. Wilder, Chicago, said: The American Board for Ophthalmic Examinations is carrying on. We held an examination in Dallas on the 19th. Since we have been organized we have passed something like 525 members and have given them certificates.

We are contemplating the publication of a directory to be distributed rather widely—an alphabetical list and probably also a geographic list. The American Medical Association in its annual directory indicates, as you have observed, in a certain way those who have been certificated by our board, so that our influence is gradually widening and we are beginning to see some results of our work.

The board has never failed to have a quorum present at any of its meetings, and even during the war we had meetings at which all nine members were present. And to further show the loyalty of the board to its work, we have on a number of occasions sat up till the wee sma' hours of the morning in our necessary deliberations at these annual meetings.

Dr. Cassius Wescott, Chicago, moved that the report be accepted. Motion seconded by Dr. Meyer Wiener, St. Louis, and carried.

The Executive Committee made the following report:

In 1924, Dr. Lucien Howe of Buffalo established a fund of $150 to be held by the Trustees of the American Medical Association, the income of which should be used for a medal to be awarded each year, at the discretion of the Executive Committee of the section. This medal is to be awarded for research in ophthalmology or allied branches. Your committee desires to announce that the medal has been awarded this year to Dr. Edward Jackson, Denver.

The question of a Year Book has been taken up by the Executive Committee, who regard it as a problem of great importance to the ophthalmologists of this country. The committee would suggest that this section take some action whereby the Year Book shall be put on a sound financial basis. The committee would suggest that, in order to hasten action, a member be appointed from this section to serve with members who might be appointed from the two other national ophthalmic societies. In other words, that the other ophthalmic societies are invited to form a joint committee with a member from this section to investigate the question of the Year Book, to come to some conclusion if possible, and to report at the next annual meeting of this section.

George S. Derby.
Arnold Knapp.
Thomas B. Holloway.

The following officers were elected: chairman, Dr. John A. Donovan, Butte, Mont.; vice chairman, Dr. William H. Crisp, Denver; Member, Board on Ophthalmic Examinations, Dr. W. H. Wilder, Chicago.

The following men were duly elected members of the Committee on Awarding the Knapp Medal: Dr. Francis Lane, Chicago; Dr. George S. Derby, Boston; Dr. Thomas B. Holloway, Philadelphia.

The Chairman read again the resolution passed by the section at the Chicago session:

> *Resolved,* That it is the sense of the Section on Ophthalmology of the American Medical Association that we deprecate the selling of glasses by the ophthalmologist to his patients in communities where the services of a reliable dispensing optician are available; and
>
> *Resolved,* That the acceptance of a commission or consideration, either directly or indirectly, from an optician or optical house, from the sale of glasses is absolutely contrary to all of our standards of medical ethics and is just as reprehensible as the splitting of fees.

Dr. W. L. Benedict, Rochester, Minn., moved that this section invite the American Ophthalmological Society and the American Academy of Ophthalmology and Otolaryngology to participate in the formation of a committee of three, one man from each of the societies, to carry out the suggestions of the Executive Committee in regard to the Year Book. Motion seconded by Dr. T. B. Holloway, Philadelphia, who suggested that the committee confer on this matter with Dr. W. H. Crisp of Denver. Motion carried.

Dr. E. C. Ellett, Memphis, Tenn., presented a resolution on the death of Dr. Francis.

Dr. Ellett moved the adoption of this resolution, and that a copy be sent to Mrs. Francis. Motion seconded and carried.

The Chairman announced that Dr. Jonas Friedenwald, Baltimore, had been appointed on the Museum Committee to fill the vacancy occasioned by the death of Dr. Marcus Feingold.

Dr. Meyer Wiener, St. Louis, read a paper on "Mucous Membrane from the Middle Turbinate in Plastic Surgery of the Eye." Discussed by Drs. Lloyd Mills, Los Angeles, and Meyer Wiener, St. Louis.

Drs. A. Ray Irvine and M. F. Weymann, presented a paper on "The Effect of Viewing Motion Pictures on Visual Acuity: Preliminary Report." Discussed by Drs. Charles A. Bahn, New Orleans; William H. Crisp, Denver; W. B. Lancaster, Boston, and M. F. Weymann, Los Angeles.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., read a paper on "The Tolerance of Foreign Bodies in the Posterior Segment of the Eye." Discussed by Drs. Ancil Martin, Phoenix, Ariz.; John Green, Jr., St. Louis; Lloyd Mills, Los Angeles; Melville Black, Denver; J. E. Jennings, St. Louis, and Albert E. Bulson, Jr., Fort Wayne, Ind.

Dr. Arthur J. Bedell, Albany, N. Y., read a paper on "The Anterior Lens Capsule: A Clinical and Pathologic Study." Discussed by Drs. W. B. Lancaster, Boston; Harry S. Gradle, Chicago, and Arthur J. Bedell, Albany, N. Y.

Dr. John Green, Jr., St. Louis, read a paper on "Safeguards in Cataract Expression." Discussed by Drs. Clarence King, Cincinnati; H. W. Woodruff, Joliet, Ill.; E. C. Ellett, Memphis, Tenn.; Meyer Wiener, St. Louis; W. B. Lancaster, Boston; Albert N. LeMoine, Kansas City, Mo., and John Green, Jr., St. Louis.

Dr. Archibald E. Chace, Texarkana, Ark., read a paper on "Color Blindness in Industry." Discussed by Drs. J. E. Jennings, St. Louis; R. H. T. Mann, Texarkana, Ark., and Archibald E. Chace, Texarkana, Ark.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

WEDNESDAY, APRIL 21—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Samuel Iglauer, Cincinnati.

Dr. Samuel Iglauer, Cincinnati, read the chairman's address. Discussed by Drs. I. D. Bronfin, Sanatorium, Colo.; Thomas E. Carmody, Denver, and Samuel Iglauer, Cincinnati.

Dr. Fenton B. Turck, New York, read a paper on "Otolaryngology in General Diseases: Clinical Application of the Experimental Findings in Diseases of Metabolism." Discussed by Dr. Burt R. Shurly, Detroit.

Dr. Joseph C. Beck, Chicago, chairman, presented the report of the Examining Board in Otolaryngology.

Examinations were held at Chicago during the academy meeting, at which time fifteen candidates were examined. At Dallas, April 19, sixty-one were examined, and another examination will be held in San Francisco, April 27. There will be another examination in Montreal in connection with the American Triological Society some time in June—the exact date will be published in the various journals. We have appreciated the way we have been treated at the hospital, every facility having been afforded us for this work.

Dr. Beck moved that the report be adopted. Motion seconded and carried.

Dr. Horace Newhart, Minneapolis, presented the following resolution:

> Recognizing the fact that the most effective means for the prevention of deafness consists in the early detection of hearing impairment, thereby giving opportunity for the prompt removal of contributing causes, and believing it to be one of the important functions of our public school authorities to safeguard the integrity of the special sense organs as well as the general health of the school child; therefore be it
>
> *Resolved*, By the Section on Laryngology, Otology and Rhinology of the American Medical Association that it heartily favors the provision by our public school authorities for regular periodic examinations of the hearing acuity of all public school children, such examinations to be adequate to detect even slight degrees of hearing loss; and be it further
>
> *Resolved*, That this resolution be referred to the House of Delegates of the American Medical Association for its endorsement.

Dr. Horace Newhart moved that this resolution be adopted and transmitted to the House of Delegates. Motion seconded and carried.

Dr. Harvey Stallard, San Diego, Calif., read a paper on "Maxillary Deformations." Discussed by Drs. Thomas E. Carmody, Denver; Greenfield Sluder, St. Louis; Eugene R. Lewis, Los Angeles, and Harvey Stallard, San Diego, Calif.

Dr. John J. Shea, Memphis, Tenn., read a paper on "The Surgical Treatment of Acute Suppurative Paranasal Sinusitis." Discussed by Drs. R. C. Lynch, New Orleans; Ross H. Skillern, Philadelphia; Eugene R. Lewis, Los Angeles; George E. Shambaugh, Chicago; F. J. Pratt, Minneapolis, and John J. Shea, Memphis, Tenn.

Dr. Dana W. Drury, Boston, read a paper on "Vertigo: Its Incidence in Endocrine Disorders." Discussed by Drs. Eugene R. Lewis, Los Angeles, and Dana W. Drury, Boston.

Dr. Frank R. Spencer, Boulder, Colo., read a paper on "Importance of the Early Diagnosis and Treatment of Laryngeal Tuberculosis." Discussed by Drs. Hill Hastings, Los Angeles; Joseph C. Beck, Chicago; W. V. Mullin, Cleveland; I. D. Bronfin, Sanatorium, Colo., and Frank R. Spencer, Boulder, Colo.

THURSDAY, APRIL 22—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman.

Dr. Arthur W. Proetz, St. Louis, read a paper on "Displacement Irrigation: A New Procedure in the Diagnosis and Conservative Treatment of Posterior Sinus Disease."

Dr. Greenfield Sluder, St. Louis, read a paper on "Two Factors in Catarrhal Deafness: The Lower Turbinate (Technic) and the Sphenoid Sinus (Anatomy)."

These two papers were discussed by Drs. George M. Coates, Philadelphia; George E. Shambaugh, Chicago; Robert Barclay, St. Louis; Edwin C. Ernst, St. Louis; Harold M. Hays, New York; E. Lee Myers, St. Louis; J. Addison Lea, Kansas City, Mo.; J. M. Robison, Houston, Texas; Sidney Israel, Houston, Texas; Arthur W. Proetz, St. Louis, and Greenfield Sluder, St. Louis.

Dr. Wells P. Eagleton, Newark, N. J., read a paper on "Surgical Treatment of Meningitis from Aural Origin." Discussed by Drs. E. R. Carpenter, Dallas, Texas; G. L. Richards, Boston; Hill Hastings, Los Angeles, and Wells P. Eagleton, Newark, N. J.

Dr. Hill Hastings, Los Angeles, read a paper on "Sinus and Jugular Thrombosis (Bilateral), Bilateral Ligation; Recovery; Report of Case." Discussed by Drs. George M. Coates, Philadelphia; O. Jason Dixon, Kansas City; R. H. T. Mann, Texarkana, Ark.; Sam E. Roberts, Kansas City Mo., and Hill Hastings, Los Angeles.

Dr. Horace Newhart, Minneapolis, read a paper on "The Diagnostic Ear Clinic in the Public Schools as a Factor in the Conservation of Hearing."

Drs. E. P. Fowler and Harvey Fletcher, New York, presented a paper on "Three Million Deafened School Children: Methods for Their Detection and Treatment."

These two papers were discussed by Drs. Austin A. Hayden, Chicago; Harold M. Hays, New York; Horace Newhart, Minneapolis, and Harvey Fletcher, New York.

FRIDAY, APRIL 23—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Dr. George M. Coates, Philadelphia; vice chairman, Dr. R. C. Lynch, New Orleans; secretary, Dr. W. V. Mullin, Cleveland; delegate, Dr. Burt R. Shurly, Detroit; alternate, Dr. George E. Shambaugh, Chicago; Executive Committee, Drs. George M. Coates, Philadelphia; Samuel Iglauer, Cincinnati; and Charles W. Richardson, Washington, D. C.

Dr. Horace Newhart, Minneapolis, presented an electric light appliance for the remote control by the chairman of a speaker.

Dr. Amédée Granger, New Orleans, showed slides of a device which permits greater uniformity in making roentgenograms when duplicates are desired.

The Committee on Necrology presented its report.

On motion of Dr. C. W. Richardson, Washington, D. C., duly seconded, this report was accepted, and the section stood with bowed heads for one minute in memory of the deceased members.

The Committee on Lye Legislation made its report. Dr. C. W. Richardson, Washington, D. C., the vice chairman, gave a detailed account of the work of the committee before the committees of the Senate and House at Washington.

On motion of Dr. Harold M. Hays, New York, duly seconded, the report was accepted and the committee reappointed with a vote of thanks for its work.

It was moved by Dr. Ross H. Skillern, Philadelphia, that the report of the Examining Board in Otolaryngology (read at the Wednesday afternoon session) be received and the committee reappointed. Motion seconded and carried.

The Committee on Otorhinologic Hygiene of Swimming presented its report.

Dr. Austin A. Hayden, Chicago, moved that this report be accepted, that the committee be continued and that the recommendations made by the committee be carried out on due conference with the chairman of this section. Motion seconded by Dr. Harold M. Hays, New York, and carried.

Dr. Charles W. Richardson, Washington, D. C., presented the report of the Permanent Committee on the Deaf Child:

The Permanent Committee on the Deaf Child reports progress. The activity which is shown along all lines in taking cognizance of the requirements of the young and adult deaf among the otologists of the country, since the creation of this committee, is no doubt partly due to the appointment of this committee. Through the generous action of the National Research Council, sufficient funds have been furnished to aid this committee in carrying on its research work in investigation of the physical auditory condition of the deaf. This reasearch can now be carried out along more uniform and efficient lines than was possible under voluntary effort.

Dr. Harold M. Hays, New York, moved that the report be accepted and the committee continued. Motion seconded and carried.

Dr. C. W. Richardson moved that the two committees (Committee on the Deaf Child and Committee on the Adult Deaf be separated, allowing the Permanent Committee on the Deaf Child to stand as it is, and making a second Committee on the Adult Deaf under the chairmanship of Dr. Harold M. Hays, New York. Motion seconded by Dr. Austin A. Hayden, Chicago.

After considerable discussion it was moved by Dr. Wendell C. Phillips that the work of the Committee on the Deaf Child include adventitious deafness without speech, and that adventitious deafness in children with speech be included in the work of the other committee.

This amendment was accepted by Dr. Richardson; the amendment carried, and the original motion as amended carried.

Dr. Herman J. Moersch, Rochester, Minn., read a paper on "Hysterical Dysphagia." Discussed by Drs. John B. Potts, Omaha; Dan Brannin, Dallas, Texas; E. Lee Myers, St. Louis; Charles W. Richardson, Washington, D. C., and Herman J. Moersch, Rochester, Minn.

Dr. William W. Wasson, Denver, read a paper on "The Thymus Gland." Discussed by Drs. Percy Luecke, Dallas, Texas; C. U. Moore, Portland, Ore.; H. F. Helmholz, Rochester, Minn., and William W. Wasson, Denver.

Dr. Albert D. Kaiser, Rochester, N. Y., read a paper on "Indications for Tonsillectomy in Children Based on End-Results."

Dr. Edwin S. Ingersoll, Rochester, N. Y., read a paper on "Surgical Study of Eight Thousand Tonsillectomies in Children."

Dr. F. J. Pratt, Minneapolis, read a paper on "Postoperative Results of Tonsil Operations: A Questionnaire Report."

These three papers were discussed by Drs. Hugh McCulloch, St. Louis; Roy A. Barlow, Madison, Wis.; Sam E. Roberts, Kansas City, Mo.; W. V. Mullin, Cleveland; Albert D. Kaiser, Rochester, N. Y.; Edwin S. Ingersoll, Rochester, N. Y., and F. J. Pratt, Minneapolis.

SECTION ON DISEASES OF CHILDREN

Wednesday, April 21—Morning

The meeting was called to order at 9:35 by the chairman, Dr. Clifford G. Grulee, Chicago.

Dr. V. David Greer, Houston, Texas, read a paper on "The Clinical Study of the Therapy of Pyloric Stenosis in Infants." Discussed by Drs. H. Leslie Moore, Dallas, Texas; H. F. Helmholz, Rochester, Minn.; A. Aballi, Havana, Cuba; F. W. Schlutz, Minneapolis; A. J. Scott, Los Angeles; Jules M. Brady, St. Louis; E. P. Gengenbach, Denver; Leon Velasco Blanco, Buenos Aires, Argentina; F. C. Neff, Kansas City, Mo., and V. David Greer, Houston, Texas.

Dr. Clifford G. Grulee, Chicago, read the chairman's address, entitled "Infant Feeding."

Dr. F. H. Richardson, Brooklyn, read a paper on "The Breast Feeding Demonstration and the Physician."

Dr. C. Ulysees Moore, Portland, Ore., read a paper on "Breast Feeding Problems."

Drs. J. Victor Greenebaum and A. Graeme Mitchell, Cincinnati, presented a paper on "Effects of Diet During Pregnancy on the Development of Rickets in the Offspring."

These three papers were discussed by Drs. E. J. Huenekens, Minneapolis; R. Ralph Ferguson, Chicago; M. L. Turner, Des Moines; A. J. Scott, Los Angeles; G. B. McFarland, Dallas, Texas; Charles G. Kerley, New York; F. W. Schlutz, Minneapolis; H. R. Sackett, St. Petersburg, Fla.; Floyd Clarke, Omaha; F. H. Richardson, Brooklyn; C. Ulysees Moore, Portland, Ore., and J. Victor Greenebaum, Cincinnati.

Dr. A. Aballi, Havana, Cuba, read a paper entitled "Could the Prognosis of Infantile Anemias Be Sustained Only by the Hemogram?"

Thursday, April 22—Morning

The meeting was called to order at 9 o'clock by the chairman.

Dr. F. W. Schlutz, Minneapolis, read a paper on "The Plasma Proteins in Orthostatic Albuminuria." Discussed by Dr. H. F. Helmholz, Rochester, Minn.

Dr. H. F. Helmholz, Rochester, Minn., read a paper on "Exophthalmic Goiter in Childhood." No discussion.

The following papers were read as a symposium on "Chronic Nonspecific Infections of the Lungs and Bronchi:"

Dr. John Lovett Morse, Boston: "General Introduction and Diagnosis."

Dr. William V. Mullin, Cleveland: "Relationship to Infection in Upper Respiratory Area."

Dr. Chevalier Jackson, Philadelphia: "Bronchoscopic Phases of Chronic Nonspecific Infections in the Lungs."

Dr. Joseph Brenneman, Chicago: "Medical Treatment."

Dr. Evarts A. Graham, St. Louis: "Surgical Treatment."

Friday, April 23—Morning

The meeting was called to order at 9:05 by the chairman.

The following officers were elected: chairman, Dr. Henry J. Gerstenberger, Cleveland; vice chairman, Dr. Edgar P. Copeland, Washington, D. C.; secretary, Dr. Hugh McCulloch, St. Louis; delegate, Dr. I. A. Abt, Chicago; alternate, Dr. E. J. Huenekens, Minneapolis; member of Abraham Jacobi Fund Committee, Dr. Clifford G. Grulee, Chicago; Committee on Education of Pediatrics: Drs. Julius Hess, Chicago, chairman; W. A. Mulherin, Augusta, Ga., and Frank Gengenbach, Denver, Colo.

Dr. F. C. Neff, Kansas City, Mo., presented the report for the Abraham Jacobi Fund Committee.

Dr. I. A. Abt, Chicago, spoke about a communication from Dr. J. M. Dodson, Chicago, recommending the printing of a blank to be used in periodic health examination of infants and children. A committee was to be appointed by the chairman to consider the matter proposed by Dr. Dodson.

Dr. H. F. Helmholz of the Executive Committee presented the following resolutions:

> *Resolved*, That the Section on Diseases of Children of the American Medical Association extend to the Dallas County Medical Society its most sincere thanks for the many courtesies extended to its members.
>
> Second, that the Section on Diseases of Children of the American Medical Association extend its thanks to Dr. Leslie Moore and his local committee for the true Southern hospitality that we have enjoyed here in Dallas.
>
> Third, that the Section on Diseases of Children of the American Medical Association send greetings to the Medical Association of the Argentine Republic and the Pediatric Society of Buenos Aires, with the hope that this auspicious beginning of relationship be cemented into a more firm friendship.
>
> Fourth, that it express to our invited guest, Dr. A. Aballi of Havana, Cuba, and to Dr. Leon Velasco Blanco of Buenos Aires, Argentine Republic, its appreciation of the honor they have done us in coming here, and extend to them our thanks for the part they have played in our scientific program.

The resolution of the Executive Committee was moved for adoption by Dr. G. H. Fellman, Milwaukee, seconded by Dr. M. L. Turner, Des Moines, Iowa, and unanimously carried. Adoption of the Executive Committee report as a whole was moved by Dr. I. A. Abt, Chicago, seconded by Dr. Frank Gengenbach, Denver, and carried unanimously.

Dr. Leon Velasco Blanco, Buenos Aires, Argentina, read a paper entitled "Contribution to the Study of Meningeal Hemorrhage." No discussion.

Dr. P. H. Sylvester, Boston, read a paper on "Twenty-Five Years of Congenital Syphilis: A Comparative and Statistical Study." No discussion.

Drs. I. A. Abt and Alfred A. Strauss, Chicago, presented a paper on "Meckel's Diverticulum as a Cause of Intestinal

Hemorrhage: Report of Five Cases." Discussed by Drs. L. D. Hill, San Antonio, Texas; C. Ulysses Moore, Portland, Ore.; J. B. Stone, Richmond, Va.; H. F. Helmholz, Rochester, Minn.; F. C. Neff, Kansas City, Mo.; F. W. Schlutz, Minneapolis, and Alfred A. Strauss, Chicago.

Drs. H. J. Gerstenberger and John D. Nourse, Cleveland, presented a paper on "The Prevention of Rickets in Premature Infants." No discussion.

Dr. Stafford McLean, New York, read a paper on "The End-Results of Specific Serum Therapy in Sporadic Meningococcus Meningitis in Infancy and Early Childhood." No discussion.

Drs. P. C. Jeans and M. L. Floyd, Iowa City, presented a paper on "Paranasal Sinusitis as a Cause of So-Called Alimentary Intoxication." Discussed by Drs. E. C. Mitchell, Memphis, Tenn.; John J. Shea, Memphis, Tenn.; John L. Morse, Boston; H. J. Gerstenberger, Cleveland; Jules M. Brady, St. Louis; H. F. Helmholz, Rochester, Minn., and M L. Floyd, Iowa City.

Drs. E. J. Huenekens and L. C. Rigler, Minneapolis, presented a paper on "Osteomyelitis Variolosa." Discussed by Dr. O E. Egbert, El Paso.

Dr. J. D. Boyd, Iowa City, read a paper on "The Use of Standard Diet Formulas in the Management of Juvenile Diabetes Mellitus." Discussed by Drs. William H. Olmsted, St. Louis; M. L. Turner, Des Moines, Iowa, and J. D. Boyd, Iowa City.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

Wednesday, April 21—Morning

The meeting was called to order at 9:15 by the chairman, Dr. Thomas Ordway, Albany, N. Y.

Dr. G. Canby Robinson, Nashville, Tenn., read a paper on "The Measurement of the Cardiac Output and Its Variations."

Drs. A. A. James, N. B. Laughton and A. Bruce Macallum, London, Ont., presented a paper on "The Antipressor Fraction in Liver Tissue and Its Physiologic Action."

Dr. Ralph H. Major, Kansas City, Kan., read a paper on "The Action of Hepatic Extract in Hypertension."

Dr. George E. Brown, Rochester, Minn., read a paper on "Treatment of the Peripheral Vascular Disturbances of the Extremities."

Dr. Joseph L. Miller, Chicago, read a paper on "The Visceral Manifestations of Diffuse Cardiovascular Hypertensive Disease."

These five papers were discussed by Drs. J. N. Hunsberger, Norristown, Pa.; E. C. Thrash, Atlanta, Ga.; J. H. Pratt, Boston; Walter Shropshire, Yoakum, Texas; Emmet F. Horine, Louisville, Ky.; Wilbur A. Baker, Kansas City, Mo.; I. I. Lemann, New Orleans, La., and G. C. Robinson, Nashville, Tenn.

Thursday, April 22—Morning

The meeting was called to order at 9:10 by the secretary, Dr. Norman M. Keith, Rochester, Minn.

Dr. Thomas Ordway, Albany, N. Y., read the chairman's address, entitled "Conservative Therapeutics."

Dr. G. S. Amsden, Albany, N. Y., read a paper on "Psychopathology in General Practice." No discussion.

Dr. J. B. Collip, Edmonton, Alta., read a paper on "The Therapeutic Value of the Parathyroid Hormone." Discussed by Drs. Robert Dinsmore, Cleveland; Norman M. Keith, Rochester, Minn.; Martin B. Tinker, Ithaca, N. Y.; Orlando H. Petty, Philadelphia; Frank C. Neff, Kansas City, Mo., and J. B. Collip, Edmonton, Alta.

Dr. Walter M. Bartlett, Boston, read a paper on "Protein Requirement in Children. Discussed by Drs. John R. Williams, Rochester, N. Y.; Norman M. Keith, Rochester, Minn., and Walter M. Bartlett, Boston.

Drs. Martin B. Tinker and Henry B. Sutton, Ithaca, N. Y., presented a paper on "The Inefficiency of Most Commonly Used Antiseptics in Medicine and Surgery. Discussed by Drs. Hugh Young, Baltimore, and Martin B. Tinker, Ithaca, N. Y.

Dr. Walton Forest Dutton, Amarillo, Texas, read a paper on "Chronic Hereditary and Familial Hemolytic Jaundice with Splenomegaly and Hepatomegaly." No discussion.

Dr. K. K. Chen, Madison, Wis., read a paper on "The Action and Clinical Use of Ephedrine, an Alkaloid Isolated from the Chinese Drug Mahuang." Discussed by Drs. George E. Brown, Rochester, Minn.; A. P. Munsch, St. Louis; Ralph H. Major, Kansas City, Kan.; Joseph L. Miller, Chicago; Dr. Clyde Brooks, Tuscaloosa, Ala.; J. I. Johnston, Pittsburgh; Julien E. Benjamin, Cincinnati, and K. K. Chen, Madison, Wis.

Dr. George E. Brown, Rochester, Minn., moved that the appointment of Dr. Roger I. Lee, Boston, be authorized as alternate delegate to the House of Delegates of the American Medical Association from the Section on Pharmacology and Therapeutics. Motion seconded by Dr. Ralph Major, Kansas City, Kan., and carried.

Friday, April 23—Morning

The meeting was called to order at 9:10 by the chairman.

The following officers were elected: chairman, Dr. W. de B. MacNider, Chapel Hill, N. C.; vice chairman, Dr. Roger Lee, Boston; secretary, Dr. Norman M. Keith, Rochester, Minn.; delegate, Dr. Paul D. White, Boston; alternate, Dr. Cary Eggleston, New York; Executive Committee: Dr. Paul D. White, Boston; Dr. Thomas Ordway, Albany, N. Y., and Dr. W. de B. MacNider, Chapel Hill, N. C.

Dr. Albert A. Epstein, New York, read a paper on "Thyroid Therapy and Thyroid Tolerance in Chronic Nephrosis." Discussed by Drs. Norman M. Keith, Rochester, Minn., and Albert A. Epstein, New York.

Dr. Samuel H. Watson, Tucson, Ariz., read a paper on "The Use and Abuse of Heliotherapy in Tuberculosis." Discussed by Drs. Charles E. Sevier, Colorado Springs, Colo.; I. D. Bronfin, Sanatorium, Colo.; Felix Baum, Denver; O. E. Egbert, El Paso, Texas; Victor Randolph, Phoenix, Ariz.; C. D. Spivak, Denver, and Samuel H. Watson, Tucson, Ariz.

Dr. H. Z. Giffin, Rochester, Minn., read a paper on "The Treatment of Polycythemia Vera." Discussed by Drs. C. L. Stealy, San Diego, Calif.; Joseph H. Pratt, Boston; J. A. McIntosh, Memphis, Tenn., and H. Z. Giffin, Rochester, Minn.

Drs. Fred M. Smith, Verne C. Graber and George H. Miller, Iowa City, presented a paper on "Action of Euphyllin in Cardiac Failure Associated with Arteriosclerosis." No discussion.

Dr. Emil Bogen, Los Angeles, read a paper on "Arachnidism, a Study in Spider Poisoning." No discussion.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Wednesday, April 21—Afternoon

The meeting was called to order at 2:15 by the chairman, Dr. Harry J. Corper, Denver.

Dr. Micheal G. Wohl, Omaha, read a paper on "Avitaminosis with Symptoms and Lesions of Beriberi Occurring During the Course of Diabetes: Report of Case." Discussed by Drs. Orlando H. Petty, Philadelphia; R. G. Hoskins, Columbus; Scott R. Edwards, Miami Beach, Fla.; Peter Bassoe, Chicago, and Michael G. Wohl, Omaha.

Dr. A. C. Nickel, Rochester, Minn., read a paper on "Localization in Animals of Bacteria Isolated from Foci of Infection." Discussed by Drs. Russell L. Haden, Kansas City, Mo.; Clyde Brooks, University, Ala.; William W. Duke, Kansas City, Mo.; James H. Huddelson, New York, and A. C. Nickel, Rochester, Minn.

Drs. John V. Barrow and E. L. Armstrong, Los Angeles, presented a paper on "The Etiology and Pathology of Arthritis Deformans as Forecast by Clinical Manifestations." Discussed by Drs. W. H. Olds, Los Angeles; Lloyd Mills, Los Angeles, and John V. Barrow, Los Angeles.

Dr. William W. Duke, Kansas City, Mo., read a paper on "Estimation of Circulating Hemoglobin Volume, a Simple, Practical Method for Clinical Purposes." Discussed by Drs. Clyde Brooks, University, Ala.; W. F. Singer, Pueblo, Colo., and William W. Duke, Kansas City, Mo.

Dr. James Herbert Mitchell, Chicago, read a paper on "Menace of the Slightly Positive Wassermann Reaction." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; H. J. Corper, Denver; Michael G. Wohl, Omaha; Ralph E. Duncan, Kansas City, Mo.; C. E. Roderick, Battle Creek, Mich.; J. J. Moore, Chicago, and James Herbert Mitchell, Chicago.

Dr. Clyde Brooks, University, Ala., read a paper on "Conduction and Contraction of Cardiac Musculature in Water Rigor." Discussed by Drs. F. T. Rogers, Dallas, Texas; C. I. Reed, Dallas, Texas, and Clyde Brooks, University, Ala.

Dr. Josiah J. Moore, Chicago, secretary, presented the list of applicants for associate fellowships and moved its adoption. Motion seconded and unanimously carried.

Drs. Frank B. Young, Gering, Neb., and A. L. Cooper, Scottsbluff, Neb., presented a paper on "Evidences of Diseases as Shown in Fossil and Prehistoric Remains; Paleopathology." Discussed by Drs. H. W. Orr, Lincoln, Neb.; J. W. Draper, New York; E. S. Blaine, Chicago, and Frank B. Young, Gering, Neb.

Thursday, April 22—Afternoon

The meeting was called to order at 2:10 by the chairman.

Dr. Harry J. Corper, Denver, read the chairman's address, entitled "Absorption from Lower Respiratory Tract."

Dr. Mary E. Lapham, Highlands, N. C., read a paper on "Aspergillosis of the Lungs and Its Association with Tuberculosis." Discussed by Drs. Henry C. Sweany, Chicago; Kenneth M. Lynch, Dallas, Texas; Aldo Castellani, New Orleans, and Mary E. Lapham, Highlands, N. C.

Dr. Esmond R. Long, Chicago, read a paper on "Specific Necrosis in the Infectious Granulomas." Discussed by Drs. Harry J. Corper, Denver; Henry C. Sweany, Chicago, and Esmond R. Long, Chicago.

Dr. Henry C. Sweany, Chicago, read a paper on "Mutation Forms of the Tubercle Bacillus." Discussed by Drs. Esmond R. Long, Chicago; Harry J. Corper, Denver, and Henry C. Sweany, Chicago.

Dr. Aldo Castellani, New Orleans, read a paper on "The Importance of Symbiosis or Close Association of Different Species of Organisms in the Production of Certain Biochemical Phenomena and in the Causation of Certain Diseases and Certain Symptoms of Disease." No discussion.

Dr. J. A. McIntosh, Memphis, Tenn., read a paper on "A Study of Granuloma Inguinale." Discussed by Drs. Kenneth M. Lynch, Dallas, Texas; Samuel M. Peck, New York, and J. A. McIntosh, Memphis, Tenn.

Friday, April 23—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Dr. R. G. Hoskins, Columbus, Ohio; vice chairman, Dr. H. R. Wahl, Kansas City, Mo.; secretary, Dr. J. J. Moore, Chicago; delegate, Dr. D. J. Davis, Chicago; alternate, Dr. J. J. Moore, Chicago.

Drs. F. W. Hartman, Adolph Bolliger and H. P. Doub, Detroit, presented a paper on "Functional Studies Throughout the Course of Roentgen-Ray Nephritis in Dogs." Discussed by Drs. Norman M. Keith, Rochester, Minn.; J. W. Sherrill, La Jolla, Calif.; V. C. Myers, Iowa City, and F. W. Hartman, Detroit.

Drs. Frank Hinman and Francis H. Redewill, San Francisco, presented a paper on "The Mechanism of Pyelovenous Backflow." No discussion.

Dr. Francis Carter Wood, New York, presented a paper on "The Use of Colloidal Lead in the Treatment of Cancer." Discussed by Drs. George T. Caldwell, Dallas, Texas; E. C. Ernst, St. Louis, and Francis Carter Wood, New York.

Dr. Albert C. Broders, Rochester, Minn., read a paper on "Grading of Carcinoma and Its Practical Application." Discussed by Drs. J. Shelton Horsley, Richmond, Va., and W. C. Hueper, Chicago.

Dr. O. Jason Dixon, Kansas City, Mo., read a paper on "The Pathologic Findings in Cavernous Sinus Thrombosis as a Guide to the Diagnosis, Prognosis and Treatment." No discussion.

SECTION ON NERVOUS AND MENTAL DISEASES

Wednesday, April 21—Morning

The meeting was called to order at 9:15 by the chairman, Dr. James B. Ayer, Boston.

In the absence of Dr. Edwin G. Zabriskie, New York, the chairman appointed Dr. William House, Portland, Ore., to serve on the Executive Committee.

Dr. James B. Ayer, Boston, read the chairman's address, entitled "Analysis of Spinal Fluid Tests."

Dr. James H. Huddleson, New York, read a paper on "The Connotation of Constitutional Psychopathic Inferiority Without Psychoses: A Study of Five Hundred Diagnoses." Discussed by Drs. William House, Portland, Ore.; Sidney I. Schwab, St. Louis; Theodore Diller, Pittsburgh, and James H. Huddleson, New York.

Dr. Franklin G. Ebaugh, Denver, read a paper on "Neuropsychiatric Aspects of Chorea in Children." Discussed by Drs. George A. Moleen, Denver; Roy P. Forbes, Denver; Theodore Diller, Pittsburgh; Sidney I. Schwab, St. Louis, and Franklin G. Ebaugh, Denver.

Dr. Theodore Diller, Pittsburgh, read a paper on "The Social and Economic Aspects of Nervous and Mental Diseases." Discussed by Drs. J. S. Wilkins, Hot Springs, Ark.; Carl D. Camp, Ann Arbor, Mich.; Frank S. White, Wichita Falls, Texas; Gilbert E. Seaman, Milwaukee, and Theodore Diller, Pittsburgh.

Dr. Sidney I. Schwab, St. Louis, read a paper on "Cardiac Symptoms in Emotional Conflicts." Discussed by Drs. L. J. Manhoff, San Antonio, Texas; Lloyd Mills, Los Angeles; A. L. Skoog, Kansas City, Mo.; Theodore Diller, Pittsburgh, and Sidney I. Schwab, St. Louis.

Dr. M. S. Gregory, Oklahoma City, read a paper on "Some Infantile Factors in the Etiology of Hysteria." Discussed by Drs. Carl D. Camp, Ann Arbor, Mich., and M. S. Gregory, Oklahoma City.

Thursday, April 22—Morning

The meeting was called to order at 9:15 by the chairman.

The following officers were elected: chairman, William House, Portland, Ore.; vice chairman, George W. Hall, Chicago; secretary, Lewis J. Pollock, Chicago; delegate, Tom B. Throckmorton, Des Moines, Iowa; alternate, Edward Delehanty, Denver.

Dr. Tom. B. Throckmorton, Des Moines, Iowa, read a paper on "Glioma of the Pons Varolii Simulating a Frontomotor Tumor." Discussed by Drs. George A. Moleen, Denver; Peter Bassoe, Chicago; A. L. Skoog, Kansas City, Mo., and Tom. B. Throckmorton, Des Moines, Iowa.

Dr. Walter F. Schaller, San Francisco, read a paper on "An Unusual Case of Subacute Combined Cord Degeneration." Discussed by Drs. W. A. Jones, Minneapolis; George W. Hall, Chicago; Lewis J. Pollock, Chicago; George A. Moleen, Denver; A. L. Skoog, Kansas City, Mo.; James B. Ayer, Boston, and Walter F. Schaller, San Francisco.

Dr. A. L. Skoog, Kansas City, Mo., read a paper on "Neurologic Manifestations in Pernicious Anemia: A New Conception Relative to Etiology." Discussed by Drs. Walter F. Schaller, San Francisco, and A. L. Skoog, Kansas City, Mo.

Dr. Harry L. Parker, Rochester, Minn., read a paper on "Aneurysms of the Cerebral Vessels: The Clinical Manifestations and Pathology." Discussed by Drs. George W. Hall, Chicago; William House, Portland, Ore.; Edwin G. Zabriskie, New York, and Harry L. Parker, Rochester, Minn.

Dr. Walter D. Shelden, Rochester, Minn., read a paper on "Secondary Tumors of the Brain." Discussed by Drs. Peter Bassoe, Chicago; William House, Portland, Ore.; George W. Hall, Chicago; A. L. Skoog, Kansas City, Mo.; Harry L. Parker, Rochester, Minn., and Walter D. Sheldon, Rochester, Minn.

Friday, April 23—Morning

A joint meeting was held with the Section on Surgery, General and Abdominal. For a report of the proceedings, see the minutes of that section.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Wednesday, April 21—Morning

The meeting was called to order at 9:10 by the chairman, Dr. Fred Wise, New York.

The chairman appointed Dr. Howard Morrow, San Francisco, to serve on the Executive Committee in the place of Dr. Harold N. Cole, Cleveland, who was absent.

Dr. Fred Wise, New York, read the chairman's address, entitled "Progress in the Treatment of Skin Diseases."

Drs. J. R. Driver, John A. Gammel and L. J. Karnosh, Cleveland, presented a paper on "The Use of Malarial Infection in the Treatment of Syphilis of the Central Nervous System." Discussed by Drs. William H. D. Goeckerman, Rochester, Minn.; Hans H. Reese, Madison, Wis., and J. R. Driver, Cleveland.

Dr. William H. Guy, Pittsburgh, read a paper on "Clinical Notes on the Incidence and Treatment of Interstitial Keratitis in Congenital Syphilis." Discussed by Drs. F. J. Eichenlaub, Washington, D. C.; John E. Lane, New Haven, Conn.; I. L. McGlasson, San Antonio, Texas; N. N. Epstein, Cleveland, and William H. Guy, Pittsburgh.

Drs. N. N. Epstein and J. E. Rauschkolb, Cleveland, presented a paper on "Further Observations on the Rose Bengal Test for Liver Function, with Particular Reference to Its Use in Therapy of Syphilis." Discussed by Drs. William J. Kerr, San Francisco; William H. D. Goeckerman, Rochester, Minn.; J. E. Rauschkolb, Cleveland; E. A. Purdum, Hot Springs, Ark., and N. N. Epstein, Cleveland.

Drs. Fred M. Jacob and L. G. Beinhauer, Pittsburgh, presented a paper on "Sodium Thiosulphate in Wassermann-Fast Syphilis: A Preliminary Report." Discussed by Drs. William H. Guy, Pittsburgh; William L. McBride, Kansas City, Mo.; R. E. Duncan, Kansas City, Mo., and Fred M. Jacob, Pittsburgh.

Drs. Jerome Kingsbury and S. M. Peck, New York, presented a paper on "Intravenous Administration of Antimony and Potassium Tartrate in Phagedenic Ulcerations of the Genitals." Discussed by Drs. Aldo Castellani, New Orleans; Howard Fox, New York, and S. M. Peck, New York.

Dr. H. G. Miskjian, Cleveland, read a paper on "An Efficient Treatment of Chancroidal Buboes: Injections of Mencière's Solution." Discussed by Drs. Herman L. Kretschmer, Chicago; J. E. Rauschkolb, Cleveland; Abraham Mattes, New Orleans, and H. G. Miskjian, Cleveland.

Thursday, April 22—Morning

The meeting was called to order at 9:10 by the chairman.

The secretary read the following report from the chairman of the committee appointed to study the subject of legislation in regard to injurious effects of hair dyes and cosmetics:

> Since the last meeting of this section there has been no official meeting of this committee. The committee has been in correspondence with its different members, however, with the American Medical Association central office and with Dr. Woodward.
>
> We have finally succeeded in gathering together a large number of reports from various parts of the country in regard to the injurious effects of these preparations.
>
> We then felt that it was necessary to find out from the literature what others had reported and also what legislation had thus far been passed, especially in some of the foreign countries where this study has been more thorough in its character.
>
> We were unable to get any grant for this purpose until a meeting of the Trustees in February, at which time a grant of $1,000 was given to our committee.
>
> Since then Dr. Woodward has been attempting to find the proper person who would be competent to make this investigation of the literature. We are hoping that this summer it can be carried out, most of it, of course, having to be done at the Surgeon-General's Library in Washington.
>
> In the meantime, we have nothing further to report except progress.
>
> Respectfully submitted.
>
> Harold N. Cole, Chairman.
> Francis E. Senear.
> Udo J. Wile.

Dr. Harry R. Foerster, Milwaukee, read a paper on "Sporotrichosis, an Occupational Dermatosis."

Dr. Isaac R. Pels, Baltimore, read a paper on "An Unusual Eruption Due to an Organism of the Sporotrichum Group."

These two papers were discussed by Drs. Aldo Castellani, New Orleans; Earl D. Crutchfield, Galveston, Texas; Howard King, Nashville, Tenn.; Harry R. Foerster, Milwaukee, and Isaac R. Pels, Baltimore.

Dr. Howard Fox, New York, read a paper on "Granuloma Inguinale: Its Prevalence in the United States." Discussed by Drs. Earl D. Crutchfield, Galveston, Texas; S. M. Peck, New York; Jeffrey C. Michael, Houston, Texas; I. L. McGlasson, San Antonio, Texas; Aldo Castellani, New Orleans, and Howard Fox, New York.

Drs. Joseph V. Klauder and M. J. Harkins, Philadelphia, presented a paper on "A Distinctive and Severe Form of Erysipeloid Among Fish Handlers: Report of Clinical and Laboratory Studies; Demonstration of the Bacillus of Swine Erysipelas."

Dr. I. L. McGlasson, San Antonio, Texas, read a paper on "Recurrent Erysipelas: Report of Cases."

These two papers were discussed by Drs. William H. Mook, St. Louis; Udo J. Wile, Ann Arbor, Mich.; Frederick D. Weidman, Philadelphia, and Joseph V. Klauder, Philadelphia.

Dr. Jeffrey C. Michael, Houston, Texas, read a paper on "Critical Investigation of the End-Products of Protein Metabolism in Eczema and Kindred Disorders." Discussed by Drs. Walter J. Highman, New York, and Samuel Ayers, Jr., Los Angeles.

Friday, April 23—Morning

The meeting was called to order at 9:15 by the chairman.

The following officers were elected: chairman, Dr. James Herbert Mitchell, Chicago; vice chairman, Dr. Frederick D. Weidman, Philadelphia; secretary, Dr. William H. Guy, Pittsburgh; delegate, Dr. Howard Fox, New York; alternate, Dr. Otto H. Foerster, Milwaukee.

Dr. John E. Lane, New Haven, Conn., brought up the question of continuing the scientific exhibit.

Dr. I. L. McGlasson, San Antonio, Texas, chairman of the committee, reported that one exhibitor had received a silver medal, and that another had received honorable mention, which he thought justified continuing the exhibit. Sufficient money had been collected to defray the expenses for this year, and a small balance to apply on next year's exhibit.

Dr. John E. Lane, New Haven, Conn., moved that the exhibit be continued, and that the appointment of a committee be left to the chairman, and the chairman of the Committee on Exhibit.

Motion seconded by Dr. William H. Guy, Pittsburgh, and unanimously carried.

Drs. George M. MacKee and J. J. Eller, New York, presented a paper on "Roentgen-Ray Idiosyncrasy." Discussed by Drs. I. L. McGlasson, San Antonio, Texas; F. W. Cregor, Indianapolis; John E. Lane, New Haven, Conn.; Henry J. Ullmann, Santa Barbara, Calif.; William H. Guy, Pittsburgh; Jeffrey C. Michael, Houston, Texas; Samuel Ayers, Jr., Los Angeles; J. J. Eller, New York, and George M. MacKee, New York.

Dr. William H. D. Goeckerman, Rochester, Minn., read a paper on "Bullous Ichthyosiform Erythroderma: Report of Two Cases." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; F. W. Cregor, Indianapolis, and William H. D. Goeckerman, Rochester, Minn.

Dr. Francis E. Senear, Chicago, read a paper on "Progressive and Recurrent Dermatofibroma (Darier)." Discussed by Drs. Edward A. Oliver, Chicago; Frederick D. Weidman, Philadelphia, and Francis E. Senear, Chicago.

Drs. Frederick D. Weidman, Philadelphia, and Loren W. Shaffer, Detroit, presented a paper on "Calcification of the Epiderm and Other Structures of the Skin in Connection with Widespread Bone Resorption." Discussed by Drs. Joseph V. Klauder, Philadelphia; W. S. Thomas, Clifton Springs, N. Y., and Frederick D. Weidman, Philadelphia.

Dr. Walter J. Highman, New York, read a paper on "Some Aspects of Skin Histopathology." Discussed by Drs. Fredreick D. Weidman, Philadelphia; Fenton B. Turck, New York, and Walter J. Highman, New York.

Dr. L. M. Wieder, Ann Arbor, Mich., read a paper on "The Juvenile Type of Acanthosis Nigricans." Discussed by Drs. Fred Wise, New York; Udo J. Wile, Ann Arbor, Mich., and L. M. Wieder, Ann Arbor, Mich.

Dr. B. Barker Beeson, Chicago, read a paper on "Granulosis Rubra Nasi (Jadassohn): Report of Case." Discussed by Drs. John E. Lane, New Haven, Conn.; Walter J. Highman, New York, and B. Barker Beeson, Chicago.

Dr. Mitchell appointed, as a committee on exhibits, Drs. Fred D. Weidman, Philadelphia, chairman; F. J. Eichenlaub, Washington, D. C., and Clark W. Finnerud, Chicago.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

WEDNESDAY, APRIL 21—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Matthias Nicoll, Jr., Albany, N. Y.

Dr. J. J. Durrett, Memphis, Tenn., read a paper on "Some Problems in Southern Municipal Health Work." Discussed by Drs. A. H. Flickwir, Houston, Texas; A. T. McCormack, Louisville, Ky.; C. W. Goddard, Austin, Texas; W. S. Leathers, Nashville, Tenn., and J. J. Durrett, Memphis, Tenn.

Dr. Matthias Nicoll, Jr., Albany, N. Y., read the chairman's address, entitled "Boundaries of the Public Health Field."

Dr. B. F. Royer, Philadelphia, read a paper on "Trachoma." Discussed by Drs. A. T. McCormack, Louisville, Ky.; E. L. Spence, Kennett, Mo., and B. F. Royer, Philadelphia.

Dr. E. L. Bishop, Nashville, Tenn., read a paper on "The Sanitary Officer and County Health Work."

Dr. P. W. Covington, Salt Lake City, read a paper on "Rural Sanitation."

These two papers were discussed by Drs. A. T. McCormack, Louisville, Ky.; D. T. Bowden, Oklahoma City; W. S. Leathers, Nashville, Tenn.; E. L. Bishop, Nashville, Tenn., and P. W. Covington, Salt Lake City.

THURSDAY, APRIL 22—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman.

Dr. James Stewart, Jefferson City, Mo., read a paper on "Public Health Aspects of Quackery." Discussed by Drs. G. S. Luckett, Santa Fe, N. M.; I. D. Rawlings, Springfield, Ill.; T. W. Buford, Minter, Texas, and James Stewart, Jefferson City, Mo.

Dr. Mazyck P. Ravenel, Columbia, Mo., read a paper on "The Trend of Public Health Work: Is it Eugenic or Dysgenic?" Discussed by Drs. John A. Ferrell, New York; G. M. Anderson, Cheyenne, Wyo.; A. S. Garrett, Weatherford, Texas; H. I. Gosline, Dallas, Texas, and Mazyck P. Ravenel, Columbia, Mo.

Dr. G. S. Luckett, Sante Fe, N. M., read a paper on "Relationship of the Practicing Physician to the Public Health Program." Discussed by Drs. G. M. Anderson, Cheyenne, Wyo.; Carl Puckett, Oklahoma City, and G. S. Luckett, Sante Fe, N. M.

Dr. Mary Evelyn Brydon, Richmond, Va., read a paper on "The Family Physician's Place in Inspection of School Children." Discussed by Drs. Winnie M. Sanger, Oklahoma City; H. I. Gosline, Dallas, Texas; F. J. Underwood, Jackson, Miss., and Mary Evelyn Brydon, Richmond, Va.

Dr. Wilmer R. Batt, Washington, D. C., read a paper entitled "Every State in the Registration Area Before 1930." No discussion.

FRIDAY, APRIL 23—AFTERNOON

The meeting was called to order at 2 o'clock by Dr. H. O. Sappington, Austin, Texas.

Dr. W. L. Aycock, Boston, read a paper on "The Epidemiology of Poliomyelitis with Reference to Its Mode of Spread." Discussed by Drs. J. P. Leake, Washington, D. C.; W. L. Holt, Little Rock, Ark.; I. D. Rawlings, Springfield, Ill.; A. C. Nickel, Rochester, Minn.; W. F. Draper, Washington, D. C., and W. L. Aycock, Boston.

Dr. J. W. Tappan, El Paso, Texas, read a paper on "Protective Health Measures on the United States-Mexico Border." Discussed by Drs. Felix P. Miller, El Paso, Texas; Malone Duggan, La Feria, Texas; Oscar Dowling, Shreveport, La.; L. H. Martin, Fort Worth, Texas, and J. W. Tappan, El Paso, Texas.

The following officers were elected: chairman, Dr. W. F. Draper, Washington, D. C.; vice chairman, Dr. I. D. Rawlings, Springfield, Ill.; secretary, Dr. E. L. Bishop, Nashville, Tenn.; alternate delegate, Dr. George H. Bigelow, Boston.

SECTION ON UROLOGY

WEDNESDAY, APRIL 21—AFTERNOON

The meeting was called to order at 2:10 by the chairman, Dr. B. A. Thomas, Philadelphia.

The chairman appointed Dr. Robert V. Day, Los Angeles, to serve on the Executive Committee in the place of Dr. John T. Geraghty, deceased.

Dr. A. J. Scholl, Jr., Los Angeles, read a paper on "Postnuptial Urinary Infection."

Dr. Winfield Scott Pugh, New York, read a paper on "Stricture of the Female Urethra."

These two papers were discussed by Drs. W. E. Stevens, San Francisco; W. F. Braasch, Rochester, Minn.; Victor G. Vecki, San Francisco; Herman L. Kretschmer, Chicago; Bransford Lewis, St. Louis; T. Leon Howard, Denver; Alfred I. Folsom, Dallas, Texas, and W. S. Pugh, New York.

Dr. Russell A. Hennessey, Memphis, Tenn., read a paper on "Leukoplakia of the Bladder."

Dr. D. K. Rose, St. Louis, read a paper on "Cystometric Determination of Bladder Pressure—Presentation of Instrument."

These two papers were discussed by Drs. George R. Livermore, Memphis, Tenn.; Evarts A. Graham, St. Louis; Daniel N. Eisendrath, Chicago; W. E. Stevens, San Francisco; J. L. Morgan, Memphis, Tenn.; Herman L. Kretschmer, Chicago; W. F. Braasch, Rochester, Minn.; Russell A. Hennessey, Memphis, Tenn., and D. K. Rose, St. Louis.

Dr. Maximilian Stern, New York, read a paper on "Resection of Obstructions at the Vesical Orifice: A New Cystoscopic Instrument Employing a Cutting Current Capable of Operation in a Water Medium."

Drs. Harry W. Martin and Rachel E. Arbuthnot, Los Angeles, presented a paper on "Spinal Anesthesia: A Review of More than Six Thousand Cases in the Los Angeles General Hospital, with Especial Consideration for Urologic Operations."

These two papers were discussed by Drs. Robert V. Day, Los Angeles; A. C. Gilbert, Dallas, Texas; W. W. Babcock, Philadelphia; Arthur L. Chute, Boston; Albert E. Goldstein, Baltimore, and Harry W. Martin, Los Angeles.

The secretary said that he had received a letter from Dr. Walter E. Brunet, secretary of the American Social Hygiene Association, in regard to establishing a scientific exhibit on gonorrhea, stating that if the Section on Urology did not care to do this, the matter would be taken up by the American Social Hygiene Association.

Dr. Robert V. Day, Los Angeles, moved that the chairman appoint a committee of three to investigate the matter of having a scientific exhibit by the section and to report on Friday with recommendation. Motion seconded and carried.

The chairman appointed a committee consisting of Drs. W. E. Stevens, San Francisco; Budd Corbus, Chicago, and Alfred I. Folsom, Dallas, Texas.

Thursday, April 22—Afternoon

The meeting was called to order at 2:10 by the chairman.

Dr. B. A. Thomas, Philadelphia, read the chairman's address, entitled "Influence of Urology on Longevity."

Dr. W. F. Braasch, Rochester, Minn., read a paper on "Prognosis in Chronic Pyelonephritis." Discussed by Drs. C. E. Burford, St. Louis; Daniel N. Eisendrath, Chicago; Hugh H. Young, Baltimore; Herman L. Kretschmer, Chicago; Albert E. Goldstein, Baltimore; Abraham Mattes, New Orleans; Alfred I. Folsom, Dallas, Texas and W. F. Braasch, Rochester, Minn.

The following papers were read as a symposium on "The Treatment of Bladder Carcinoma":

Dr. E. Starr Judd, Rochester, Minn: "Treatment of Carcinoma of the Bladder by Radical Surgery."

Dr. Alfred I. Folsom, Dallas, Texas: "Radium Treatment of Carcinoma of the Bladder."

Dr. Charles Alexander Waters, Baltimore: "Deep Roentgen-Ray Therapy in Bladder Tumors."

Dr. Arthur L. Chute, Boston: "Ureteral Transplantation in Bladder Carcinoma: Technic and Utility."

These four papers were discussed by Drs. Bransford Lewis, St. Louis; Daniel N. Eisendrath, Chicago; Nelse F. Ockerblad, Kansas City, Mo.; James F. Percy, Los Angeles; Howard L. Cecil, Dallas, Texas; George Gilbert Smith, Boston; Robert V. Day, Los Angeles; A. J. Crowell, Charlotte, N. C.; T. Leon Howard, Denver; P. E. McCown, Indianapolis, and Arthur L. Chute, Boston.

Friday, April 23—Afternoon

The meeting was called to order at 2:10 by the chairman.

The following officers were elected: chairman, Dr. George Gilbert Smith, Boston; vice chairman, Dr. Alfred I. Folsom, Dallas, Texas; secretary, Dr. Hermon C. Bumpus, Rochester, Minn.

Dr. W. E. Stevens, San Francisco, reported that the committee had discussed with the members of the section the question of a scientific exhibit on gonorrhea, and that the consensus was that the section should cooperate with a committee from the American Social Hygiene Association. The committee so recommended.

Dr. W. E. Stevens, San Francisco, moved that the chairman discharge the temporary committee and appoint a permanent committee to cooperate with the American Social Hygiene Association, one member to be from New York. Motion seconded and carried.

The chairman appointed a committee consisting of Drs. Francis R. Hagner, Washington, D. C., chairman; E. L. Keyes, New York, and Alexander Randall, Philadelphia.

Dr. Clinton K. Smith, Kansas City, Mo., read a paper on "A Ureteropyelographic Postmortem Study of Infants and Children: Its Relation to Urinary Pathology in Adults and Practical Application to Urology in Children."

Dr. Abraham Mattes, New Orleans, read a paper on "Bilateral Pyelo-Ureterograms."

These two papers were discussed by Drs. W. E. Stevens, San Francisco; Alfred I. Folsom, Dallas, Texas; Albert E. Goldstein, Baltimore; Nelse F. Ockerblad, Kansas City, Mo.; I. G. Duncan, Memphis, Tenn.; Daniel N. Eisendrath, Chicago; W. J. Wallace, Oklahoma City; Herman L. Kretschmer, Chicago; A. J. Crowell, Charlotte, N. C.; Robert V. Day, Los Angeles; George R. Livermore, Memphis, Tenn.; Benjamin A. Thomas, Philadelphia; Clinton K. Smith, Kansas City, Mo., and Abraham Mattes, New Orleans.

Dr. Herman L. Kretschmer, Chicago, read a paper on "Preoperative Diagnosis of Horseshoe Kidney."

Dr. William E. Stevens, San Francisco, read a paper on "Diagnosis of Renal Tuberculosis."

These two papers were discussed by Drs. W. Calhoun Stirling, Washington, D. C.; Nelse F. Ockerblad, Kansas City, Mo.; Daniel N. Eisendrath, Chicago; Felix Baum, Denver; T. Leon Howard, Denver, and William E. Stevens, San Francisco.

Dr. C. E. Burford, St. Louis, read a paper on "Nephropexy for Relief of Ureteral Kinks Associated with Ptosis."

Dr. Nelse F. Ockerblad, Kansas City, Mo., read a paper on "Stricture of the Ureter in Males."

These two papers were discussed by Drs. Albert E. Goldstein, Baltimore; C. E. Burford, St. Louis, and Nelse F. Ockerblad, Kansas City, Mo.

SECTION ON ORTHOPEDIC SURGERY

Wednesday, April 21—Afternoon

The meeting was called to order at 2:10 by the chairman, Dr. Frank R. Ober, Boston.

The chairman appointed Dr. Arthur Steindler, Iowa City, to serve on the Executive Committee in the absence of Dr. Henry B. Thomas, Chicago.

Dr. W. K. West, Oklahoma City, read a paper on "Fractures of the Shaft of the Femur." Discussed by Drs. H. W. Orr, Lincoln, Neb.; John Dunlop, Los Angeles; H. G. Hill, Memphis, Tenn.; J. P. Lord, Omaha; John Wilson, Los Angeles; C. S. Venable, San Antonio, Texas; N. T. Kirk, Fort Sam Houston, Texas, and W. K. West, Oklahoma City.

Dr. Emil S. Geist, Minneapolis, read a paper on "Removing Splints and Braces from the Patient." Discussed by Drs. Henry W. Meyerding, Rochester, Minn., and F. J. Gaenslen, Milwaukee.

Dr. Ralph Pemberton, Philadelphia, read a paper on "Etiology and Pathology of Arthritis." Discussed by Drs. Frank R. Ober, Boston; Walter G. Stern, Cleveland; C. L. Lowman, Los Angeles; Philip H. Kreuscher, Chicago; Barney Brooks, Nashville, Tenn., and Ralph Pemberton, Philadelphia.

Dr. M F. Arbuckle, St. Louis, read a paper on "Paranasal Cell Infection as a Cause of Infectious Arthritis." Discussed by Dr. W. K. West, Oklahoma City.

Dr. Walter G. Stern, Cleveland, read a paper on "The Value of the Intracutaneous Salt Solution Test in Circulatory Disturbances of the Lower Extremities." Discussed by Dr. Barney Brooks, Nashville, Tenn.; F. J. Gaenslen, Milwaukee, and Walter G. Stern, Cleveland.

Dr. Ralph K. Ghormley, Boston, read a paper on "Heliotherapy with Reference to the Treatment of Tuberculosis of the Spine. Discussed by Drs. Willis C. Campbell, Memphis, Tenn.; W. B. Carrell, Dallas, Texas; Jeremiah Metzger, Tucson, Ariz.; Charles E. Sevier, Colorado Springs, Colo., and Ralph K. Ghormley, Boston.

Dr. C. L. Lowman, Los Angeles, read a paper on "The Rôle of Iliolumbar Ligaments in Low Back Strain Cases." Discussed by Drs. Emil S. Geist, Minneapolis; C. A. Parker, Chicago, and Arthur Steindler, Iowa City.

The following resolution was introduced by Dr. H. W. Orr, Lincoln:

> The Section on Orthopedic Surgery desires to urge that, in its consideration of the matter of medical expert testimony in civil and criminal cases in our courts, due attention be given to the matter of expert testimony in cases involving damages or compensation in industrial and other injury cases.

Dr. Orr moved that the resolution be referred to the House of Delegates for adoption. Motion seconded and carried.

Thursday, April 22—Afternoon

The meeting was called to order at 2:05 by the chairman.

It was moved, seconded and carried that the Executive Committee be given power to appoint one member on a committee of three to arrange for a fracture exhibit next year, also a symposium on fractures.

Dr. Earl D. McBride, Oklahoma City, read a paper on "Dislocation of the Carpal Semilunar Bone." Discussed by Drs. F. J. Gaenslen, Milwaukee; Philip H. Kreuscher, Chicago; James R. Bost, Houston, Texas; Charles F. Clayton, Fort Worth, Texas, and Earl D. McBride, Oklahoma City.

Drs. Frank D. Dickson and Rex L. Diveley, Kansas City, Mo., presented a paper on "A New Operation for the Correction of Moderate Claw Foot." Discussed by Drs. Willis C. Campbell, Memphis, Tenn.; Henry W. Meyerding, Rochester, Minn.; C. L. Lowman, Los Angeles, and Rex L. Diveley, Kansas City, Mo.

Dr. Frank R. Ober, Boston, read the chairman's address, entitled "Diagnosis in Orthopedic Surgery."

Dr. Henry W. Meyerding, Rochester, Minn., read a paper on "The Differential Diagnosis of Bone Tumors." Discussed by Drs. Joseph C. Bloodgood, Baltimore, and E. C. Ernst, St. Louis.

Dr. C. A. Stone, St. Louis, read a paper on "Ossifying Hematoma." Discussed by Drs. Sam Webb, Jr., Dallas, Texas; Walter G. Stern, Cleveland, and C. A. Stone, St. Louis.

Dr. John P. Lord, Omaha, read a paper on "Treatment of Contractures at the Knees." Discussed by Drs. C. A. Parker, Chicago; Earl D. McBride, Oklahoma City, and John P. Lord, Omaha.

Dr. P. A. McIlhenny, New Orleans, read a paper on "Orthopedic Problems of Leprosy." Discussed by Drs. O. E. Denney, Carville, La., and Ralph Hopkins, New Orleans.

Friday, April 23—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Dr. John P. Lord, Omaha; vice chairman, Dr. J. Archer O'Reilly, St. Louis; secretary, Dr. Henry W. Meyerding, Rochester, Minn.; delegate, Dr. H. W. Orr, Lincoln, Neb.; alternate, Dr. H. B. Thomas, Chicago.

Dr. H. W. Orr, Lincoln, Neb., made a brief report on his attendance at the House of Delegates, reporting that the resolution offered Wednesday afternoon was accepted by the reference committee and that it framed its report in such a way as to cover the objects aimed at in the resolution.

A vote of thanks was extended the Texas Orthopedic Club for its hospitality during the meeting.

Dr. J. Albert Key, St. Louis, read a paper on "Some Diagnostic Problems Presented by the Hip in Early Life." Discussed by Drs. Ralph H. Ghormley, Boston; Le Roy C. Abbott, St. Louis; Ben L. Schoolfield, Dallas, Texas; C. B. Francisco, Kansas City, Mo., and J. Albert Key, St. Louis.

Dr. Le Roy C. Abbott, St. Louis, read a paper on "Common Hip Joint Diseases." Discussed by Drs. H. W. Orr, Lincoln, Neb.; E. C. Bull, San Francisco; J. P. Lord, Omaha, and Le Roy C. Abbott, St. Louis.

Dr. J. S. Speed, Memphis, Tenn., read a paper on "Reconstruction of the Hip Joint." Discussed by Drs. Henry W. Meyerding, Rochester, Minn.; Fred H. Albee, New York; Arthur Steindler, Iowa City; Ben L. Schoolfield, Dallas, Texas, and J. S. Speed, Memphis, Tenn.

Dr. Eslie Asbury, Cincinnati, read a paper on "A Study of Spondylolisthesis with Especial Reference to the Cauda Equina." Discussed by Drs. Henry W. Meyerding, Rochester, Minn.; John Dunlop, Los Angeles; J. T. Watkins, San Francisco, and Eslie Asbury, Cincinnati.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

Wednesday, April 21.—Morning

The meeting was called to order at 9 o'clock by the chairman, Dr. Sidney K. Simon, New Orleans.

Dr. Jacob E. Meengs, Grand Rapids, Mich., read a paper on "The Value of the String Test in Cases of Gastric and Duodenal Ulcer." Discussed by Drs. Julius Friedenwald, Baltimore, and Jacob E. Meengs, Grand Rapids, Mich.

Dr. Roger S. Hubbard, Clifton Springs, N. Y., read a paper on "The Alkaline Tide in Achlorhydria." No discussion.

Dr. George B. Eusterman, Rochester, Minn., read a paper on "Gastric Cancer: Present Status of Diagnosis and Prognosis." No discussion.

Dr. Russell S. Boles, Philadelphia, read a paper on "Hodgkin's Disease of the Abdominal Type: Report of a Group of Cases." Discussed by Drs. George P. Muller, Philadelphia; Frank Wright, Chicago; Herbert Hill, San Antonio, Texas; John M. Blackford, Seattle, and Russell S. Boles, Philadelphia.

Dr. J. Rawson Pennington, Chicago, read a paper on "Hemorrhoids." Discussed by Drs. Jerome M. Lynch, New York; Joseph E. Rowan, Wichita, Kan.; Curtice Rosser, Dallas, Texas; Louis Buie, Rochester, Minn.; Andre L. Stapler, Chicago; Alton Ochsner, Madison, Wis., and J. Rawson Pennington, Chicago.

Dr. Curtice Rosser, Dallas, Texas, read a paper on "Clinical Variations in Negro Proctology: The Venereal Factor." Discussed by Drs. J. Rawson Pennington, Chicago; J. F. Montague, New York; Jerome M. Lynch, New York, and Curtice Rosser, Dallas, Texas.

Drs. Julius Friedenwald, Baltimore, and Curtice Rosser, Dallas, Texas, were appointed on the Executive Committee in the absence of Drs. Franklin W. White, Boston, and Ralph W. Jackson, Fall River, Mass.

Thursday, April 22—Morning

The meeting was called to order at 9 o'clock by the chairman.

Dr. Sidney K. Simon, New Orleans, read the chairman's address, entitled "The Teaching of Gastro-Enterology in Our Medical Schools."

Dr. John W. Draper, New York, read a paper on "Congenital Abnormalities of the Omentum in Relation to Gastro-Intestinal Disease." Discussed by Drs. John A. Lichty, Clifton Springs, N. Y., and John W. Draper, New York.

Dr. Edmund Jacobson, Chicago, read a paper on "Spastic Esophagus and Mucous Colitis: Studies in the Etiology and the Treatment by Progressive Relaxation." Discussed by Drs. Russell Boles, Philadelphia; Frank Smithies, Chicago; John W. Draper, New York, and Edmund Jacobson, Chicago.

Dr. Julius Friedenwald, Baltimore, read a paper on "Epigastric Hernia, with Especial Reference to Its Diagnostic Importance in Gastro-Intestinal Affections." Discussed by Drs. John A. Lichty, Clifton Springs, N .Y.; John Phillips, Cleveland, and John J. Gilbride, Philadelphia.

Dr. J. F. Montague, New York, read a paper on "The Clinical Effects of Abnormalities in the Portal Circulation on the Gastro-Intestinal Tract." Discussed by Drs. J. Rawson Pennington, Chicago, and J. F. Montague, New York.

Dr. E. C. Dudley, Chicago, read a paper on "The Treatment of the Psychoneuroses by the Removal of Focal Infections, with Especial Reference to Colectomy and Cecocolectomy." Discussed by Drs. John W. Draper, New York; L. L. Stanley, San Rafael, Calif., and A. H. Coleman, Clinton, N. J.

Dr. W. Howard Barber, New York, read a paper on "Cholecystitis and Its Relation to Pancreatitis." Discussed by Drs. Frank Smithies, Chicago, and John J. Gilbride, Philadelphia.

Dr. John J. Gilbride, Philadelphia, read a paper on "Cholecystography: Its Interpretation and Clinical Application." Discussed by Drs. E. Starr Judd, Rochester, Minn.; George B. Eusterman, Rochester, Minn.; W. H. Olmstead, St. Louis, and John A. Lichty, Clifton Springs, N. Y.

Friday, April 23—Morning

The meeting was called to order at 9 o'clock by the chairman.

The following officers were elected: chairman, Jerome M. Lynch, New York; vice chairman, Joseph Sailer, Philadelphia; secretary, George Eusterman, Rochester, Minn.; delegate, Frank Smithies, Chicago; alternate, Louis A. Buie, Rochester, Minn.

Dr. Kenneth M. Lynch, Dallas, Texas, read a paper on "A Clinical Analysis of Intestinal Flagellate Infection."

Discussed by Drs. Aldo Castellani, New Orleans; John Barrow, Los Angeles; Louis A. Buie, Rochester, Minn.; W. S. Thomas, Clifton Springs, N. Y.; M. D. Levy, Houston, Texas; Frank Smithies, Chicago; Sidney K. Simons, New Orleans, and Kenneth M. Lynch, Dallas, Texas.

Dr. Louis A. Buie, Rochester, Minn., read a paper on "Chronic Ulcerative Colitis." Discussed by Drs. John Blackford, Seattle; E. C. Fishbaugh, Los Angeles; H. G. Walcott, Dallas, Texas; Frank Smithies, Chicago, and Louis A. Buie, Rochester, Minn.

Dr. Sara M. Jordan, Boston read a paper on "Calcium, Carbon Dioxide and Chloride Content of Venous Blood in Cases of Gastric Ulcer Treated with Alkalis." Discussed by Dr. George B Eusterman, Rochester, Minn.; Victor C. Myers, Ph.D., Iowa City; and Drs. John A. Lichty, Clifton Springs, N. Y., and Sara M. Jordan, Boston.

Dr. I. R. Jankelson, Boston, read a paper on "Cardio-Esophageal Relaxation." Discussed by Drs. Frank Smithies, Chicago, and George B. Eusterman, Rochester, Minn.

Dr. E. C. Fishbaugh, Los Angeles, read a paper on "Duodenal Stagnation." Discussed by Drs. Tate Miller, Dallas, Texas; A. J. Potthost, San Antonio, Texas, and E. C. Fishbaugh, Los Angeles.

SECTION ON RADIOLOGY

Wednesday, April 21—Morning

The meeting was called to order at 9 o'clock by the chairman, Dr. A. C. Christie, Washington, D. C.

Dr. Ralph S. Bromer, Philadelphia, read a paper on "Infectious Osteomyelitis: Differential Diagnosis."

Dr. D. Y. Keith, Louisville, Ky., read a paper on "Typhoid Periostitis and Osteitis."

These two papers were discussed by Drs. Albert Soiland, Los Angeles; Henry W. Meyerding, Rochester, Minn.; Edward S. Blaine, Chicago; Ralph S. Bromer, Philadelphia, and D. Y. Keith, Louisville, Ky.

Dr. Amédée Granger, New Orleans, read a paper entitled "New Position for Making Roentgenogram of the Mastoid" Discussed by Drs. Bertram C. Cushway, Chicago; Byron Jackson, Scranton, Pa.; R. H. Lafferty, Charlotte, N. C.; W. F. Manges, Philadelphia; E. H. Skinner, Kansas City, Mo.; William F. Braasch, Rochester, Minn., and Amédée Granger, New Orleans.

Drs. Daniel N. Eisendrath and Irvin S. Koll, Chicago, presented a paper on "Renal and Other Retroperitoneal Tumors: Value of Radiography and Supplementary Methods." Discussed by Drs. Felix Baum, Denver; C. A. Waters, Baltimore; Samuel Brown, Cincinnati; P. M. Hickey, Ann Arbor, Mich., and Daniel N. Eisendrath, Chicago.

Dr. Bundy Allen, Iowa City, read a paper on "The Value of the Pyelogram and Cystogram in Abdominal Diagnosis from the Standpoint of the Roentgenologist." Discussed by Drs. L. R. Sante, St. Louis; Frank Hinman, San Francisco; N. F. Ockerblad, Kansas City, Mo., and Bundy Allen, Iowa City.

Dr. Lloyd Bryan, San Francisco, read a paper on "Gastric Retention of Vegetable Matter." Discussed by Drs. W. W. Watkins, Phoenix, Ariz., and Lloyd Bryan, San Francisco.

Thursday, April 22—Morning

The meeting was called to order at 9 o'clock by the chairman.

Dr. Willis F. Manges, Philadelphia, read a paper on "Pathologic Changes in Lung Tissue as the Result of Foreign Bodies of Long Sojourn." Discussed by Drs. P. M. Hickey, Ann Arbor; L. R. Sante, St. Louis, and Willis F. Manges, Philadelphia.

Dr. L. R. Sante, St. Louis, read a paper on "Pleural Effusions, General and Local: Their Recognition, Localization and Differential Diagnosis." Discussed by Drs. E. S. Blaine, Chicago; Samuel Brown, Cincinnati; Felix Baum, Denver, and L. R. Sante, St. Louis.

Drs. James T. Case and W. O. Upson, Battle Creek, Mich., presented a paper on "Roentgenologic Aspects of Various Types of Hernia." Discussed by Drs. James C. Masson, Rochester, Minn., and James T. Case, Battle Creek, Mich.

Dr. Benjamin H. Orndoff, Chicago, read a paper on "Roentgen-Ray Studies of the Appendix, Cecum and Ascending Colon." Discussed by Drs. H. J. Ullmann, Santa Barbara, Calif ; I. D. Bronfin, Sanatorium, Colo.; E. H. Skinner, Kansas City, Mo., and Benjamin H. Orndoff, Chicago.

Drs. Frank E. Simpson and Roy E. Flesher, Chicago, presented a paper on "Radon (Radium Emanation) as a Palliative Agent in the Treatment of Intra-Oral Cancer." Discussed by Drs. Albert Soiland, Los Angeles; Sanford M. Withers, Denver; J. M. Martin, Dallas, Texas, and Roy E. Flesher, Chicago.

Drs. Montrose T. Burrows and Edwin C. Ernst, St. Louis, presented a paper on "The Relation Between the Effect of the Roentgen Ray and Vitamins on the Organism." Discussed by Drs. Francis Carter Wood, New York; H. J. Ullmann, Santa Barbara, Calif.; L. H. Jorstad, St. Louis, and Edwin C. Ernst, St. Louis.

Friday, April 23—Morning

The meeting was called to order at 9 o'clock by the chairman.

Dr. Curtis F. Burnam, Baltimore, read a paper on "Hodgkin's Disease and Lymphosarcoma, with Especial Reference to Their Theatment by Radiation." Discussed by Drs. Albert Soiland, Los Angeles; Moses Barron, Minneapolis; Samuel Brown, Cincinnati; Benjamin H. Orndoff, Chicago; J. F. Herrick, Ottumwa, Iowa; E. C. Samuel, New Orleans; P. M. Hickey, Ann Arbor, Mich.; Edwin C. Ernst, St. Louis; Ralph E. Myers, Oklahoma City, and Curtis F. Burnam, Baltimore.

Dr. W. S. Lawrence, Memphis, Tenn., read a paper on "Surgical Diathermy as an Aid to Radiotherapy in the Treatment of Malignancy, with Especial Reference to Malignancy Within the Mouth." Discussed by Drs. Grant E. Ward, Baltimore; J. M. Martin, Dallas, Texas, and W. S. Lawrence, Memphis, Tenn.

Dr. Henry Schmitz, Chicago, read a paper on "The Treatment of Inoperable Carcinomas of the Urinary Bladder with Roentgen Rays." Discussed by Drs. C. F. Burnam, Baltimore; W. S. Lawrence, Memphis, Tenn.; Grant E. Ward, Baltimore, and Henry Schmitz, Chicago.

Dr. James A. Corscaden, New York, read a paper on "The Psychoneuroses of the Artificial Menopause." Discussed by Drs. Henry Schmitz, Chicago; R. H. Crockett, San Antonio, Texas, and James A. Corscaden, New York.

Drs. Ethel D. Humphrys, Sanford M. Withers and John R. Ranson, Denver, presented a paper on "Shortening the Quarantine Period for Diphtheria Convalescents and Carriers." Discussed by Drs. P. M. Hickey, Ann Arbor, Mich., and Sanford M. Withers, Denver.

Drs. E. C. Samuel and H. N. Blum, New Orleans, presented a paper on "Roentgen-Ray Therapy of Exudative Iritis." Discussed by Drs. Byron Jackson, Scranton, Pa.; M. W. Kapp, San Jose, Calif., and E. C. Samuel, New Orleans.

The following officers were elected: chairman, Dr. Albert Soiland, Los Angeles; vice chairman, Dr. E. C. Samuel, New Orleans; secretary, Dr. Frederick M. Hodges, Richmond, Va.; delegate, Dr. James T. Case, Battle Creek, Mich.; alternate, Dr. E. H. Skinner, Kansas City, Mo.

Primitive Medicine and Scientific Medicine.—The magical and religious categories of primitive medicine frequently crop up throughout later history, dominating the picture in the middle ages, and occurring sporadically even in modern times; for example, in Heinroth's doctrine that mental disorder is due to sin and in the present-day conceptions of Christian science. But they lie altogether outside the path of development of scientific medicine, and our only interest here is in the gradual evolution of the category of natural causes.—Hart, Bernard: *Lancet* **1:**587 (March 20) 1926.

SATURDAY, MAY 8, 1926

THE THERAPEUTIC USE OF OXYGEN

The use of gaseous oxygen for therapeutic purposes, while not a novelty, has fallen into apparent disrepute and consequent disuse. The oxygen cylinder of two decades ago is no longer seen at the bedside of those who are desperately ill. This outcome is due in part to a changed view with respect to the functions of oxygen. The theory of "suboxidation" in the body has undergone some radical revisions. Yet there can be little doubt that anoxemia is an actual possibility in human practice. It may occur after hemorrhage and in anemia; it may follow the restriction of a free influx of air into the lungs; and it is a demonstrable symptom in many cases of lobar pneumonia. Under such circumstances the menace of inadequate "arterialization" of the blood occurs with a consequent burden on the cardiorespiratory and central nervous systems. There is accordingly a rational basis for administration of oxygen;[1] but it does not consist in the exhibition of a few whiffs of the gas through a funnel held in front of a patient's face. Ordinarily, the inspired air contains approximately 21 per cent of oxygen. It requires a decided increment of the latter in the air intake to produce effective gains by diffusion through the lungs into the pulmonary capillaries. To be of therapeutic potency, oxygen should be administered at an optimal concentration, which has lately been proposed at about 40 per cent of the inspired air. This was impossible of attainment in the older procedures.

Improvement came with the development of special apparatus to insure inspiration of higher concentrations of oxygen when it was desired. Barach[2] has recently reviewed the history of these efforts. The effective administration of oxygen apparently began in 1917, when the Haldane apparatus was used in the treatment of acute pulmonary edema of war gas poisoning. During the same year, Meltzer reported the successful use of the oral insufflation apparatus. In 1921, Barach and Woodwell described a rebreathing apparatus for cases of pneumonia and cardiac insufficiency. Henderson, in 1922, described an apparatus employed in resuscitation from gas poisoning, and suggested its use in pneumonia. Since 1921, oxygen chambers have been used by Barcroft and Poulton in England and by Stadie and Binger in this country. A bed tent was described by Hill, a head tent by Roth, and recently a portable oxygen tent by Barach and Binger. The nasal catheter was introduced during the war and has been widely used since then. In recent tests of some of the procedures of administering oxygen at the Presbyterian Hospital, New York, Barach[2] ascertained the oxygen concentration of the nasopharyngeal air, and calculated the oxygen concentration of the inspired air, and the arterial oxygen saturation before and after treatment. The tube and funnel method at its maximum efficiency raises the air in the nasopharynx to 22 per cent, and may be considered almost useless as a therapeutic agent. With oxygen administered at 2 liters per minute, the inspired air has an oxygen concentration of approximately 24 per cent. The nasal catheter may vary in its effectiveness to the extent that the nasopharyngeal air may contain between 22 and 35 per cent of oxygen, depending largely on the rate of administration of oxygen from the tank. When catheter oxygen treatment is carried out at its maximum efficiency, there is apt to be considerable increase in the oxygen saturation of the arterial blood, particularly in the mild and moderate cases of oxygen want. For the relief of severe arterial anoxemia, higher concentrations of oxygen than this method affords appear to be necessary. According to Barach, rebreathing apparatus with the use of a specially constructed glass nosepiece is the most efficient of the easily portable types of apparatus and in most cases causes little discomfort to the patient. Observations on the arterial blood confirm the effectiveness of the method. The portable oxygen tent as devised by Binger and Barach was used in the majority of cases treated. It secured an oxygen-rich atmosphere susceptible of regulation at the precise concentration desired. It accomplished adequate removal of carbon dioxide, moisture and heat, and was comfortable for the patient to live in, except in warm weather.

In an earlier issue of The Journal,[3] the favorable outlook, under the improved technic, for a usefulness of oxygen therapy in pneumonia was mentioned. The latest report[2] supports the former impressions. Treatment in the oxygen tent appears promising. Gravely ill patients are likely to show clinical signs of improvement after inhalation of from 40 to 60 per cent of oxygen in the air. They appear more comfortable, with the disappearance or diminution of cyanosis, decrease of restlessness, and at times relief of dyspnea. In many instances there is a drop in the pulse or the respiratory rate or in both; and there is a tendency to lessened delirium. There are demonstrable reasons for these consequences. The arterial oxygen saturation was increased in all the tested cases. In severe arterial anoxemia, the inhalation of from 40 to 60 per cent of oxygen raised the arterial oxygen saturation substantially, but not to the normal level. The arterial carbon dioxide content was lowered in some persons. This decrease was severe in only one patient.

[3] Oxygen Therapy in Pneumonia, editorial, J. A. M. A. **85**: 37 (July 4) 1925.

It should not be supposed, of course, that administration of oxygen will combat the micro-organisms directly. The grave prognosis of persistent bacteremia in lobar pneumonia is unaltered by the administration of oxygen. Barach frankly insists that the value of this treatment is supportive and not curative. In his observations of severe dyspnea with cyanosis, oxygen treatment has appeared to prolong life until such a time as the immunity mechanism was able to accomplish recovery. That alone represents no mean benefit.

THE RETENTION OF URIC ACID

Somehow, uric acid does not lose its popularity as a subject of discussion. Scarcely a year passes that does not bring significant new facts relating to the chemical physiology of this substance. With them goes the formulation of new hypotheses and the rejection of others. The physician and, to a large degree, the layman have, however, become extremely cautious when reading facile publications about uric acid. What Barker [1] wrote twenty years ago as an introduction to his "Truth and Poetry Concerning Uric Acid" is equally applicable today:

> In the slow but steady advance which medicine is making, new facts are often established for a long time before they meet with general acceptance, and old theories have had their foundations washed out from under them years or decades before their fallacies have become generally recognized by the profession. It is easy to be too severe in criticizing the inertia of medical men in this respect, for the very conservatism which accounts for the facts mentioned has gone far to protect our guild from the too speedy welcoming of immature conceptions, on the one hand, and from the too easy rejection, on the other, of theories which, under assault by partisan or ignorant critics, prove ultimately to be sound. It is not an unwillingness to accept new truth or a desire stubbornly to retain error which is characteristic of our profession. On the contrary, it is rather the fear of being duped concerning the new or of being cheated of old and well tried good which animates it and determines its action or inaction.

The determination of the level of circulating uric acid in the blood is today comparatively an easy task. The progress of biochemical analysis has firmly established the fact that the blood content often is increased above what experience has shown to be a fairly constant normal in healthy persons. For a long time the power of the human organism to destroy uric acid has been seriously questioned, so that the quantitative variability in its concentration in the blood was not likely to be associated with changes in the metabolic disintegration of this purine compound. Of late, however, there has been a revival of the view that uric acid is subject to both destruction and elimination by the organism, as well as production in it.[2]

The accumulation of uric acid in the blood has also been looked on as evidence of renal impairment; but it must be admitted that such retention has been demonstrated to occur without coincident retention of nonprotein or urea nitrogen in persons whose kidneys were normal by the usual tests.[3] This finding throws doubt on the value of increased uric acid in the blood as an indication of renal impairment. It has long been known that the excretion of uric acid is greatly decreased in the absence of food;[4] and Lennox [5] has demonstrated that the decreased uric acid output during fasting is due to retention of the substance within the body. From his latest studies he concludes that kidneys and general body tissues both play a part in fasting retention; and it seems probable that the same is true for gout, in which similar conditions in blood and urine prevail.

Lennox believes that of the series of physiologic and chemical changes in body structure and function that occur during fasting, disturbance in the three following might be concerned in uric acid retention: (1) equilibrium of electrolytes (with resulting changes in water balance); (2) acid-base relationships of body tissues, including kidney or blood; (3) oxidation of fat with associated utilization of glucose. Because variations in acid-base relationships are more easily measured, they may have received undue prominence in this study. Disturbances in oxidation may be more fundamental. Some writers have explained the high blood uric acid found in cases of severe anoxemia, as in carbon monoxide poisoning, on the basis of diminished destruction (oxidation) of uric acid. Though that theory is discredited, it is possible that decreased or incomplete oxidation of body material results not in decreased oxidation of uric acid but in its retention. All the three possible factors that have been mentioned, Lennox adds, are interrelated. Their proper correlation, and the exact mechanism involved in retention of uric acid, must await other investigators and further knowledge. The complete explanation, when it comes, will probably not be simple. The problem of uric acid retention in fasting is probably, in its essentials, the old, unsolved problem of gout.

In a practical way it is significant that food, or at least the metabolism associated with its intake, facilitates the output of uric acid. It has long been known that ingestion of certain substances, not purine in nature and therefore presumably not immediate precursors of uric acid, increases the urinary output of the latter. Proteins and carbohydrates are more potent in this respect than fats; at any rate, feeding of the latter did not relieve uric acid retention. In relation to gout, Lennox's observations on the effects of foods have led him to suggest that overeating of fat, rather than of protein, is of etiologic importance. In relation to treatment, they suggest the use of a low fat diet—one consisting mainly of carbohydrate and protein. If this seems too heterodox, we may recall Barker's reminder that no one who grows can escape the pain of being forced, now and then, to sacrifice dearly cherished opinions; but if truth is followed, a satisfaction is always gained superior to that which has been lost.

A STUDY OF GASTRIC MOTILITY

All contractile tissues that exhibit an inherent rhythmicity in their performance present the problem of where and how the muscular movements are initiated and what physiologic device facilitates the orderly sequence of contractile changes. This well regulated progression of performance is exemplified in the action of the heart, in which the beat of one part is followed under precisely defined conditions by the contraction of another chamber. Even slight disturbance of this rhythmic program is indicative of a pathologic condition. Modern study has directed attention to the so-called pacemaker of the heart. The cardiac organs of the lower forms exhibit a series of different chambers, beginning with the sinus venosus, into which the great veins open and from which the excitation wave spreads. In the human and other mammalian hearts, a remnant of the sinus venosus is found in the right auricle at the junction of the superior vena cava. It is represented by the collection of tissue known as the sino-auricular or Keith-Flack node. The beat of the heart begins in this tissue and spreads directly to the auricular muscle. The auriculoventricular bundle of His provides a path of conduction of impulses from auricle to ventricle. Interference with its function has been made familiar through the manifestations of the Adams-Stokes syndrome.

There are evident analogies between the features of cardiac physiology and those of alimentary peristalsis. The latter involves the orderly successive contractions of muscular structures, some of which are arranged into organs. Gastric motility is concerned with them. Various attempts have been made in recent years to find, in the stomach activities, phenomena parallel to those observed in the heart. This has involved the effort, for example, to discover the presence of a nodal center in which the gastric waves arise and a conduction system through which they are propagated.

In his studies at the Department of Surgery in the Columbia University College of Physicians and Surgeons, Klein[1] believes that he has found a gastric pacemaker that corresponds in some degree to the sino-auricular node of the heart. There is both anatomic and experimental evidence for the belief that the gastric wave originates in a nodal center on the lesser curvature at the cardia. The impulse passes down along the lesser curvature. As it reaches each point on the lesser curvature, the entire circular ring at that level contracts and so the peristaltic wave passes down. At the reentrant angle there is a nodal center for the muscular activity of the antrum. Klein reminds us that excisions of portions of the lesser curvature by the surgeon and destruction of areas by such pathologic processes as ulcer give further evidence as to the importance of this part of the stomach for normal motility. An ulcer on the lesser curvature is notoriously associated with delayed gastric motility and with vomiting. In contradistinction to this, large lesions of the body and greater curvature of the stomach are attended with far less disturbance of motility. Many clinical phenomena are more readily interpreted on Klein's hypothesis that irritating lesions on the lesser curvature may cause a persistent contraction of the circular muscle at the level of irritation, whereas excision or destruction of a portion of the lesser curvature disturbs the orderly conduction, so that weakened peristalsis results beyond that level.

Current Comment

THE QUARTERLY REVIEW OF BIOLOGY

The study of living tissues and the phenomena that concern them is fundamental to the study of medicine. Thus it is that the practice of the latter science involves a knowledge—at least an elementary knowledge—of all other sciences. So great is the mass of information available today that all agree it is beyond the memory and the comprehension of any one man. Nevertheless, the fundamental principles governing life should be familiar to every medical man. Indeed, the view is generally accepted that our civilization can advance only to the extent that general knowledge of these matters becomes available to all men. In the foreword to a new periodical, the *Quarterly Review of Biology*,[1] Prof. Raymond Pearl, its editor, says, "Popular scientific writing which takes as its target the mental age of about ten is, we believe, quite as nauseating to intelligent lay readers as it is to men of science." But he believes there is a fairly numerous body of cultivated men and women who are genuinely interested in knowing about the progress of biology, and quite as capable of understanding clearly written essays in this field as may be the average scientist. This new periodical is offered, therefore, to the group which in the literary field is somewhat sneeringly known as the "intelligentsia." It is offered as well to readers in all the sciences who are interested in correlating actual accomplishments of research in one field with the advancement in others. Only by education will follies and fallacies be overcome. Professor Pearl challenges ignorance with the defiance of science. "The plain fact, of course, is," he says, "that there can never be any real compromise between science and mysticism, between the real and the supernatural, between light and darkness, between the demonstrable verifiable truth which makes us free and ancient superstitions grounded in phallic folklore. . . . Man's emancipation from the domination of priesthoods of one breed or another has been in precise proportion to the depth and breadth of the understanding of nature which science has given him."

THE INCUBUS OF THE HARRISON NARCOTIC ACT

Under cloak of the Harrison Narcotic Act physicians were saddled for years with a quarter million dollar tax annually in excess of the tax necessary to make the act valid. They have just convinced Congress of the injustice of that burden, and it will be removed, July 1. Now, however, comes a threat of other burdens even more serious. For the purpose of "strengthening" the Harrison Narcotic Act, a bill has been introduced into Congress limiting the right of physicians to use narcotics, imposing additional duties on them with respect to such narcotics as they may lawfully use, and greatly increasing the penalty for violations of the act, intentional or unintentional. The bill is discussed elsewhere in this issue.[1] This legislation is in effect a confession by the officers charged with the execution of the Harrison Narcotic Act that in its present form it cannot accomplish the purpose for which it was passed. In effect, it charges the responsibility for failure to deficiencies in the act itself, instead of to the inadequacy or inefficiency of enforcement officers. A study of the proposed bill certainly raises some doubts as to its adequacy to accomplish more than has been achieved by previous legislation. The hearings on the bill will be awaited with interest.

AGAIN, PROTEST THE SHEPPARD-TOWNER ACT

The Journal, February 6, called attention to bills pending in Congress to authorize operations under the Sheppard-Towner Act for two years beyond the limit originally fixed for the termination of such activities. The House of Delegates had previously condemned the original act. The Journal, therefore, appealed to constituent societies and other agencies to support the action of the House by protesting to their senators and representatives against the enactment of these bills to extend its life. Such a bill has, however, passed the House of Representatives. In the Senate, the Committee on Education and Labor reported favorably the bill already enacted by the House, but recommended that authority for prolonging operations under the act be limited to one year. This abbreviation of the proposed prolongation of the life of the act was based on the opinion of the committee that the functions taken over by the federal government under the Sheppard-Towner Act were state functions and should be allowed to revert to the states. The evidence offered by the proponents of the pending legislation to justify its enactment, so far as such evidence is available, is of a most general and uncertain character, and much of it comes from interested witnesses. Certainly it is not such as to convince any person accustomed to weigh evidence concerning such matters that the Sheppard-Towner act has reduced or ever will reduce maternal or infant mortality beyond the reduction that the states themselves might effect. Nor is the evidence such as will convince a careful student of government that the federal government can continue to buy from the states, through subsidies, the right to supervise and control state activities that the federal government under the constitution cannot directly control, without endangering our entire system of government. The proponents of the pending bills frankly admit that the two years' extension they have sought is not sufficient to accomplish the purpose of the act, and that additional extensions for indefinite periods will be required. They are not likely, therefore, to omit any effort to have the Senate reject the recommendation of the committee that the life of the act be prolonged for one year only and enact the bill as passed by the House, providing two years' extension. Those who believe that the Sheppard-Towner act is essentially pernicious will do well, therefore, to continue their efforts to defeat any legislation looking toward the extension of the act for any period whatever. Action toward that end may accomplish its purpose, and even if it does not, it will tend to support the recommendation of the committee for a one year extension only. Protests, to be effective, should be sent immediately, by telegram or special delivery, as the bill may come up for action at any time.

PHYSICIANS IN PUBLIC LIFE

In a recent issue,[1] reference was made to physicians serving in the American congress. The record for medical representation in parliament seems, however, to belong, by far, to a South American country. A Uruguayan contemporary[2] states that in the last elections five physicians were appointed to the senate and twenty-five to the house of representatives. Uruguay is a rather small but a wealthy and progressive country, with a population of about 1,500,000 and less than 1,000 physicians. As there are about nineteen senators and 125 representatives, physicians make a little less than one fourth of the senate membership and one fifth of the house. This cannot be attributed to undue fondness of politics on the part of our Uruguayan confrères, as a number of those elected to congress have already expressed their intention of refusing the honor. Physicians have always been prominent in public life throughout Latin America. Unanue, the Peruvian statesman whose statue stands now in Washington, is undoubtedly the best example. Recent deaths have served to recall the rôle assumed by such men as Damianowich and Sandoval in the early Argentine wars, and de Toledo Piza in changing Brazil from an empire into a republic. At present, physicians are filling not only such positions as might naturally seem of their incumbency, as secretaries of public health—Cuba, Chile, Colombia, Salvador—and university presidents—Mexico, Buenos Aires, Santiago de Chile, Guayaquil—but others less connected with medicine, in the highest diplomatic and consular ranks, including secretary of state in Venezuela, secretary of education in Mexico, and vice president of the republic in Nicaragua.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

State Medical Election.—At the annual meeting of the Medical Association of the State of Alabama, April 27-30, Dr. Aaron L. Harlan, Alexander City, was elected president; Drs. George A. Cryer, Anniston, Thomas Joseph Dean, Union Springs, Victor H. Williams, Jasper, and Kossuth A. Mayer, Lower Peach Tree, vice presidents; Dr. Douglas L. Cannon, Montgomery, assistant secretary, and Dr. Jacob U. Ray, Jr., Woodstock, treasurer.

CALIFORNIA

Vaccination in Los Angeles.—More than 300,000 persons were vaccinated against smallpox by the Los Angeles City Department of Health between January 1 and March 6; of this number at least 120,000 were pupils in the public schools; 65,000 employees in industry, and 5,000 inmates of institutions.

Society News.—Dr. Victor G. Vecki, San Francisco, addressed the Los Angeles County Medical Association, April 15, on "Organization of the Medical Profession in the United States," and Dr. Anders Peterson on "Perinephritic Abscess Following Peripheral Infections."——Among others, Dr. Ray Lyman Wilbur, president of Stanford University addressed the fourth annual meeting of the Pacific Coast Oto-Ophthalmological Society, San Francisco, April 26-28, on "Medical Education in Relation to the Specialists."

"Evreco Oil" Rubs.—T. C. Everhart, Venice, pleaded guilty, February 11, to violation of the medical practice act, and was sentenced to 100 days in jail, the sentence being suspended for two years on condition of good behavior. Although Everhart, the state board of medical examiners says, has no medical education whatever, he has been treating patients at Venice during the last two years with "Evreco Oil," which he rubs on for rheumatism and paralysis, seven rubs, with some other medicine, costing from $100 to $500. Everhart, when arrested, was treating a wealthy Canadian who came to California in a special car.

Smallpox Kills One Hundred and Sixty-Three in Three Months.—The report of the California State Board of Health for the first quarter this year shows that 163 persons are known to have died of smallpox; there were 1,836 cases reported. The fatality rate for the entire state for this period was 8.8 per cent, but it was 17 per cent in some localities; 136 of the deaths occurred in the city of Los Angeles and six others in Los Angeles County; six occurred in San Francisco County. During the first ten days of April, thirty-five deaths were reported to the state board. There are indications, it is said, that the children in communities in which the disease is most prevalent are now "rather extensively" immunized. The disease, however, continues to take a heavy toll among unvaccinated adults.

Summer Institute for Nurses.—The fifth annual institute for public health nurses will be held at Berkeley, July 12-23, sponsored by the University of California and the state board of health. The institute is designed to provide a means for the exchange of practical ideas to make school and community nursing more efficient, and to provide a review of technical subjects concerning the control of communicable disease. Any public health nurse with at least one year of experience is eligible to admission, and certificates of attendance will be given those who register and attend all sessions. Meetings will be held in the afternoons except Saturday, and mornings will be used in visiting health centers in the nearby communities. Inquiries should be addressed to the California State Board of Health, Sacramento.

FLORIDA

Medical Arts Building.—The Medical Arts Building Company, Tampa, announces that it will erect a twelve story office building at the corner of Plant and Grand Central avenues, at a cost of about $1,200,000, which will be devoted exclusively to the use of physicians and dentists. The project, which is said to have been approved by the Hillsborough County Medical Society, has been financed and the site purchased, and nearly all the space in the building leased. The structure has been planned to provide the utmost convenience to the two professions.

State Board of Health Items.—There had been 1,279 cases of smallpox in Florida in the recent outbreak up to March 13 with only two deaths; medical officers vaccinated 14,000 people in February. The town of Callahan, according to the state board of health, is practically 100 per cent vaccinated against smallpox; most of the cities of the state have been reporting all cases to the state board; a few cities, it is said, have reported only a fraction of their known cases; for example, a city is cited that reported less than six cases to the bureau of vital statistics, while the city physician personally knew of more than forty cases in that community.

GEORGIA

State Medical Meeting.—The seventy-seventh annual meeting of the Medical Association of Georgia will be at Albany, May 12-15, under the presidency of Dr. Frank K. Boland, Atlanta. Meetings will be held at the City Auditorium, and the Wednesday morning session will be open to the public also the Thursday noon session, when the president delivers his address. The annual banquet will be Thursday evening at 7 o'clock. The house of delegates meets Tuesday at 7:30 p. m., and Wednesday and Thursday at 8 a. m. The council meets at 5 p. m. Tuesday, and the conference of secretaries Thursday, 5:30 p. m. Dr. Seale Harris, Birmingham, Ala., past president of the Southern Medical Association, will be the guest of the association; Dr. Harris will give an address on "Low Carbohydrate Relatively High Fat and Rich Vitamin Diet in the Treatment of Gastric and Duodenal Ulcer." The scientific program includes many of the prominent physicians of the state. The Georgia Pediatric Society will hold a smoker, Wednesday evening.

ILLINOIS

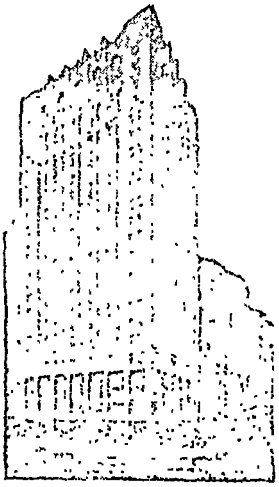
Home for Blind Babies.—The International Sunshine Society, Inc., a newspaper club, desires to locate the blind babies and young blind children of Illinois in order to help secure a law that will provide care for blind babies; there is only one institution in the country, it is said, the Arthur Home-Hospital and Kindergarten for the Blind at Summit, N. J., which, for a small daily allowance, will take blind babies of any race or creed and give them special care and instruction. Persons who know of blind babies are requested to communicate with Mrs. John Alden, 96 Fifth Avenue, New York, president of the International Sunshine Department for Blind Babies.

Society News.—Dr. Elven J. Berkheiser, Chicago, addressed the Will and Grundy County Medical Society, Joliet, April 14, on "Diagnosis of Vertebral Lesions."——Dr. Edwin J. Gardiner has been elected president of the Chicago Ophthalmological Society; Dr. Dwight C. Orcutt, vice president, and Dr. Robert H. Buck, secretary-treasurer.——Dr. Lewis J. Pollock, associate professor of neurology, Northwestern University College of Medicine, Chicago, gave an illustrated address before the Mercer County Medical Society, April 12, on the "New Logic of Diagnosis."——Dr. Stuart Pritchard, Battle Creek, Mich., gave a demonstration of the use of lipiodol in roentgen-ray work before the Decatur Medical Society at the Decatur and Macon County Hospital, April 15.

Chicago

Society News.—Dr. Stuart Pritchard, Battle Creek, Mich., will address the annual meeting of the Chicago Tuberculosis Society at the Brevoort Hotel, May 13, 8 o'clock, on "Value of Iodized Oil in Bronchial Infections from a Diagnostic and Therapeutic Standpoint."——There will be a symposium on bone tumors at the annual meeting of the Chicago Roentgen Society, Virginia Hotel, May 13, by Drs. William C. MacCarty and Henry W. Meyerding, both of Rochester, Minn., and Anatole Kolodny, Iowa City. ——The final meeting of the season of the Chicago Ophthalmological Society will be at the Hotel Sherman, May 17; Dr. William H. Luedde, St. Louis University School of Medicine, St. Louis, will give an address on "The Mechanism of Accommodation," and Dr. Robert Von der Heydt will demonstrate the Nordenson-Zeiss camera for photographing the fundus.——The monthly clinical meeting of the Chicago Surgical Society was held at the Research and Educational Hospital, University of Illinois, May 7.——Dr. Arthur E. Guedel, Indianapolis, addressed the Chicago Medical Society, May 5, on "Metabolism and the Anesthetic."——Attention of members of the Chicago Medical Society has been directed to the three hundred and sixty-fifth medical squadron, organized reserves, which is being organized; the following vacancies exist: three captains and four lieutenants in the medical section; one lieutenant in the dental section; one captain in the veterinary section. Information may be obtained from Lieut.-Col. John G. Winter, Executive Officer, headquarters, Sixty-Fifth Cavalry Division, Telephone, State 5365.

Medical Arts Building.—The Medical and Dental Arts Club of Chicago announces that it will erect a twenty-three story professional building at the southeast corner of Wabash Avenue and Lake Street which will be ready for occupancy, May 1, 1927. Plans for the building have been made by D. H. Burnham and Company, architects, and the finances arranged by a $3,100,000 loan from S. W. Strauss and Company. The objects of the Medical and Dental Arts Club are to provide a permanent home for all the medical and dental societies in Chicago; to establish a social professional club for its members, and to create a commercial center for the leading medical and dental supply houses. The top floors of the building will contain clubrooms, reading rooms, dining rooms and lounge; the twenty-first to fourteenth floors, offices for physicians and dentists; the fourteenth to the seventh floors will be for medical and dental supply houses; the fifth and sixth floors will be an auditorium and headquarters for the Chicago Medical Society and the local and national dental associations, and the first four floors will contain stores. Membership in the Medical and Dental Arts Club is restricted to members of the Chicago Medical Society and the Chicago Dental Society. This project is the first in any city to create a professional center for the commercial, social and scientific activities of the two professions. There are nearly fifty special medical and dental societies in Chicago which will be enabled to have quarters in this building. The board of trustees of the Medical and Dental Arts Club include Drs. Frank Billings, William Allen Pusey, Jeremiah H. Walsh, Hugh N. MacKechnie, Charles E. Humiston, and, in the dental profession, Drs. Otto U. King, Charles N. Johnson, Alexander A. Goldsmith and M. M. Printz. Dr. John S. Nagel is the president of the club; Drs. John H. Cadmus and Robert H. Hayes, vice presidents; Dr. Frederick R. Green, secretary; Dr. Harry B. Pinney, treasurer, and Mr. John A. King, business manager.



IOWA

Society News.—Members of the Scott and Rock Island County Medical Societies in joint session, April 6, voted to close their offices Wednesday afternoons during the summer months, and to hold a "big outdoor picnic," probably in June. ——Dr. Arthur Steindler, professor of orthopedics, State University of Iowa College of Medicine, Iowa City, gave an illustrated lecture before the Scott-Rock Island County Medical Societies, Davenport, April 6, on "Compression Paraplegia in Spinal Diseases."

Personal.—Dr. Glen W. Doolen, Davenport, has been reappointed as Scott County physician.——Dr. Elmer L. Lampe has been appointed health officer of Bellevue to succeed Dr. John C. Dennison, resigned, who held that position for many years.——Dr. H. G. Clarke, Perry Point, Md., has arrived in Knoxville as the new officer in charge of the local U. S. Veterans' Bureau Hospital, and Dr. Otto R. Lynch, Los Angeles, has arrived and will be the assistant to the superintendent of the hospital.

Iowa Heart Association.—The second annual meeting of this association will be held, May 14, at the Fort Des Moines Hotel, Des Moines. Dr. Paul D. White, Massachusetts General Hospital, Boston, will speak on "The Conservation of Hearts"; Dr. Fred M. Smith, State University of Iowa College of Medicine, Iowa City, "The Future of Heart Work in Iowa." There will be a report on the year's work, and a business meeting following the luncheon, with election of officers. All members of the association and all other physicians interested are cordially invited to attend.

MICHIGAN

Degrees in Public Health.—The dean of the Detroit College of Medicine and Surgery writes that degrees of Doctor of Public Health (Dr.P.H.) are never issued to any one who does not already hold a degree of Doctor of Medicine from a reputable medical school. This is in reply to an item in The Journal, March 27, based on a resolution adopted by the Ingham County Medical Society.

Society News.—Dr. David Clark, clinical professor of psychiatry, Detroit College of Medicine, Detroit, addressed the Washtenaw County Medical Society, Ann Arbor, April 29, on "Trouble Cases from the Mental Angle"; Dr. Clark's paper was discussed by Dr. Hugh Cabot, dean of the University of Michigan Medical School, Ann Arbor, and by Dr. James D. Bruce, chief of the medical service.

MISSOURI

Personal.—Dr. Cecil L. Wayman has been appointed tuberculosis controller of St. Louis by the hospital commissioner. ——Dr. Homer F. White has been appointed superintendent of the General Hospital, Kansas City, to succeed Dr. T. A. Kyner.——Dr. David P. Ferris, St. Louis, has been appointed chief otolaryngologist at Alexian Brothers' Hospital and director of the department at Alexian Brothers' Dispensary.——In a reorganization of the health department of Kansas City, by the director of health, Dr. Ernest W. Cavaness, Dr. Leonard Mason Lyons was appointed city epidemiologist, and Dr. John L. Lavan, commissioner of child hygiene and communicable diseases.

U. S. Supreme Court Upholds State Board.—An opinion was recently handed down in the Supreme Court of the United States by Justice Stone, upholding the Missouri State Board of Health in revoking the license to practice medicine of Dr. Leon Hurwitz, who was charged by the board with having performed an illegal operation. When the Supreme Court of Missouri decided in favor of the state board, Dr. Hurwitz took the case to the U. S. Supreme Court, claiming that the board had exceeded its authority and that its action was in violation of the constitution. The Supreme Court of the United States decided, April 12, that the state board of health had the right to proceed with this investigation and on conviction to revoke Dr. Hurwitz' license to practice medicine. This is said to be the first case of this character to be decided by the U. S. Supreme Court. The Missouri State Board of Health was represented by Attorney General North T. Gentry of Jefferson City.

NEW YORK

Raise of Pay for Health Officers.—The governor signed a bill, April 12, which will increase the salary of health officers of the state in villages and cities of more than 8,000 population from a minimum of $800 to $1,200; in towns and villages of less than 8,000 population, the rate per capita for health officers is increased from 10 cents to 15 cents. The new law also allows health officers extra compensation for taking cultures, and provides for the appointment of a substitute when the health officer is absent.

Legislature to Investigate Chiropractic.—A resolution has been adopted by both houses of the New York legislature which provides for an investigation into the practice of chiropractic in the state by a joint committee comprising two senators and three members of the assembly. The committee will inquire into the nature and work of chiropractors in the state, their qualifications, and will propose such legislation as it deems necessary to regulate and control the practice of chiropractic. The committee is empowered to employ counsel and other assistants and to incur expenses of not more than $5,000. A report will be submitted to the legislature on or before Feb. 15, 1927.

Annual Tuberculosis Meeting.—The state committee on tuberculosis and public health of the State Charities Aid Association will hold its annual meeting, June 1-3, in Cattaraugus County, with headquarters at Olean and Salamanca, in order to facilitate a study of the health demonstration which has been going on in that county with the financial assistance of the Milbank Memorial Fund for about four years. The program is planned to give every opportunity to observe how this demonstration is being done. There will be visits to Allegany State Park, where the children's camp is, and to the county tuberculosis sanatorium at Rocky Crest. Delegates will be conducted to all parts of the county; Sir Arthur Newsholme, formerly principal medical officer of the local government board of England, will give an address the first day.

New York City

Dr. Stewart Appointed Medical Director.—It was announced, April 29, that Dr. George David Stewart had been appointed medical director of the Broad Street Hospital and Dr. Arthur M. Wright, assistant medical director; plans have been made, it is said, for a complete reorganization of the hospital.

Library News.—The library of the New York Academy of Medicine has just procured from Germany a copy of another incunabulum "De Proprietatibus Rerum" by Bartholomaeus Anglicus, printed in 1483. The work consists of nineteen books, of which numbers 5, 6 and 7 are anatomic and medical.——The library of the late Dr. Nathan E. Brill has been presented to the Academy of Medicine by the widow.

Distribution of Hospital Fund.—The distributing committee of the United Hospital Fund met in the mayor's office at the city hall, April 15, and distributed nearly $600,000 among the fifty-six member hospitals of the fund, as the public's contribution this year toward meeting the cost of hospital care for the poor. The funds are distributed in proportion to the amount of free service given to the poor, regardless of race or creed.

Personal.—Dr. William H. Godsick has been appointed assistant attending gynecologist and obstetrician to the Lincoln Hospital.——Dr. Louis Kleinfeld, chief, ear, nose and throat-clinic, Mount Sinai Hospital, has been appointed adjunct laryngologist to the hospital; Dr. Kleinfeld has resigned from the otolaryngologic staff at the Manhattan State Hospital.——Sir Spencer Lister, research bacteriologist for the South African Institute of Medical Research, Johannesburg, arrived in New York, April 17.——Dr. Jacob Sobel has been appointed attending pediatrician to the Hospital for Joint Diseases.

NORTH CAROLINA

Wing of State Hospital Burned.—A wing of the state hospital for the insane, at Raleigh, was destroyed by fire, April 10, at a loss estimated at $500,000. The patients were all moved without injury to any one. The wing destroyed was built in 1853.

Hospital News.—The North Carolina State Institution for the Blind has let the contract for the new hospital for which the last legislature authorized an appropriation of $50,000. ——Dr. S. Dace McPherson, Durham, announces the opening of a private hospital, the McPherson Hospital, for the treatment of diseases of the eye, ear, nose and throat.

Summer Postgraduate Instruction.—North Carolina physicians will have the opportunity this summer of attending lectures and clinics conducted by specialists under the auspices of the university extension division in each of six different cities for two hours once a week for twelve weeks. The courses have been offered to ten cities, and the six that first procure the fifteen signatures of physicians required will receive the courses. The instructors will be Dr. Howard B. Sprague, Boston, diseases of the heart; Dr. Edward S. Emery, Jr., Boston, diseases of the gastro-intestinal tract, and Dr. Dwight O'Hara, Waltham, Mass., diseases incident to middle and old age.

OREGON

Hospital News.—The $270,000 addition to the Emanuel Hospital, Portland, which was dedicated in March, has five stories, sixty-three private rooms and twenty-six rooms for two or more patients; the Swedish Lutheran Church manages the hospital.——The Pacific Protective Society of Portland is raising $60,000 to complete the Juvenile Hospital for Girls, which is located near Troutdale.

Society News.—A two day clinic was conducted before the Klamath Falls County Medical Society in March at Klamath Falls by Dr. Charles C. Tiffin, Seattle, at which more than forty cases of goiter were presented.——At the March meeting of the Portland Academy of Medicine, Portland, Dr. Hyman B. Meyers spoke on "The Comparative Toxicity of Volatile Oils Toward Yeast."——Dr. Blair Holcomb addressed the Portland City and County Medical Society, March 17, on "The Results of the High Carbohydrate Diet for Diabetes," and Dr. Isidor C. Brill on "Acute Febrile Anemia (a new disease)."

PENNSYLVANIA

Personal.—Dr. Percival J. Herman, Selinsgrove, was recently dinner host to the Snyder County Medical Society in Middleburg, on the occasion of his completion of fifty years in the practice of medicine.——Dr. Lloyd E. Wurster, Williamsport, has been elected president of the Roentgen-Ray Society of Central Pennsylvania.——Dr. James H. McClelland has been elected physician to the board of health of Grove City.

University Appointments and Promotions.—Dr. Eliot R. Clark of the University of Georgia School of Medicine has been appointed to the faculty of the University of Pennsylvania School of Medicine; Dr. David H. Bergey has been promoted to professor of hygiene and bacteriology; Horace B. Baker to be assistant professor of zoology; Dr. Morton McCutcheon to be assistant professor of pathology in the school of medicine; James C. Andrews to be assistant professor of physiologic chemistry, and Dr. Stanley O. Chambers to be assistant professor of dermatology and syphilology.

Philadelphia

Hospital News.—Mr. Samuel Rea, former president of the Pennsylvania Railroad, has accepted the chairmanship of the committee to raise $1,000,000 to enlarge and equip the Bryn Mawr Hospital at Bryn Mawr. There has been no enlargement to the hospital since it was built in 1893, excepting forty-four beds, while the population it serves has more than trebled.——Herbert Hoover, secretary of commerce, assisted in the ceremonies, April 15, of breaking ground for the emergency hospital for the Sesqui-Centennial exposition. The eight bed hospital will cost about $15,000.

Death of William Potter.—William Potter, for many years president of the board of trustees and president of Jefferson Medical College, died, April 29, following an operation. In addition to his great work at this institution, Mr. Potter's life was devoted largely to public service; he was appointed by President Harrison special commissioner to London, Paris and Berlin in behalf of the U. S. Postoffice Department, and was responsible for perfecting the international marine postoffice system; he went to Porto Rico for the government during the Spanish-American War; was United States Minister to Italy, 1892-1894, and was national fuel administrator for Pennsylvania during the World War.

Society News.—Dr. Isador C. Rubin, New York, addressed the Philadelphia County Medical Society, April 28, on "Sterility in the Female."—Dr. Paul D. White, Boston, addressed the Cardiac Clinics Committee of the Philadelphia Heart Association, April 27, on "The Prognosis of Angina Pectoris and Coronary Thrombosis."——Dr. S. Adolphus Knopf, New York, will address the Philadelphia County Medical Society, May 12, on "Mental and Physical Rest in Pulmonary Tuberculosis," and Dr. Howard Lilienthal, New York, on "Surgical Methods in the Treatment of Pulmonary Phthisis."——Dr. Harry Gideon Wells, Chicago, professor of pathology and chairman of the department, University of Chicago, will address the open meeting of the Bio-Chemical Society of Jefferson Medical College, October 15, on "The Chemistry of Immunity."——Withrow Morse, Ph.D., professor of physiologic chemistry and toxicology, Jefferson Medical College, addressed the annual meeting of the American Philosophical Society, April 22, on "The Metabolism of Uric Acid."——At the fifth annual meeting of the Philadelphia Heart Disease Association, April 13, the following officers were elected: president, Dr. George W. Norris; vice president, Dr. Henry K. Mohler; secretary, Dr. William D. Stroud.—— Dr. Temple S. Fay presented a case before the Philadelphia Neurological Society, April 23, of "Combined Glossopharyngeal and Cervical Posterior Root Resection for Pain from Carcinoma of the Throat."——Sir Arthur Newsholme, London, England, addressed a joint meeting of the Philadelphia Pediatric Society and the Section on Public Health and Industrial Medicine of the College of Physicians of Philadelphia, April 19, on "Some Remaining Problems in Maternity and Child Welfare."

TENNESSEE

Society News.—The annual meeting of the West Tennessee Medical and Surgical Association will be at Jackson, May 27-28, under the presidency of Dr. Eugene M. Holder, of Memphis; Dr. Isaac A. McSwain, Paris, has been secretary of this organization during its entire existence of more than thirty years.——The Chattanooga Medical Society invited the county court, the Chattanooga City Commission, representatives from each of the civic clubs, and the trustees of the Erlanger Hospital to meet with the society in the special session, April 22, to acquaint them with the various clinics and the health department; following a brief session of the society, the entire party visited the health department and the outdoor clinic at the Erlanger Hospital; brief talks on public health were arranged by the new advisory council, among the members of which are Dr. Ezekiel S. Blair, Apison; Dr. Alfred W. Gross, Sale Creek, and Drs. Leon T. Stem, Edward T. Newell, William D. Anderson, Samuel H. Long, and John B. Steel, all of Chattanooga.

TEXAS

More Medical Arts Buildings.—The *Texas State Journal of Medicine* notes that an eleven story medical arts building will soon be erected at Wichita Falls; a five story medical arts building at Corpus Christi, and a four story medical arts building at Abilene.

Personal.—Harry V. Atkinson, Ph.D., professor of pharmacology, University of Texas School of Medicine, Galveston, has resigned and accepted the position of associate professor of pharmacology at Iowa State University College of Medicine, Iowa City.——W. T. Dawson, M.A., associate professor of physiology, University of Texas, has been appointed associate professor of pharmacology.——Dr. Joel E. Wright, Alpine, has been elected health officer of Brewster County.

Illegal Practitioners Convicted.—Mrs. Addie Wise, Fort Worth, who is reported to have pleaded guilty recently to violation of the medical practice act, was fined $50 and sentenced to one day in jail; for years Mrs. Wise has advertised "Addawise" as a cancer cure.——H. Gordon Hargett, a chiropractor, was recently convicted at Fort Worth of the unlawful practice of medicine; Hargett claimed, it is reported, to have made no charge for the treatment, but admitted having accepted money from the patient's husband.

UTAH

State Medical Meeting.—The thirty-second annual meeting of the Utah State Medical Association will be held at Stewart Hall, University of Utah, Salt Lake City, May 6-8. It has been decided to eliminate discussions at this meeting, except as requested by the president, and to encourage the asking of questions within the time allotted for each address. Guests from other states include Dr. Anton J. Carlson, professor and chairman of the department of physiology, University of Chicago; Dr. Robert C. Coffey, Portland, Ore.; Roger S. Hubbard, Ph.D., Clifton Springs, N. Y.; Dr. Edmund Jacobson, research associate in physiology, University of Chicago; Dr. Dean P. Pratt, Henry Ford Hospital, Detroit; Dr. Edwin P. Sloan, Bloomington, Ill.; Dr. Charles C. Tiffin, Seattle, and Dr. Harry Gideon Wells, professor and chairman of the department of pathology, University of Chicago. A reception will be given in honor of the visiting ladies at the Hotel Utah, Friday. The postgraduate clinic week will be held later in the year.

VIRGINIA

Memorial to Walter Reed.—A commission appointed by the Medical Society of Virginia met in Richmond late in April and authorized the immediate purchase of the little frame building at Belroi, in which Walter Reed was born, as a memorial to the discoverer of the means of transmission of yellow fever. The building was built originally to shelter the overseer of the plantation on which it was located. At the time of Dr. Reed's death, it was a Methodist parsonage. The children of Virginia will be given an opportunity to contribute to the fund required to purchase and restore the building, which the Gloucester Chamber of Commerce, it is reported, has agreed to maintain. Whereas hundreds of people visit this shrine now, the commission believes that, when it has been restored, the number of visitors will be greatly increased. The members of the Walter Reed Memorial Commission are: Drs. Edward C. S. Taliaferro, Norfolk; Greer Baughman, Richmond; Clarence Porter Jones, Newport News; Halstead S. Hedges, Charlottesville, and Garnett Nelson, Richmond.

GENERAL

Fourth Colloid Symposium.—The fourth National Colloid Symposium will be held at Cambridge, Mass., June 23-25; among the speakers will be G. L. Clark, "Roentgen Rays and Colloids"; J. W. McBain, "A Survey of the Main Principles of Colloid Science," and G. S. Whitby, "Organophil Colloids."

Annual Directory of County Health Officers.—*Public Health Reports,* April 16, contains the annual directory of whole-time county health officers in the United States. There are 302 on the list while in the directory published last year there were 285. A whole-time public health officer is defined as one who does not engage in the practice of medicine or any other business, but devotes his whole time to his official duties.

Survey of Food.—The U. S. Department of Agriculture will undertake a survey in July to determine the kinds of food eaten throughout the United States, the quality and the quantities consumed in various sections. There is said to have been no adequate figures on food consumption available, and there is a demand for such information for scientific research and various other groups. It is planned to determine also whether an adequately nutritive diet is within the incomes of large groups of people. A committee will be appointed to conduct the survey.

Award of Leslie Dana Medal.—The National Committee for the Prevention of Blindness announces that the Leslie Dana Medal for the greatest achievement in the prevention of blindness and the saving of sight will be awarded to Miss Louisa Lee Schuyler, of New York. Miss Schuyler is said to have been personally responsible for the founding of the National Committee for the Prevention of Blindness; her interest in public health dates back to the Civil War, when she was an active leader of the Sanitary Commission. Last year the Leslie Dana Medal was awarded to Dr. Edward F. Jackson of Denver "for outstanding achievement in the organization of instruction in ophthalmological and medical colleges and for his contribution to the literature of ophthalmology."

Society News.—The second Pan-American Red Cross Conference will meet, May 25-June 5, at Washington, D. C. The New York chapter will meet all delegates on the arrival of their steamers in that port. The official headquarters will be at the Waldorf-Astoria in New York and at the Willard Hotel in Washington.——Dr. William G. Exton, Newark, N. J., was elected president of the American Society of Clinical Pathologists at the annual meeting, April 15-17, in Dallas, Texas; Dr. Arthur H. Sanford, Rochester, Minn., president-elect; Dr. James H. Black, Dallas, Texas, vice president, and Dr. Ward T. Burdick, Denver, secretary-treasurer.——Dr. Karl K. Koessler, Chicago, was reelected president of the American Association for the Study of Allergy at the annual meeting in Dallas, Texas, April 20, and Dr. Albert H. Rowe, Oakland, Calif., was reelected secretary-treasurer.

National Home for Disabled Volunteer Soldiers.—Established by an act of Congress soon after the Civil War, with a central branch at Dayton, Ohio, the National Home for Disabled Volunteer Soldiers now has branches also at

Milwaukee
Togus, Maine
Danville, Ill.
Hampton, Va.
Leavenworth, Kan.
Sawtelle, Calif.
Marion, Ind.
Hot Springs, S. D.
Johnson City, Tenn.

The Dayton, Milwaukee and Sawtelle branches have special units for tuberculous patients in addition to other facilities; the Johnson City and Marion branches are equipped to care for surgical conditions that may arise in connection with the work for which they have been especially designated, while all other branches have facilities for medical and surgical care of patients. When, in 1920, there was a demand for beds for mental and tuberculous patients, the Marion branch was converted into an institution for neuropsychiatric patients, and the Johnson City branch (which has 1,114 beds) was converted for the care of tuberculous patients. Persons that may be admitted to these homes on the order of members of the board of managers include honorably discharged officers, sailors or marines of the regular, volunteer or other forces of the United States, or of the organized militia or national guard when called into federal service, who are disabled by disease or wounds and who have no adequate means of support and who by reason of their disability are incapacitated from earning a living. Ex-service women honorably discharged from army, navy or marine corps may also be admitted; a portion of the Danville branch has been set aside for the domiciliary care of ex-service women, and a portion of the Milwaukee branch for those who have tuberculosis. The home is maintained by federal appropriations, and the President, the chief justice and the secretary of war are managers ex officio. Gen. George H. Wood, whose office is at the Central branch, Dayton, Ohio, is president of the home.

LATIN AMERICA

Personal.—The *Revista de Ciencias Médicas* of Buenos Aires relates that Dr. B. González has been elected governor of the province of Corrientes, and that Señora Elvira Rawson de Dellepiane, M.D., has been appointed member of the national board of education.——Dr. L. Velasco Blanco, Buenos Aires, is in the United States to attend the annual session of the American Medical Association at Dallas, Texas, and to be a delegate from Bolivia, his native country, to the Red Cross conference at Washington.——Dr. F. Banda has been made rector of the University of Guadalajara.——The president of Peru and Dr. S. Lorente, the president of the public health service and director of the Junta de Defensa de la Infancia, selected Dr. Paz Soldán to be director of the National Child Welfare Institute and training school for visiting nurses, recently inaugurated at Lima.

FOREIGN

British Association Sells Former Headquarters.—The New Zealand government has purchased the former headquarters of the British Medical Association on the Strand, London, for about £200,000, which, the London *Times* states, is the highest price yet obtained for property of that size on the Strand. The property is located where values have increased rapidly in the last two years.

Personal.—Prof. D. Giordano, president of the seventh International Surgical Congress, which convened at Rome, April 7, was accompanying Premier Mussolini to his carriage following the inaugural meeting which the latter had opened, when Mussolini was shot by an assailant. Giordano, it is reported, was responsible for diverting the aim so that the injury was not more serious. The *Gazette hebdomadaire des sciences médicales* relates that Professor Hartmann, president of the French section of the international society, introduced the resolution to readmit the surgeons of the central powers when the latter have been admitted to the League of Nations.——Dr. A. Missiroli is in charge of the Malaria Experimental Research station at Rome, which is partially financed by the International Health Board.——Our Paris exchanges state that Prof. A. Pettit of the Institut Pasteur, Paris, has been deputed by the French government to organize a similar Pasteur institute at Montreal at the request of the University of Montreal, of which it will be a department.——Prof. Martinez Vargas, Barcelona, presided at the recent tenth International Child Welfare Congress which recently closed its sessions at Madrid.——The University of Cologne has conferred an honorary degree on Prof. O. Lanz, Amsterdam.——Drs. E. Freund and G. Kaminer, Vienna, have been awarded the 1925 prize of the Austrian Anticancer Society.——Dr. M. R. Castex, professor of clinical medicine, Buenos Aires, gave an illustrated lecture on "Iodine Solutions in Exploration of Internal Organs" before the Berlin Medical Society, last month.——Dr. K. Sudhoff, professor of the history of medicine, Leipzig, has been elected to honorary membership in the Royal Society of Medicine, in London.——Professor Jeanneney, Bordeaux, has been sent by the French government to Italy to study the campaign against cancer there.——Dr. William Rankin has been appointed to the chair of surgery at the Anderson College of Medicine, Glasgow, Scotland, and Dr. S. Spence Meighan to the chair of ophthalmic medicine and surgery.——Dr. Charlotte Ann Douglas has been appointed to be a medical officer to the Scottish Board of Health, to succeed the late Dr. Mary J. Menzies.——Dr. William E. Gye, London, England, has been awarded the Walker prize by the Royal College of Physicians.

Deaths in Other Countries

Dr. T. **Jonnesco**, Bucharest, dean of the medical faculty, a pioneer in cervical sympathectomy and general anesthesia by intraspinal technic, aged 66.——Dr. D. M. **Mainini**, Buenos Aires, killed in an automobile accident.——Sir Harry Brookes **Allen**, professor of pathology and dean of the faculty of medicine, Melbourne University, Melbourne, Australia, formerly editor of the *Australian Medical Journal;* a member of the Central Board of Health; president of the Royal Commission on the Sanitary State of Melbourne; president of the Australian Medical Congress in 1908 and member of the executive committee, International Medical Congress, 1913, aged 71.——Dr. W. K. **Law**, brother of the late Mr. Bonor Law, at Londonderry, aged 73.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 16, 1926.

Opticians Attempt to Obtain Registration

After the osteopaths, the opticians have attempted to obtain recognition, with similar result. Mr. Chamberlain, the minister of health, received a deputation from the "Joint Council of Qualified Opticians," with which was associated the British Optical Association, to discuss a private member's bill to secure the registration of optical practitioners and to regulate the practice of sight testing and optical dispensing. The opticians claimed competence to deal only with errors of refraction and to detect functional abnormalities requiring specialist treatment by an ophthalmic surgeon, and it was a condition of the diplomas granted to opticians by their organizations that all cases of functional abnormalities should be referred to a medical practitioner. It was claimed that they had therefore done all that the minister, in speaking of Dr. Graham Little's motion about the registration of osteopaths in the House of Commons, had advised osteopaths to do, before claiming the right to prohibit unregistered practice. They had already established a college, a hospital and diplomas. Legislation similar to that which was proposed was already in force throughout practically the whole of the British Empire and the United States. The bill would be a protection against charlatans, and would put an end to the conflict of views that had arisen between the opticians and the physicians. The minister said that the bill as drafted would debar physicians from treating defects of vision. This was perhaps not an insuperable difficulty, but he doubted whether any amendment that would remove it would leave the bill in a form acceptable to the opticians. But the whole difficulty was that defect of vision might be due to simple errors of construction in the eye itself which can be corrected mechanically by glasses; to disease in the eye needing treatment apart from the provision of glasses; or diseases not localized in the eye but due to a pathologic condition in the body. If a case was not rightly classified, very serious injury to the patient might ensue. He was also not satisfied that the optical board, proposed in the schedule to their bill, would secure the qualification only of persons competent to recognize disease, and he pointed out that eighteen of the twenty-five members of the proposed board were to be opticians. It was not possible to argue from conditions in one country to those in another. Conditions in the dominions were entirely different. There were vast territories with relatively small and widely scattered populations that could not all be served by physicians. He admitted that he had some sympathy with their claim that persons who had properly qualified themselves to treat errors of refraction not requiring medical attention should have a special label, and he would like to meet this point. The difficulty out of which he could not see his way was how patients suffering from simple errors of refraction could be distinguished from those in whom defect of vision was due to some pathologic condition.

Death Registration Bill: Safeguard Against Concealment of Crime

A bill to amend the law relating to certification of deat and the disposal of the dead came before a standing con mittee of the house of commons. The object is to rende more complete the safeguards afforded by the law of regi tration in relation to the disposal of the dead, so as to eli nate as far as possible the risk of the concealment of

Provision is made for enabling local authorities to arrange for the medical inspection in certain instances of the bodies of deceased persons, and stillbirths are required to be registered as a measure of additional safeguard for the protection of infant life.

The Medical Aspect of Birth Control

The medical committee of the national birth rate commission is holding an inquiry into birth control. The terms of reference are as follows: 1. It is recognized that there are many aspects of the question of conception control; this inquiry is limited to its medical aspects. 2. In using the term "medical," it is intended to make an investigation into the restriction of families by whatever method it is accomplished and its effects on the bodily and mental health of the individuals concerned. 3. Under the term "health" are included the relevant biologic (physiologic and psychologic) factors that affect the normal life. 4. Among the particular problems which it is proposed to investigate are the effect on health of sexual abstinence, partial or complete, in married life, and the effect of the use of various contraceptives on the subsequent fertility and health of the persons concerned. The members of the committee include many well known persons in the medical world, including Prof. Leonard Hill, director of the department of applied physiology of the medical research council; Dr. A. E. Giles, gynecologist; Dr. Mary Scharlieb and Prof. F. H. A. Marshall of Cambridge University. The committee is sending out a questionnaire to gynecologists throughout the country and is to hear representatives of medicine and physiology.

Physicians and Publicity

Some controversy is going on in the lay press on the question of signed articles by physicians, in which the British Medical Association and the New Health Society figure. The official policy of the British Medical Association on the question of publicity in the profession is indicated in a report adopted at the annual meeting last July, of which the salient clause reads: "From time to time there are discussed in the lay papers topics which have relation both to medical science and policy and to the health and welfare of the public, and it may be legitimate, or even advisable, that medical practitioners who can speak with authority on the question at issue should contribute to such discussions. But practitioners who take this action ought to make it a condition of publication that laudatory editorial comments or headlines relating to the contributor's professional status or experience shall not be permitted; that his address or photograph shall not be published, and that there shall be no unnecessary display of his medical qualifications and appointments. There is a special claim that practitioners of established position and authority shall observe these conditions, for their example must necessarily influence the action of their less recognized colleagues. Discussions in the lay press on disputed points of pathology or treatment should be avoided by practitioners; such issues find their appropriate opportunity in the professional societies and the medical journals." The New Health Society agrees with the British Medical Association in the difficulty of prohibiting any contributions from the medical profession to the press which give advice or express opinions with regard to this or that method of treatment. It is impossible for an uninstructed public to estimate the real value of any such method. With regard, however, to the spreading of knowledge of the simple measures necessary for the preservation of personal health, the society considers the position to be very different. Such knowledge, it says, is now entirely agreed on by the medical profession, and if put into practice by the people at large the standard of health of the whole community would undergo an extraordinary rise, and knowledge of the laws of health would be spread far and wide.

BUCHAREST

(From Our Regular Correspondent)

April 3, 1926.

Auto-Infection from Vaginal Secretions

The normal vaginal secretion is antiseptic by virtue of its lactic acid content. The cervical secretion, on the other hand, is neutral or alkaline and forms an admirable culture medium for bacterial growth. Since the acidity of the vaginal secretion disappears during the puerperium, it seems a wonder that infection does not always occur. After experiments, Professor Marinescu concludes that the vaginal secretions during the puerperium destroy organisms by phagocytosis, and that bacteria existing in the passages before parturition can gain a foothold in the tissues only if the passages are injured during labor.

Regulation of the Purity of Food

The examination of foods and beverages is in the hands of an analyst, whose duty is limited to reporting on specimens submitted to him. He has no advisory functions, and he is not brought into contact with the local government board, whose control is, under present conditions, entirely nominal. Professor Ganea suggests that the local government board should employ an expert skilled in analysis and having expert knowledge of the manufacturing processes employed in the preparation of food and drink. Aided by a staff of trained inspectors, it should be his duty to exercise general supervision, not only over the sale of foods but also over their manufacture or importation. He should further lay down standards for the sale of foods and drugs, and the local government board could thus impose uniform standards on the various local authorities.

The Health of Bucharest

Computed on a yearly basis, the death rate in Bucharest in the last quarter of the preceding year was 18.7 per thousand. The mean rate during the corresponding periods of the last six years was 23.9. Apparently, the drop is due to the improvement in economic and financial conditions. A large proportion of the deaths in Bucharest are due to diseases of the respiratory system. The crux of the health question in Bucharest is, of course, the housing problem. The municipality and voluntary bodies are supplanting condemned tenements by sanitary dwellings. Their efforts are, however, on such a small scale as yet that they are only experiments.

An Unusual Case of Bradycardia

Dr. Schmidt showed a case of bradycardia in the Targulmure Medical Union. For three months the patient had suffered from peculiar attacks, which have increased in frequency, up to ten or twelve in a day. The patient becomes suddenly giddy, unconscious and pale, the head is stretched backward and the pulse slows to 48, 42 and 36. These attacks pass off in a short time. There is widening of the heart, the apex beat is heaving, and the first sound is dull, with a minimum capillary pulse. The symptoms of locomotor ataxia are progressing. All symptoms were dependent on a common cause: syphilis.

Rectal Feeding in Gastric Ulcer

In the *Praxis Medici*, Dr. Vasilescu has a paper on rectal feeding in gastric ulcer. He says that a wound heals the more rapidly the less its edges gape. An ulcer of the stomach heals the more rapidly, therefore, when the stomach is contracted. It is in a state of greatest contraction when hunger is felt. It has been shown clinically that human life can be sustained for weeks by rectal feeding. Kleinberger mentions a case in which a man was fed exclusively by the rectum for seventy days. No hyperchlorhydria is present in an empty stomach. The usual nutrient enemas do not excite gastric secretion, but it would be as well to omit red wine as an addition to the enemas. Vasilescu's patients were under treatment for two months. Altogether, two patients died. The weight, blood pressure and pulse curve sank moderately. The lowering of blood pressure did not usually exceed 30 mm. The hemoglobin appeared to diminish only when the bleeding continued. The erythrocytes remained constant or rose slowly. They sank only when hemorrhage was severe and continuous. Screen examination of the patients revealed that healing is quicker under extrabuccal treatment than by any other method.

History of Police Control of Prostitution

March 25, Dr. C. G. Cumston addressed the Geneva Medical Society, on "The History of Police Control of Prostitution from the Biblical Epoch to the end of the Eighteenth Century." The lecturer showed that prostitution was rampant in the days of the patriarchs and the prophets, but that the Hebrews never exercised legal control over it. Solon, in ancient Greece, was the first to give laws controlling debauchery; these were severe, as the lecturer showed by many quotations from the texts. Police control of prostitution was brought from Greece and Asia to ancient Rome by the armies, 189 B. C. Landlords of brothels were obliged to obtain a license from the ediles, and before exercising their profession courtesans were compelled to make a declaration of their intention to the ediles. The female inmates of public houses (*lupanaria*) were called "wolves" in order to show contempt. There were at this time forty-five brothels in different parts of Rome. The wolf who suckled Romulus and Remus and served as the emblem of Rome was a prostitute.

With the exception of Constantine (320 A. D.), the Christian emperors attempted to abolish prostitution, but without avail. Charlemagne, more powerful than his predecessors, made the first French law absolutely prohibiting prostitution and considering it a misdemeanor. The law is in the Capitularies (800 A. D.) and prescribes severe corporal punishment, not only of the offender but of the landlord of the house in which she lived as well.

During the feudal period, prostitution knew no bounds, not only in cities but also in the country, on account of soldiers who scoured the land. St. Louis, by his law of 1254, made a fruitless attempt to do away with this plague.

In 1161, parliament held at Westminster, in the reign of Henry II, delivered a decree regulating the bath houses, which were the rendezvous of prostitutes in those days. The lecturer stated that from his researches he was inclined to believe that this document is the first that refers to venereal disease.

Among the many decrees referred to by the lecturer may be mentioned that of the prefect of Paris, in 1360, prohibiting prostitutes from wearing fine clothes or jewelry, and in 1367 a decree obliging them to live in brothels and parts of the city allotted to them. Coming to the year 1802, we have the law of March 3, which, besides police control, for the first time orders periodic medical examination of prostitutes.

Hereditary Memory

Hereditary memory, as a subject recently discussed by Léon Daudet, is worthy of attention. According to Daudet, Bergson's intuitivism depends on the ancestral form of human memory residing in the cerebellum, which acts as a transferring and transforming agent. The few experiments so far undertaken on the cerebellum show that it is the mnemonic regulator (resulting from congenital memory) of the upright position, circular movements and, in general, of all special components of the human mind. It seems destined to transmit mental images derived from parents and ancestors to the real images of the living person. Hence the images will either be reinforced or dwarfed, if not interfered with, by congenital reminiscences belonging to the same category or to a closely allied category. In other words, Daudet admits in the waking dream a complete hereditary syndrome issuing from hereditary memory. The constant gravitation of the mind and the circulation of mental images explain how a jet of hereditary memory, reinforcing a present sensation, may procure us the aura of the future.

Hospitalization and Tuberculosis

Dr. Bauer of Neuchâtel delivered a remarkable address to the Swiss Antituberculosis Association at its recent meeting on "The Rôle of the Hospital in Antituberculosis Prophylaxis." In France the total number of cases of tuberculosis is 600,000 of which 150,000 are dangerous to others. In Switzerland, according to Ganguillet's statistics, there are, in all, about 50,000 tuberculous patients, 12,000 of whom are capable of infecting others. The ideal method of isolation of infectious tuberculous patients is hospitalization, but if carried out absolutely would present objections. The decrease of the morbidity from tuberculosis is in a way related to the number of beds placed at the disposal of these patients. Denmark, with a population of 3,300,000, has thirty-five tuberculosis hospitals (total, 1,016 beds), sixteen sanatoriums with a total of 1,385 beds, four asylums totaling 132 beds, and five establishments for convalescents, representing 3,458 beds. Hence, Denmark has 109 beds for each hundred deaths annually from tuberculosis. The number of tuberculosis cases in hospitals in 1921 was 8,044, and 70 per cent of deaths from this disease occurred—at least in Copenhagen—in hospitals. The total death rate from tuberculosis in this country has dropped to 9.44 per 10,000 inhabitants.

In France (40,000,000) there are fourteen tuberculosis hospitals, with a total of 2,995 beds. In the general hospitals the total number of beds reserved for tuberculosis cases is 4,296. Hence the total number of beds is 7,291, or eighteen beds per hundred thousand inhabitants. The latter figure does not include the beds in sanatoriums, as their number is not known. The total mortality from tuberculosis in France is 23 per 10,000 inhabitants.

In Switzerland, the number of beds in the many sanatoriums is not known. However, according to Ganguillet, the general hospitals have eighty-seven beds reserved for tuberculosis cases per hundred thousand inhabitants, and sixty-four per hundred thousand in the free public sanatoriums. There are about 250 indigent contagious cases per hundred thousand inhabitants. Hence the hospitals offer a total of 3,300 beds and the free sanatoriums 2,500 beds, a total of 5,800 beds. The death rate in Switzerland from tuberculosis is 16 per 10,000 inhabitants, making a total of 6,500 deaths. Therefore, generally speaking, the hospital treatment of patients is in a fairly satisfactory condition.

These few statistics are interesting, as they tend to prove that the death rate from tuberculosis is in a high degree influenced by hospital treatment of contagious tuberculosis. But many patients are prejudiced against hospitals. Propaganda by the medical profession would greatly help removing this prejudice. Finally, there is a category of "ultrachronic" cases that are contagious and in which hospitals can render useful, if only temporary, service, because continuous hospitalization for these patients is practically impossible. Two solutions offer themselves for the prophylaxis of these patients; namely, either to put them in hospitals for incurables or treat them at their homes under the supervision of dispensary physicians and send them to hospitals whenever the chronic tuberculous process shows signs of activity.

Social Insurance Lectures

The Committee on Social Medicine of the Young Generation of Czechoslovak Physicians held lectures on social insurance last month. As in most countries, the Czechoslovak medical profession and the insurance authorities have not always been in accord. The two parties differed on the aim which insurance societies are to fulfil.

Prof. F. Prochazka, in his introductory lecture to the series, described this conflict. The insured were less interested in the medical than in the cash benefit. Political parties, especially the social democrats, early used the officials of the insurance societies as political agents. As a result, very little of the funds remained for disbursement for medical services. The insurance system has reduced private practice to a minimum, but the income of the medical profession as a whole has been increased. At present, the medical profession is fighting for free organized choice of physicians instead of the present system of fixed medical officers of the insurance societies. In the discussion it was brought out that scientific and professional matters should be separated from financial considerations and the medical profession should be interested in both.

The second lecture was concerned with dispensaries. It is to the interest of specialists that the insurance dispensaries be limited. The objection that the medical profession brings forward against insurance dispensaries is that they obscure the individual and bring before the physician a mass of patients which he is seldom able to master. The medical profession would agree to the establishment of diagnostic dispensaries only when no treatment would be given except that which requires apparatus such as could not be installed in the private surgery of a physician. There is considerable diversity of opinion among physicians on this point. The group interested in preventive medicine holds that dispensaries make the services of a specialist available to patients who otherwise could not have them.

Prof. F. Hamza, in the third lecture, spoke on the rôle which insurance should play in preventive medicine. One of two courses can be followed: Either the insurance system can build its own institutions for combating disease or it can use and contribute to the dispensaries, sanatoriums, etc., which have been erected by other organizations. The second possibility seems to be the only logical one. Such a policy, furthermore, would aid many private institutions now in need of funds.

The subject of the next lecture was the establishment of chief medical officers in the insurance bodies. According to the law, physicians have no right to be represented in the official machinery of the insurance bodies. Thus, the advice of an expert in many purely medical questions was not available. As a remedy, some of the insurance bodies have appointed chief medical officers whose task it is to supervise the work of the medical officers and to render decisions in cases of doubt. This institution, for various reasons, has created friction, and the consensus was that it could be further developed. These medical officers should be employed by the insurance bodies on a full-time basis in order to avoid conflicts with practicing physicians.

The fifth lecture was given by V. Johannis, director of the Federation of Insurance Societies. Mr. Johannis always stood against the wishes of the physicians in insurance. It was the first time that a representative of insurance authorities appeared before a meeting of physicians in order to discuss with them the questions of insurance practice. Mr. Johannis announced a new spirit which is slowly gaining ground in the insurance scheme and which puts medical benefit ahead of other interests. At present the insurance societies are confronted with the enormous cost of remedies prescribed by the physicians. This is due to waste in prescribing. Owing to overcrowding, insurance officers prescribe without thorough examination in order to get rid of patients as quickly as possible. Consequently, patients have come to expect as many medicines as possible. The prescribing of "patent medicines" in recent years has further increased this item. Another source of wastage is that many of the insured go to the physician knowing that they do not need medical treatment but with the object of obtaining a cash benefit. Such a patient discards medicine given to him. This whole problem, according to the lecturer, lies in the hands of the insurance medical officers. Although he did not speak directly about free choice of physicians, he declared it impossible for the present to increase expenditures by new arrangements. As old age and invalidity insurance will go into effect, July 1, fees paid by the insured will be cut down.

Another lecture dealt with medical activities in accident insurance, and another one presented a scheme for the reform of the pensions insurance system. The conclusions arrived at in the meetings were embodied in the form of resolutions. The general tone of the discussion between the conflicting interests was conciliatory.

Ministry of Health

The political crisis of March 18 brought about the resignation of the minister of health, A. Tucny. The program that he announced at the time of his entry into office favored the medical element in the ministry of health. In the new cabinet, no minister of health was appointed and the minister of social welfare, J. Schiesl, was charged with the direction of the ministry of health. This measure does not mean yet the abolishing of the ministry of health but is unquestionably a step in this direction. A ministry, according to the constitution, can be abolished only by a special law. A few days ago it was announced that the clerical party had submitted to parliament a law for abolishing the ministry of health which has a great chance of being accepted. Although protests will be registered against this measure, especially from the medical profession, those who could follow closely the work of the ministry of health agree that combination with the ministry of social welfare is a sound measure. The fields of these two ministries overlap, and consequently many disputes ensued which hampered the work. The new minister is strongly in favor of combination of the two ministries.

Conference on Relationship of Social Insurance to Preventive Medicine

March 18, an international conference on the relationship of social insurance to preventive medicine was opened in Prague under the presidency of Dr. F. Boudrau of Ohio, who is at present assistant director of the health section of the League of Nations. The conference was attended by Dr. A. Foramiti of Austria, Dr. V. Chodzko of Poland, Dr. G. Gortway of Hungary and Dr. A. Savel of Germany. Czechoslovakia was represented by Dr. J. Riha. Drs. O. Olsen and E. Tomanek of the secretariat of the League of Nations and Dr. L. Mitchell representing the International Health Board of the Rockefeller Foundation also attended the conference. The conference drew up the outline of a study of social insurance and preventive medicine to be carried out by the representatives of the committee in the different countries. The study will be accompanied by an analysis of the health administration of the capitals of the states under study. The appraisal form prepared by the American Public Health Association for the study of municipal health departments will be used for this purpose.

Observations on the Habits of Ants

In the current number of the *Deutsche medizinische Wochenschrift*, Privatdozent Dr. Eidmann has an article on "psychic" or "mental" qualities of ants. In order to study the "language" of ants, Eidmann constructed a large upright ant-nest of plaster of paris, which was provided with glass walls, through which, as in a beehive, a captured large colony of *Myrmica rubra* (a common species in Germany) could be carefully observed and all the details of intercommunication noted.

If one puts a bit of food — for instance, a dead insect — in the vicinity of the ant-nest, only a short time will usually elapse before one of the workers ranging about, a "scout," will discover the booty. The worker, having convinced herself through the application of the antenna of the genuineness of the find, drags it off in the direction of the nest, where it is received and disposed of. But, if the scout is unable unassisted to manage her find, she returns to the nest to sound an alarm. Her mode of operation, on reaching the nest, is to run about in an excited manner, crossing antennae with all the comrades she chances to meet. The ants thus informed of the scout's discovery scurry forth in quest of the prize. In a short time, sufficient aid has assembled to accomplish the task of carrying the booty back to a place of safety.

To test the ant's sense of duty, the observer placed an enticing morsel, a bit of honey, in the path that was being worn between the dead insect and the nest. Tarrying only for a moment to take a sip of the honey, the ants continued their work, and did not consume the honey until their appointed task was completed.

The ant queen is enabled after impregnation to found a new colony unaided. This mode of colonization is referred to as being autonomous.

Eidmann observed the autonomous method of colonization among our largest species, *Camponotus ligniperdus* Latr. June 10, 1924, he placed a pregnant female in a small three-chambered, upright nest, made of plaster of paris. Here the queen shut herself off from the outer world by stopping the entrance to the lower darkened chambers of the nest with a wad of cotton. After a short time, she laid a bundle of fourteen eggs, from which the larvae were hatched. May 29, the first worker came forth. The nest was kept moist but up to this time, the queen had not partaken of food. Nevertheless, she had been able not only to satisfy the metabolic exchange of her own body but to raise a whole group of larvae. The queen was compelled to take the entire food consumption that she and her brood required from the reserves of her own body.

For the observation of the dependent form of colonization, Eidman placed a fertile female of *Formica sanguinea* Latr. in a large nest that contained a small colony of *Formica fusca* L., the common slave-ants, consisting of twenty workers and 100 pupae. After a short time spent in reconnoitering, the queen pressed forward into the lower chambers of the nest where the *fusca* workers were and where the pupae were stacked up. She incited the first worker she met to combat, and retreated to the upper chamber, followed by the enraged worker. Here she turned on the worker and promptly bit her to death. Immediately the queen rushed back into the lower chambers to renew the combat, and pursuing the same tactics had soon killed the superior force.

From the pupae that the queen now had in her possession, a large number of *fusca* workers developed, became her willing slaves, and assisted her in raising her own brood.

Marriages

ROBERT THEODORE LUCAS, Shreveport, La., to Miss Ruth Romaine Dudley of Plano, Texas, March 23.

GEORGE FRANKLIN FARMAN, Los Angeles, to Miss Mary Inslee Franklin of Tucson, Ariz., March 16.

ROYSE DAVIS, Decker, Ind., to Mrs. Elizabeth Oexmann of Vincennes, at Evansville, March 8.

Deaths

Lee Masten Francis ⊕ Buffalo; Rush Medical College, Chicago, 1901; member of the House of Delegates of the American Medical Association, 1920 and 1921; the American Academy of Ophthalmology and Oto-Laryngology (secretary, 1911-1918, president, 1919-1920), the American Ophthalmological Society, and the Buffalo Ophthalmologic Club; assistant professor of ophthalmology, University of Buffalo Department of Medicine; on the staff of the Buffalo General Hospital; served during the World War; aged 48; died suddenly, of cerebral hemorrhage, April 22, at Dallas, Texas, while attending the annual session of the American Medical Association.

Lucius Wales Hotchkiss ⊕ Santa Barbara, Calif.; Medical Department of Columbia College, New York, 1884; member of the American Surgical Association and the American Society of Clinical Surgeons; president of the Santa Barbara County Medical Society; professor of clinical surgery at his alma mater; consulting surgeon to the Roosevelt, Bellevue and Knickerbocker hospitals, New York, Greenwich (Conn.) Hospital, St. John's and St. Joseph's hospitals, Yonkers; aged 66; died, April 11.

Charles Stuart Moody ⊕ Rigby, Idaho; Central Medical College of St. Joseph, Mo., 1900; past president of the Idaho State Medical Association; for several years a member of the state legislature; Spanish-American War veteran; served as adjutant general for the state of Idaho and as major in the M. C., U. S. Army, during the World War; aged 56; died, April 22, following a cholecystectomy.

Berten M. Davey ⊕ Lansing, Mich.; Detroit College of Medicine and Surgery, 1905; past president of the Ingham County Medical Society; on the staffs of the State Industrial School Hospital, 1910-1921, St. Lawrence Hospital, 1924-1925, and Sparrow Hospital, 1914-1925; formerly member of the city board of health; aged 44; died, April 10, of lobar pneumonia.

Fred Julius Fassett, Los Angeles; Medical School of Harvard University, Boston, 1906; member of the Washington State Medical Association; served during the World War; formerly on the staffs of the Children's Orthopedic Hospital, Kings County Hospital and the General Hospital, all of Seattle; aged 49; died, March 24.

Elonzo A. Whitlow, Scottsville, Ky.; University of Louisville School of Medicine, 1907; member of the Kentucky State Medical Association; past president of the Allen County Medical Society; aged 49; died, April 3, at the Blackburn Hospital, Bowling Green, of a skull fracture received in an automobile accident.

Theodore J. Doerderlein ⊕ Chicago; Medical Department of the University of Illinois, Chicago, 1894; member of the Chicago Gynecological Society; on the staff of the Grant Hospital and formerly on the staff of the Deaconess Hospital; aged 54; died, April 7, of carcinoma of the stomach.

Lefferts A. McClelland ⊕ New York; Long Island College Hospital, Brooklyn, 1885; member of the American Academy of Ophthalmology and the American Laryngological, Rhinological and Otological Society; aged 62; died, April 12, at his home in Brooklyn, of cerebral hemorrhage.

George Bevan Hope, New York; Bellevue Hospital Medical College, New York, 1875; member of the Medical Society of the State of New York; medical superintendent of the Metropolitan Hospital and on the staff of the Harlem Hospital; aged 79; died, April 18, of heart disease.

Charles Francis Adams ⊕ Hackensack, N. J.; Homeopathic Medical College of the State of New York, 1884; served during the Spanish-American War, when he received the Congressional Medal; on the staff of the Hackensack Hospital, where he died, April 21, aged 69.

Charles H. Gubbins, Philadelphia; Medico-Chirurgical College of Philadelphia, 1888; formerly professor of pharmacy and materia medica at his alma mater; for many years on the staffs of the Willis Eye, and Polyclinic hospitals; aged 71; died, April 16, of cerebral hemorrhage.

Forrest A. Chenoweth, Winchester, Ind.; Medical College of Ohio, Cincinnati, 1886; member of the Indiana State Medical Association; formerly member of the county board of health; aged 68; died, April 14, of angina pectoris and lobar pneumonia.

Frank L. Lewis, Atlantic, Pa.; University of Pittsburgh School of Medicine, 1896; member of the Medical Society of the State of Pennsylvania; for sixteen years served as justice of the peace; aged 54; died, March 28, of pneumonia.

Hubert Wadlington Harris ⊕ Cleveland, Tenn.; University of Tennessee College of Medicine, Memphis, 1917; served during the World War; on the staff of the Speck Hospital; aged 31; died, March 29, following an appendectomy.

Jesse Leonti Bliss ⊕ Holyoke, Mass.; Columbia University College of Physicians and Surgeons, New York, 1896; for several years on the staff of the Providence Hospital; aged 55; died, April 11, of heart disease and arteriosclerosis.

Alexander MacNeill, Summerside, Prince Edward Island; McGill University Faculty of Medicine, Montreal, Que., 1883; on the staff of the Prince County Hospital; aged 73; died, February 7, of carcinoma of the pancreas.

Allen P. Banfield, Catlettsburg, Ky.; Eclectic Medical Institute, Cincinnati, 1876; member of the Kentucky State Medical Association; aged 75; died, April 16, at the King's Daughters' Hospital, Ashland, of pneumonia.

William Bruce Borror ⊕ Morgantown, W. Va.; University of Maryland School of Medicine and the College of Physicians and Surgeons, Baltimore, 1918; aged 46; was killed in his office, April 15, by an assailant.

David Nicholas Alcorn, Sierre Madre, Calif.; Medical Department of the University of Illinois, Chicago, 1892; formerly a practitioner in Wisconsin; aged 69; died, February 11, of chronic cholecystitis.

Maurice Budwig, Cleveland; Baltimore Medical College, 1898; member of the Ohio State Medical Association; formerly on the staff of the Mount Sinai Hospital; aged 49; died, April 19, of heart disease.

Carl F. Wolfer, Louisville, Colo.; University of Colorado School of Medicine, Denver, 1890; formerly member of the board of education; aged 71; died, February 3, at Boulder, of cerebral hemorrhage.

Robert Bennie ⊕ Sault Ste. Marie, Mich.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1891; on the staff of the Memorial Hospital; aged 63; died, March 29, of pneumonia.

David Henry Keller, Los Angeles; Bellevue Hospital Medical College, 1890; formerly a practitioner in Chicago; served during the World War; aged 58; died, March 22, following a long illness.

Asher C. Taylor, Duluth, Minn.; University of Michigan Medical School, Ann Arbor, 1874; member of the Minnesota State Medical Association; aged 78; died, April 21, of cerebral hemorrhage.

John Montague Rose ⊕ San Francisco; College of Physicians and Surgeons of San Francisco, 1912; aged 57; died, April 19, of cardiovascular renal disease and bronchopneumonia.

Daniel Holton Eaton, Kalamazoo, Mich.; University of Michigan Medical School, Ann Arbor, 1905; member of the Michigan State Medical Society; aged 46; died, April 11, of pneumonia.

Isaac Lewis Potter, Ackley, Iowa; State University of Iowa College of Medicine, Iowa City, 1871; Chicago Medical College, 1877; formerly a druggist; aged 80; died, April 4, of influenza.

August Edward Greene, Vincennes, Ind.; Medical College of Evansville, 1882; formerly secretary of the board of health of Harrisburg, Ill.; aged 66; died, April 7, of heart disease.

Frederick Schmidt, New York; Cornell University Medical College, 1900; member of the Medical Society of the State of New York; aged 52; died, March 20, of cerebral hemorrhage.

Charles G. Forbes, Washburn, N. D.; University of Michigan Medical School, Ann Arbor, 1886; also a druggist; aged 60; died in April, of heart disease and pneumonia.

James Alfred Pinkerton ⊕ Traer, Iowa; State University of Iowa College of Medicine, Iowa City, 1886; aged 65; died suddenly, April 14, at Iowa City, of cerebral hemorrhage.

Julius Weiss, San Francisco; Medical Department of the University of the City of New York, 1881; aged 67; died, April 2, of cerebral hemorrhage and arteriosclerosis.

Harry Benton Crawford, Beulah, Colo.; Drake University College of Medicine, Des Moines, 1896; aged 61; died, January 27, of carcinoma of the liver and pancreas.

Eli Samuel Beary, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1878; formerly a druggist; aged 75; died, April 8, of heart disease.

David Edward Dudley, Savannah, Ga.; Medical College of Ohio, Cincinnati, 1893; aged 55; died, March 20, at White Bluff, of acute nephritis and acute myocarditis.

John Baxter McLean, Fort Worth, Texas; Vanderbilt University Medical Department, Nashville, 1879; aged 72; died, March 4, of pneumonia, following influenza.

Willis O. Hubbard, Lowville, N. Y.; University of Buffalo Department of Medicine, 1882; member of the Medical Society of the State of New York; died, April 16.

James Hall, Wann, Okla.; College of Physicians and Surgeons, Keokuk, 1880; Civil War veteran; aged 86; died, April 4, of pneumonia following influenza.

John Whitehead ⊕ Salisbury, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1880; aged 70; died suddenly, April 15, of heart disease.

Malachi Coghlan, *Tensaw, Ala.; University of Alabama* School of Medicine, Tuscaloosa, 1892; aged 65; died in December, 1925, of organic heart disease.

William O. Dunlap ⊕ Sedalia, Mo.; St. Louis Medical College, 1875; aged 82; died, April 17, at the Robinson Sanitarium, Kansas City, of general debility.

William Cole Harrison, Los Angeles; Medical Department, University of Louisiana, New Orleans, 1882; Civil War veteran; aged 84; died, March 27.

Charles J. Lockhart, Owensboro, Ky.; University of Louisville School of Medicine, 1876; member of the Kentucky State Medical Association; died, April 6.

Chandler Robbins ⊕ Boston; Medical School of Harvard University, Boston, 1904; aged 47; died, April 6, at his home in Weston, Mass, of pneumonia.

Lemuel Cornick Shepherd ⊕ Norfolk, Va.; Bellevue Hospital Medical College, New York, 1886; aged 62; died, April 4, of a self-inflicted bullet wound.

Thomas J. McMurtry, Boxley, Ind.; Indiana Medical College, Indianapolis, 1875; aged 84; died, March 25, of pneumonia and heart disease.

William C. Quincy, Lowell, Ind.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1889; aged 77; died, April 1, of paralysis.

George E. Ricker, Wethersfield, Conn.; Hahnemann Medical College of Philadelphia, 1878; aged 83; died, April 4, of cerebral hemorrhage.

Dwight J. Harris, Evanston, Ill.; University of Michigan Medical School, Ann Arbor, 1864; Civil War veteran; aged 88; died, March 23.

Alice Bush, Oakland, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1891; aged 63; died, January 13, at Shanghai, China.

John Thomas Masterson, Moulton, Ala.; Pennsylvania College of Medicine and Surgery, 1870; aged 80; died, Dec. 15, 1925, of influenza.

Charles W. Culp, Mammoth Spring, Ark.; Memphis Hospital Medical College, 1885; aged 67; died, April 8, of cerebral hemorrhage.

George W. Holt, McLeansboro, Ill.; University of Louisville School of Medicine, 1876; aged 77; died, April 11, of chronic nephritis.

Louis William Grossmann ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1901; died, April 12.

Lemuel Franklin O'Bryant, Breckenridge, Mo.; Barnes Medical College, St. Louis, 1901; aged 50; died recently, of endocarditis.

John A. Wilkinson ⊕ Hales Corners, Wis.; Milwaukee Medical College, 1902; aged 66; died, April 10, following a long illness.

William F. Crickard, Delaware, Ohio; Cincinnati College of Medicine and Surgery, 1874; aged 74; died, April 4, in Columbus.

John Francis Spearman ⊕ Sharon, Pa.; College of Physicians and Surgeons, Baltimore, 1912; aged 36; died, April 4.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

KOCH'S "CANCER ANTITOXIN"

The Present Status of the Nostrum Exploited by William F. Koch

In 1918, William F. Koch of Detroit was graduated in medicine by the Detroit College of Medicine and Surgery. Previous to this he had been an assistant in physiology and an instructor in histology in the University of Michigan Medical School. He also had been professor of physiology in the Detroit College of Medicine and Surgery. Less than a year after his graduation in medicine, Dr. Koch announced that he "had developed a real specific cure for cancer." Dr. Koch's thesis seems to be that cancer is caused by a microorganism resembling the spirochete of syphilis. It is claimed that he has developed a differential poison—"Koch's Synthetic Anti-toxin"—that will destroy the "cancer germ" without injuring the host. His remedy has been described in one place as "a synthetic chemical compound of very definite molecular arrangement" and in another place as a "difficultly prepared synthetic structure, worked down on a recrystallization process"—two descriptions that make up in sonorousness what they lack in clarity.

Reproduction (reduced) of an advertisement in a recent classified telephone directory. The "Dr. Fleener" is apparently the same individual who for years ran quack advertising offices in other Indiana towns.

Seven years have passed, during which time Dr. Koch has seen fit to keep his secret to himself. During that same time we have been unable to learn of a single instance in which a case of unquestioned malignant disease has been cured by the Koch treatment. On the other hand, we have received information regarding individuals who "promptly died" after taking the treatment.

At different times the Wayne County (Detroit) Medical Society has appointed three committees to investigate Koch's "cure." Each of the three reports has been unfavorable. The last report closed with the statement:

> "In no instance have we found a case where the diagnosis of cancer was absolutely established and where no other form of treatment had been used in which a cure or any decided benefit had ever been obtained."

These facts have been discussed at different times in THE JOURNAL, and the matter is available in reprint form to any who will send a self-addressed, stamped envelop for it. The Koch treatment has been commercialized, and it seems evident that large sums of money have been spent in circularizing the profession and the public in the interest of the "cure."

SOME REPORTS FROM THE FIELD

During the last four or five years THE JOURNAL has received hundreds of letters from physicians and laymen who were inquiring about the Koch remedy. A few of the many letters from physicians and one from a layman made specific mention of individuals who were taking or were thinking of taking the Koch treatment for malignant disease. Recently we collected these letters from the files and wrote to those who had sent them asking for information regarding the outcome of the various cases. We have received answers from most of those to whom we have written, and we give in as few words as possible the essential facts.

Mr. A., Michigan.—Wrote in February, 1924, that his sister was taking treatment for uterine cancer from Dr. Koch. Recorded in March, 1926, that his sister died in Detroit in April, 1924.

Dr. B., New York.—Had three patients who took the Koch treatment: (1) Woman with carcinoma of rectum; "received four injections, reactions were terrible. She did not improve but steadily became worse and died." (2) Elderly man with beginning cancer of stomach; was "given two treatments and promptly became worse and died." (3) A case of axillary carcinoma received many treatments: "Ultimate result was the same—death."

Dr. C., Louisiana.—Wrote in November, 1924, that a friend with cancer of rectum was taking the Koch treatment at Detroit. Reported in April, 1926, that patient died in August, 1925.

Dr. D., Louisiana.—Wrote in November, 1924, that a prominent citizen of his town with malignant disease was under the care of Dr. Koch. Reported in April, 1926, that patient died. Dr. D. adds: "This has been the fate of all [personally] known cancer patients treated with Koch cancer remedy."

Dr. E., Alabama.—Wrote in January, 1925, that several patients suffering from carcinoma were taking the Koch treatment. Reports April, 1926, "All the patients who received the Koch treatment are now dead."

Dr. F., Mississippi.—Wrote in January, 1925, that patient with carcinoma of the stomach had received the Koch treatment. Reported in March, 1926, that patient died five months later. Reports also in his last letter the case of man with carcinoma on the side of the nose; took Koch treatment in August, 1925; at the present time the cancer "is more than twice as large as it was at the time of the treatment." Reports also that another patient with carcinoma of the cheek received the first Koch treatment in August, 1925; the patient is now "down in bed and not expected to live."

Dr. G., Tennessee.—Wrote in February, 1925, of a woman with adenocarcinoma and metastases who took the Koch treatment. Reports April, 1926: "She grew gradually worse, as all such cases do, and died, June, 1925, which is about the allotted time we expected her to live regardless of the Koch treatment." Dr. G. adds, "We had another case here in the city that Dr. ——— [a disciple of Koch] treated and she died very promptly."

Dr. H., Tennessee.—Wrote in February, 1925, that a woman with carcinoma was taking the Koch treatment. Reports in March, 1926, "she died promptly."

Dr. I., New York.—Wrote in September, 1925, that a woman with advanced carcinoma was so desperately ill that he advised her to remain at home. She, however, obtained money with extreme difficulty and paid $300 for one injection. "Came home in a state of extreme exhaustion and died in a few days after her return." The same physician reports another case of a patient with sarcoma who had been given injections at the cost of $500. "He subsequently died after having been advertised as a cure."

Dr. J., Kansas.—Wrote in October, 1925, that a patient with cancer of the tongue had gone to the Koch Cancer Clinic at Detroit. Reported March, 1926, that patient was given one injection, paid a fee of $300, stayed in Detroit for twelve weeks, received another injection, paying $200, remained two weeks longer, then went home and died one week after reaching home. The same physician reports another case, that of a woman with cancer of the uterus on her way to Rochester, Minn, who was induced while in the Union Station at Kansas City to go to a Koch disciple, where she received the Koch treatment. She received three injections, paying $250, although she was "in poor circumstances." Died about one month after the third injection.

Dr. K., Nebraska—Wrote in May, 1925, that "cases of cancer in this vicinity have been treated by means of the (Koch) serum with no results." Reports in April, 1926, on three cases: (1) Sarcoma in boy of 14; took Koch treatment and died. (2) Patient with carcinoma of pylorus; took treatment and died. (3) Patient with carcinoma of rectum with metastases; took treatment and died.

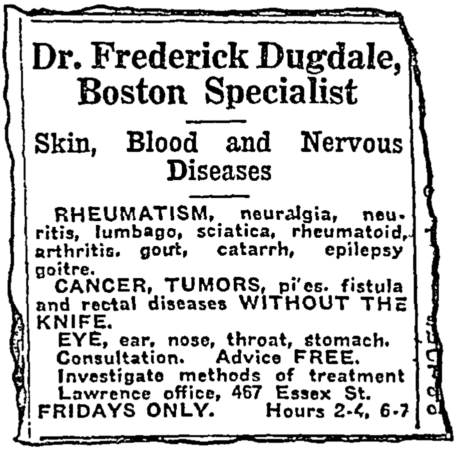
THE KOCH CANCER FOUNDATION

The latest move is the establishment of the imposingly named "Koch Cancer Foundation" with William F. Koch as "Director" This was organized in February, 1926, by the following individuals:

Frederick Dugdale, M D.
C. Everett Field, M D
A. W Hoyt, M.D.
W. Wallace Fritz, M D
Elvora C. Folkmar, M D.
Lorenz L. Dill, M D
Albert Lynch, M D

It may be of interest to present some of the information on file regarding these individuals:

Frederick Dugdale, M D, Boston—Dr. Dugdale was born in 1880 and was graduated in 1903 by the Baltimore Medical College. His activities in exploiting the Koch cancer cure are no matter of surprise When the large economic possibilities of the pseudoscience of Abrams were obvious, Dr Dugdale was one of the disciples of that cult Prior to that he advertised as a "Specialist in Rheumatism, Cancer, Chronic Blood and Nervous Diseases" In 1921 his name appeared as "President of the Allied Medical Association of America" (exposed in The Journal, July 5, 1919). It appeared also as one of the officers of the "Medical Society of the United States," which was originally created to organize fee splitters but later became a "Society of Protest Against the Autocracy of the A M. A." Still later Dr. Dugdale's name was given as Chairman of the Board of Trustees of the "American Association for Medico Physical Research" (exposed in The Journal, Sept 19, 1925)



Dr. Frederick Dugdale, Boston Specialist

Skin, Blood and Nervous Diseases

RHEUMATISM, neuralgia, neuritis, lumbago, sciatica, rheumatoid, arthritis, gout, catarrh, epilepsy goitre.

FRIDAYS ONLY. Hours 2-4, 6-7

A W. Hoyt, M.D, New York City—According to our records Alpheus Whiting Hoyt was born in 1866 and was graduated in 1895 by the Medical Department of the University of the City of New York. According to the September, 1921, issue of the house-organ of the late quack Albert Abrams, A. W. Hoyt was a disciple of the preposterous Electronic Reactions of Abrams and a lessee of one of Abrams' "Oscilloclasts" Dr Hoyt's professional cards read: "Treatment of Chronic Diseases," and he has sent out announcements stating that he had been "enabled to secure for his practice a medical treatment for what is called inoperable and incurable cancer" and "results warrant the statement that this treatment removes cancer from the incurable class of disease" More recently Dr Hoyt appears to have become interested in the "Auto Hemic Serum" of L D Rogers

W. Wallace Fritz, M D, Philadelphia—According to our records, W. W. Fritz was born in 1872 and was graduated in 1894 by the Medico Chirurgical College of Philadelphia This man sometimes puts after his name the letters M D, D D S, N D, D O, D C, indicating that he is a physician, a dentist, a naprapath, an osteopath and a chiropractor Added to these protean activities, he has been the "dean" of the "American College of Neuropathy" and "Professor of Neuropathy" at the same institution. It seems that when he became "dean" the institution had three students and thirty "faculty members." In 1915, the name of W. Wallace Fritz appeared as the "President of the National Association of Drugless Physicians" Dr. Fritz, for reasons not obvious, is permitted to hold membership in the Philadelphia County Medical Society, and, of course, has taken advantage of this to become a Fellow of the American Medical Association Nevertheless, in 1919, this man's name appeared in connection with the formation of a new organization that was to be founded to fight the American Medical Association—the alleged "medical trust" It was known as the "Constitutional Liberty League of America" and seemed to be a later edition of the defunct "National League for Medical Freedom" W W. Fritz's name has also been given as one of the "censors" and "vice president" of the "Allied Medical Association of America" He, apparently, was a witness in behalf of the quack Brinkler when the government was prosecuting this individual Brinkler, whose fraudulent business was debarred from the use of the mails in 1914 and also in 1916, was again quacking it through the mails in 1925, and his stationery last year declared that his "Medical Director" was W Wallace Fritz!

Lawrence (Lorenz) L. Dill, M D, Logansport, Ind—According to our records, Dr Dill was born in 1884 and received a diploma from the University of Michigan Homeopathic Medical School in 1910. He was licensed the same year. Early in 1924, Dr. Dill was puffing the Koch cancer cure It was not long before he was sending out printed cards bearing a map of Indiana that showed how Logansport might be reached and advertising the "Logansport Cancer Institute" According to these cards, Dr Dill was the "Director" of this "Institute" at which "Dr. Koch's cancer treatment is given" The opening paragraph of the card purports to answer the question "Can cancer be cured?" Dr Dill answers the question by analogy. He implies that the Koch nostrum has the same scientific value in the treatment of cancer that diphtheria antitoxin has in the treatment of diphtheria!

CAN CANCER BE CURED?

Can cancer be cured is a question which has been asked me many times not only by the laity but by the profession I recall one instance when the question was put to me by a Doctor in the following lines He said "Dr. Dill, can you cure cancer?" I answered him by asking him the following question, 'Doctor, can you cure Diphtheria? He said yes, in some cases It was quite evident to him then as to the position this treatment of Dr Koch's holds in the realm of cancer and sarcoma Then the following explanation was given as to the virtue of this treatment in the radication of cancer

C. Everett Field, M D, New York City—According to our records, Dr Field was born in 1870 and was graduated by the Medical Department of the University of the City of New York in 1891. He does not seem to have practiced until 1913—twenty two years after graduating. He is a member of his local medical society and as such has qualified as a Fellow of the American Medical Association Apparently Dr. Field was for some years connected with the advertising department of the

Glyco-Thymoline concern and later became president of the Holotheol Chemical Co. Still later he appeared as "director" of the "Radium Institute of New York." Becoming interested in the Koch nostrum, this product was given a great deal of newspaper publicity at the time that Dr. Field saw fit to puff it before the "American Association for the Study and Cure of Cancer." The latter organization is not to be confused, of course, with the well-established American Society for the Control of Cancer.

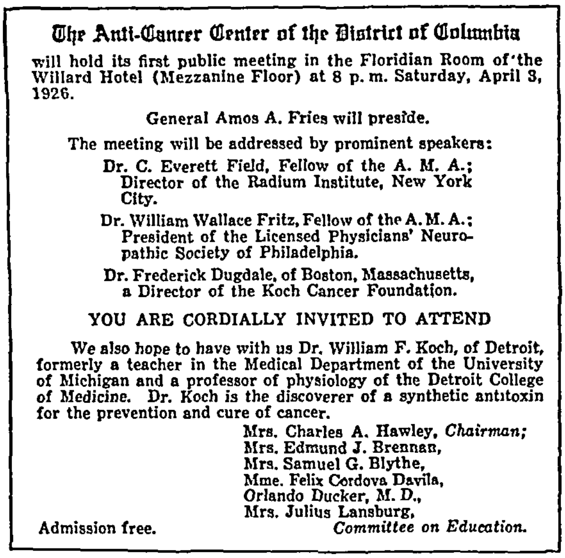
Elnora C. Folkmar, M.D., Washington, D. C.—According to our records, Dr. Folkmar was born in 1863 and was graduated in medicine when she was 46 years old by the George Washington University Medical School at Washington, D. C. In 1919, Dr. Folkmar appears to have been a member of the "Society of Physical Therapeutists," whose scientific status will be appreciated when it is known that on its program appeared the "patent medicine" exploiter George Starr White, the "zone therapy" exponent, Fitzgerald, and others who were to present papers on that preposterous piece of hokum "Bio-Dynamo-Chromatic-Diagnosis." Later Dr. Folkmar's name appeared as a lessee of one of Abrams "Oscilloclasts," and still later as the first vice-president of the egregious "American Association for Medico-Physical Research," which was dealt with in detail in THE JOURNAL, Sept. 19, 1925. Dr. Folkmar's name is also given in a booklet issued by D. V. Ireland (see THE JOURNAL, Dec. 2, 1922) as a specialist in the kind of rectal work taught by Ireland.

Albert Lynch, M.D., Fairbury, Neb.—Dr. Lynch was born in 1869 and received a diploma from the University of Michigan Medical School in 1901. Dr. Lynch seems to have been connected with the Koch organization early in the game, for a booklet purporting to be the report of an investigation by C. Everett Field, which was sent out two or three years ago, stated that Dr. Albert Lynch with Dr. Lorenz Dill, Dr. C. Everett Field and Dr. William F. Koch comprised the "committee" which at that time constituted the organization of "Koch Chemical Treatment Administration."

So much for the personnel of the founders of the Koch Cancer Foundation. There has also been organized "Koch Laboratories, Inc.," which is the sole owner and manufacturer of what Koch calls his "antitoxin." The incorporators of the Koch Laboratories are:

WILLIAM F. KOCH, President and Director
LOUIS KOCH, Vice President and Director
FRED C. KOCH, Treasurer and Director
CLARENCE LEHR, Secretary and Director

The Koch Laboratories, Inc., is evidently well controlled by the Kochs. Mr. Clarence Lehr, the secretary, seems to hold some interesting theses. Some are expressed in a letter recently written by him to a physician in Oklahoma. According to Mr. Lehr, "the American Society for the Control of Cancer is simply the sales agency for the surgeons of this country."



The Anti-Cancer Center of the District of Columbia

will hold its first public meeting in the Floridian Room of the Willard Hotel (Mezzanine Floor) at 8 p. m. Saturday, April 3, 1926.

General Amos A. Fries will preside.

The meeting will be addressed by prominent speakers:

Dr. C. Everett Field, Fellow of the A. M. A.; Director of the Radium Institute, New York City.

Dr. William Wallace Fritz, Fellow of the A. M. A.; President of the Licensed Physicians' Neuropathic Society of Philadelphia.

Dr. Frederick Dugdale, of Boston, Massachusetts, a Director of the Koch Cancer Foundation.

YOU ARE CORDIALLY INVITED TO ATTEND

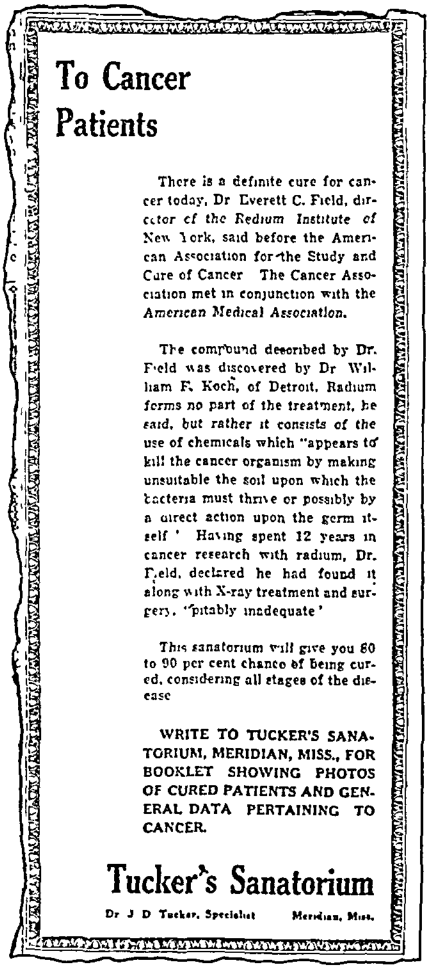
We also hope to have with us Dr. William F. Koch, of Detroit, formerly a teacher in the Medical Department of the University of Michigan and a professor of physiology of the Detroit College of Medicine. Dr. Koch is the discoverer of a synthetic antitoxin for the prevention and cure of cancer.

Mrs. Charles A. Hawley, *Chairman;*
Mrs. Edmund J. Brennan,
Mrs. Samuel G. Blythe,
Mme. Felix Cordova Davila,
Orlando Ducker, M. D.,
Mrs. Julius Lansburg,

Admission free. *Committee on Education.*

More publicity for the Koch nostrum. Note how fellowship in the A. M. A. is capitalized.

It is said that there is a contract between the Koch Laboratories and the Koch Cancer Foundation whereby "the antitoxin will be distributed through the Foundation only to *its Stockholders and Members.*" *Further, the* price of the treatment from the Foundation shall be $110 to both stockholder and member. According to a statement made by Dr. J. W. Stiers of Muscatine, Iowa (who in 1924 was said to be using an apparatus put out by the "Electronic Research Laboratories" and is now apparently using the Koch "antitoxin"), the Foundation "specifies as a *minimum* $300 for the first treatment and $200 for any afterward." The difference between the price charged the Koch disciple ($110) and the price the disciple charges the victim ($300) is presumably to cover the risk assumed by the followers of Koch in injecting a secret *mixture* into the cancer patient.



To Cancer Patients

There is a definite cure for cancer today, Dr Everett C. Field, director of the Radium Institute of New York, said before the American Association for the Study and Cure of Cancer The Cancer Association met in conjunction with the *American Medical Association.*

The compound described by Dr. Field was discovered by Dr William F. Koch, of Detroit. Radium *forms no part of the treatment, he said, but rather it consists of the* use of chemicals which "appears to kill the cancer organism by making unsuitable the soil upon which the bacteria must thrive or possibly by a direct action upon the germ itself ' Having spent 12 years in cancer research with radium, Dr. Field, declared he had found it along with X-ray treatment and surgery. "pitably inadequate '

This sanatorium will give you 80 to 90 per cent chance of being cured, considering all stages of the disease

WRITE TO TUCKER'S SANATORIUM, MERIDIAN, MISS., FOR BOOKLET SHOWING PHOTOS OF CURED PATIENTS AND GENERAL DATA PERTAINING TO CANCER.

Tucker's Sanatorium

Dr J D Tucker, Specialist Meridian, Miss.

Drumming up business for the Koch antitoxin.

The by-laws of the Koch Cancer Foundation provide that only physicians "whose qualifications have met the approval of the Board of Trustees" and who have "treated ten or more cases of cancer by the use of Koch's Synthetic Antitoxin" shall be eligible to become stockholders. The stockholders pay $100, for which one share of stock is issued. "Membership" in the Foundation is to be limited to physicians who are "able to furnish personal and *business* [Italics ours.—ED.] references satisfactory to the Board of Trustees." Such individuals may become members on the payment of a membership fee of $10 and annual dues of $5. Dr. Koch states further that in addition to the funds that will come into the treasury of the Foundation from the sale of treatments, membership fees and annual dues, he expects to purchase "upwards of $50,000 worth of stock." It is stated further that the "foundation" will from now on "attend to sending out all publicity, pamphlets, literature and the like" and that it is sufficiently financed to carry on the work vigorously for some time to come.

The publicity activities of the Koch Cancer Foundation have already begun to function. The press agent seems to be one V. E. Scott. Mimeographed material is being sent out from New York to the newspapers of the country, prepared in the form of news articles for "immediate release." The headlines are so worded as to catch the eye of any who may be interested in the subject of cancer and especially so as to disguise the advertising feature of these unpaid advertisements. Some of the claims that the newspapers are asked to print in the form of news regarding the Koch treatment are:

> "Dr. Koch's antitoxin has successfully cured more than 80 per cent of hitherto hopeless cases."
>
> "One injection is all that is needed in 90 per cent of the cases. We have found that the antitoxin cures every form of cancer and does so with remarkable speed."
>
> ". . . the Koch Cancer Foundation, whose physicians have successfully cured more than 80 per cent of hopeless cancer cases during the past two years with the antitoxin discovered by William F. Koch, Ph.D., M.D., of Detroit."

Here, then, is a piece of publicity material puffing a commercially exploited secret remedy which the newspapers of the country are expected to broadcast without charge. In this, a public that is ignorant of the facts is told that a "former Professor of the University of Michigan" (which Koch never was) has a remedy for cancer that will cure 80 per cent of hopeless cases with a single injection!

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SUTURE MATERIAL FOR CONJUNCTIVAL WOUNDS

To the Editor:—Is there anything new in the way of suture material for use in closing wounds of the conjunctiva, as in pterygium operations or in accidental wounds? What material do the best men use for this purpose? Have you ever noticed that a modern textbook says nothing about the very thing you want to know?

John J. McIntosh, M.D., Mount Carmel, Ill.

Answer.—Suture material is much like the Rock of Ages, unchanged by time. For closing conjunctival wounds, whether accidental or intentional, silk is still the suture material of choice; the color of the silk is a matter of individual preference. Solutions of continuity in the cornea or sclera still unite most favorably with silk sutures. However, under certain circumstances, such sutures may be under considerable tension that parallels the lines of cleavage of the tissues in question and, in order to prevent cutting through, it may be advisable to tie the sutures over the perforated gold plates first proposed by Wiener of St. Louis. For muscle operations, no. 0 catgut is frequently employed. In the last Torok and Grout Surgery of the Eye, one paragraph is devoted to suture material and its sterilization.

EPINEPHRINE IN CARDIAC ASTHMA

To the Editor:—I have a patient with cardiac asthma who is relieved by hypodermic injection of epinephrine. The injections leave ecchymoses or hematomas, however, and these red places remain sore for some time. Is there any treatment? Hobart P. Shattuck, M.D., Los Angeles.

Answer.—Epinephrine injections should be given intramuscularly, not hypodermically. When injections are given in concentrated form into the subcutaneous tissue, which is poorly supplied with blood, by reason of vasoconstrictor action, local nutritional disturbances and even necrosis occur. Great dilution would lessen this tendency. If the injections that produce the disturbances were given intramuscularly, dilutions of the solution would lessen the tendency to injury.

EYE-WASH FOR REMOVING CHEMICALS

To the Editor:—I would appreciate information concerning the proper emergency solution antidotal or neutralizing in action to be used in washing from the eye various chemicals, such as acids, alkalis and potassium cyanide. Please state strength of each solution.

Malcolm Raymond, M.D., Lansdowne, Pa.

Answer.—It is obviously impossible to give specific antidotes for the various irritant solutions that may attack and injure the eyeball. In general, it may be said that time and the quantity of the neutralizing solution used are more important than the character of the neutralizing solution. When the eye is attacked by a chemical irritant, the solution enters the tissues of the conjunctiva and cornea very rapidly, and unless the neutralizing agent is employed within the course of a very few seconds (less than one minute), the resultant injury is well under way. All that can then be accomplished is to wash away the excess, and for this purpose, at least one quart should be used. If the irritant is an acid, as occurs not infrequently in handling storage batteries, the best neutralizing solution is made by adding from two to four teaspoonfuls of ordinary baking soda to a quart of water. If the irritant is an alkali, the handiest neutralizing agents are milk or boric acid solution. But, as was stressed previously, it is not the character, but rather the quantity, of the neutralizing agent that is of major import.

STRENGTHENING THE HARRISON NARCOTIC ACT

A bill to strengthen the Harrison Narcotic Act of Dec. 17, 1914, as amended, and for other purposes, S. 4085, was introduced in Congress, April 24, at the instance of the Treasury Department. The purpose of this bill, says Assistant Secretary of the Treasury Andrews, is "to clear up certain points which have been raised in certain courts to the disadvantage of the government." These points are to be cleared up (1) by requiring collectors of internal revenue to refuse registration to physicians whom they believe narcotic addicts; (2) by requiring pharmacists to determine whether physicians' prescriptions were or were not issued in the course of professional practice, and to refuse to fill such as the pharmacist may reasonably suspect of not having been so issued; (3) by compelling physicians to keep records of every dose of any narcotic dispensed by them, except such as may be dispensed in emergency cases; (4) by forbidding everywhere the ambulatory treatment of narcotic addicts; (5) by requiring physicians to keep records of all purchases of so-called exempt narcotic preparations, and (6) by denying registration for a period of from one to two years to any physician convicted of any violation of the Harrison Narcotic Act.

Any collector of internal revenue, if this bill is enacted, must refuse to register under the Harrison Narcotic Act any narcotic addict. No preliminary notice and hearing are required. No grace is granted the unfortunate addict undergoing treatment in the hope of cure. Discretion is not allowed the collector. A narcotic addict cannot register, and the collector must act on such evidence as he has. The physician refused registration is left to redress in court, with all the publicity and loss of professional prestige which that procedure entails.

The laws of many states already provide that licenses to practice medicine may be revoked if the licentiate is a narcotic addict. The Treasury Department presumably has knowledge of addicts holding such licenses, or it would not have asked the right to refuse registration to such persons. Its field officers, however, instead of being charged with the duty of initiating action before state licensing boards looking toward the revocation of such licenses, are expressly instructed not to do so. That the disclosure of the information they possess is not unlawful is shown by the fact that they may disclose it on request of a state licensing board. But the Treasury Department keeps these boards in darkness. Why it thus refuses to avail itself of existing agencies effectually to bar narcotic addicts from practice, while it seeks authority to accomplish the same end to a limited extent through this legislation, is difficult to understand. The only guess that can be hazarded is that while the evidence of addiction in possession of the Treasury Department may satisfy some lay collector of internal revenue, vested with arbitrary power, as to the habits of would-be registrants, it would be of doubtful value if submitted to an impartial tribunal of physicians, when the registrant could introduce evidence on his own behalf.

The fact that Congress may not have authority to confer on the Treasury Department the power it here seeks does not seem to have occurred to those who drafted this bill. To determine who is and who is not fit to prescribe, administer and dispense narcotic drugs is to regulate the practice of medicine, whether that determination is based on supposed narcotic addiction or on any other grounds; and the regulation of the practice of medicine within a state is beyond the power of Congress. The United States Supreme Court states the case thus:

> The declared object of the Narcotic Law is to provide revenue, and this court has held that whatever additional moral end it may have in view must "be reached only through a revenue measure and within the limits of a revenue measure." Congress cannot, under the pretext of executing delegated power, pass laws for the accomplishment of objects not entrusted to the federal government. . . . Obviously, direct con*trol of medical practice in the states is beyond the power of the federal* government. Incidental regulation of such practice by Congress through a taxing act cannot extend to matters plainly inappropriate and unnecessary to reasonable enforcement of a revenue measure.—*Linder* v. *United States,* 268 U. S. 5, decided, April 13, 1925.

Every prescription issued by a physician for a narcotic drug will be subject to review by any pharmacist who may be called on to fill it, if the pending bill is passed. If there are present "circumstances from which the dealer might reasonably deduce that the prescription was not issued by the physician, dentist or veterinary surgeon in the course of his professional practice only," the pharmacist cannot lawfully fill it. It is not necessary that the pharmacist actually deduce that the prescription was not issued in the course of professional practice; it is sufficient that he might reasonably do so. What constitutes "the course of professional practice only," the bill does not state. It presumes apparently that any pharmacist can determine in his pharmacy what took place in the sickroom or in the physician's office, and that he is sufficiently acquainted with the normal course of professional practice to be entrusted safely with statutory authority to refuse to any sick person medicine that the attending physician has prescribed.

The pending bill provides that every physician shall keep a record of all narcotic drugs he dispenses or distributes, no manner how small the amount may be, except in emergency cases. The law now does not require the physician to keep a record of the narcotic drugs he dispenses or distributes in the course of his professional practice to patients on whom he is in personal attendance, except the so-called exempt narcotic preparations. The Treasury Department, it is true, undertook at one time by regulation to require physicians to keep records of narcotic drugs dispensed to office patients. The United States Circuit Court of Appeals, Eighth Circuit, however, April 14, 1922, denied the right of the department to impose any such requirement (*Hurwitz* v. *United States,* 280 Fed. Rep. 109).

A physician cannot, if the pending bill is enacted, dispense or distribute narcotic drugs pursuant to the so-called ambulatory treatment of narcotic drug addiction. Here again, apparently, the proponents of this bill have overlooked the right of each state to regulate the practice of medicine within its own borders. If the federal government can through its taxing power determine who may and who may not prescribe narcotic drugs, by eliminating narcotic addicts or otherwise, it may in like manner determine who may and who may not prescribe drugs of any other kind. If, under its taxing power, the federal government can determine how narcotic addiction shall not be treated in the states, it may in like manner determine how every other disease may and may not be treated. If, then, the federal government can tell the people of the states who shall and who shall not treat them, and how they may and how they may not be treated, our state medical practice acts may soon be superseded by federal statutes.

Physicians who dispense the so-called exempt narcotic preparations must, if this bill is enacted, keep records of all purchases of such preparations, in addition to the records of sales, exchanges and gifts, which they are now required to keep. The additional burden of keeping a record of purchases may not be great. It may well be asked, however, what good is to be accomplished by such a record so long as the law allows any one to buy the exempt preparations without physicians' prescriptions and without identification.

Probably the most objectionable feature in the pending bill is the provision that any physician convicted of having violated any of its terms or any provisions of the Harrison Narcotic Act as it now stands will be absolutely denied registration for a period of one year from the first day of July next following the date of such conviction. This is in addition to the penalties now authorized by law, a fine not exceeding $2,000, imprisonment not exceeding five years, or both, in the discretion of the court. Fine and imprisonment are discretionary. The refusal of registration is not. If a physician overlooks the renewal of his registration on or before July 1, and without reregistration prescribes a narcotic on the following day, he has violated the Harrison Narcotic Act. If some narcotic field officer prosecutes the physician for this lapse, the physician may be convicted. The court may impose a minimum fine, or even suspend sentence. But under the proposed law, registration could not be granted to that physician for from one to two years after conviction. This proposed deprivation of the right to prescribe narcotics for from one to two years has greater significance than appears on the surface. It would vest in the Treasury Department almost unlimited power to force compromises of cases by physicians supposed by the department to have violated the law, no matter how flimsy the evidence of such violation might be. Physicians threatened with prosecutions and informed as to the uncertainties of court procedure, rather than face the possibilities of convictions and the certainty, in event of conviction, of deprivation of the right to use narcotic drugs in their practices for a year or two, would readily pay large amounts to the Treasury Department by way of compromise, as is authorized by law. By so doing they would avoid the possibility of conviction and the loss of the right to use narcotics. And the Treasury Department would thus avoid the necessity of having to prove its cases in court to the satisfaction of impartial juries.

The denial of the right to register under the federal law, proposed in this bill, apparently ignores the opinion of the United States Circuit Court of the Northern District of Georgia:

> But to prohibit a practicing physician from prescribing narcotics unless he registers, and then refuse to register him, would, to that extent, be to prohibit and regulate his practice of medicine, a thing within the province of the state, and not of the United States, and in contradiction of the revenue purposes of the act.—*Starnes* v. *Rose*, 282 Fed. Rep. 336, decided, July 21, 1922.

On the whole, this legislation seems to have been conceived in disregard of the fact that the "certain points which have been raised in certain courts to the disadvantage of the government" have been based on the constitution, which an act of Congress cannot alter. It seems to disregard the fact that the keeping of records by physicians will not automatically enforce the Harrison Narcotic Act, but that it can be enforced only through the energy and intelligence of the officers and employees of the Treasury Department assigned to that duty. It seems to disregard the fact that registrants who would unlawfully dispense or administer narcotic drugs would without compunction falsify their records. The medical profession yields to no class in its willingness to submit to burdens calculated to diminish narcotic drug addiction. Evidence is not available, however, to show that the burdens proposed by this bill would do so. Until such evidence is forthcoming, the medical profession may be expected to oppose the enactment of this bill.

State medical associations, county medical societies, and physicians may well communicate their views with respect to this bill to the President, the Secretary of the Treasury, the Committee on Finance of the Senate, and the Committee on Ways and Means of the House of Representatives, and to their respective senators and representatives.

Book Notices

ULTRA-VIOLET RAYS IN THE TREATMENT AND CURE OF DISEASE. By Percy Hall, M.R.C.S., L.R.C.P. With introductions by Sir Henry Gauvain, M.A., M.D., M.C., Medical Superintendent, Lord Mayor Treloar Cripples' Hospitals, and Leonard E. Hill, M.B., F.R.S., Director, Department of Applied Physiology and Hygiene, National Institute of Medical Research, London. *Cloth. Price, $3.75. Pp. 110, with illustrations.* St. Louis: C. V. Mosby Company, 1924.

Among the numerous publications springing from the present interest in actinotherapy, some are justified by their broad and comprehensive presentation of the subject as a whole, others by the indisputable experimental or clinical evidence of some important phase in this field of therapy. Hall's work is an incomplete and rather unconvincing presentation of some of the clinical aspects of ultraviolet therapy. After not less than four prefaces, chapters dealing with sunlight, heliotherapy, artificial light and ultraviolet radiation furnish a fairly comprehensive but much too brief presentation of the physics and physiologic action of ultraviolet energy. The chapter on artificial light especially lacks critical presentation of the subject, and its illustrations include at least one obsolete type of lamp, the "leucodescent" one. The chapters on the sources of ultraviolet rays are laudable for calling attention to the tungsten arc lamp, for this type of ultraviolet radiation has a distinctly high place in therapy alongside that of the mercury arc lamp. Chapters on ultraviolet rays in rheumatic disorders, in neurasthenia and in pulmonary tuberculosis illustrate without justification their treatment by the Bergoniè chair and by diathermy through the "condenser couch." Ultraviolet rays are praised for their efficiency "in obscure autointoxication when other methods of treatment have utterly failed." Various types of lamps used in America are labeled with their trade names instead of the generally adopted scientific names based on their construction. The case histories presented are too casual, and no clear-cut attempt to evaluate ultraviolet rays by using them alone has been made. Statements as to dosage are vague. The author refers to the erythema and then again to the patient's own sensations as a guide in treatment.

THORACIC SURGERY. The Surgical Treatment of Thoracic Disease. By Howard Lilienthal, M.D., F.A.C.S., Consulting Surgeon to Mount Sinai and to Bellevue Hospitals. Two volumes. Cloth. Price, $20. Pp. 1294, with 904 illustrations. Philadelphia: W. B. Saunders Company, 1925.

This is the most comprehensive treatise on thoracic surgery that has appeared in English. The work is essentially a record of the personal experience and present views of a leader in this field. His purpose is to give to the general medical profession a guide to the diagnosis of surgical thoracic diseases and the possibilities of their operative treatment. Chapters dealing with related specialties are included to give necessary collateral information. These include physiology, by Evarts A. Graham; roentgenology, by Leopold Jaches; general anesthesia, by William Branower; blood transfusion, by Reuben Ottenberg; the intravascular treatment of thoracic aneurysm with gold wire and galvanism, by William Chittenden Lusk, and the treatment of pulmonary tuberculosis by means of induced pneumothorax by J. Burns Amberson, Jr., and Andrew Peters. With the exception of these chapters, the material is the personal contribution of the author and is based on his great wealth of clinical material. After a chapter on general considerations is one on the physiology of the chest, by Graham. This is detailed and extensive, supplying the necessary foundation for a proper understanding of the problems of thoracic surgery. It is followed by a chapter on roentgenology by Jaches, which practically constitutes an atlas, presenting not only a valuable collection of roentgenograms of surgical diseases of the chest but also normal conditions from infancy to old age, and postural photographs and corresponding roentgenograms. Considerable space is devoted to pulmonary tuberculosis and particularly its treatment by induced pneumothorax. Surgery of tuberculosis is of constantly increasing importance, and it is essential that the surgeon should be thoroughly familiar with the indications, contraindications and technic of artificial pneumothorax, as this treatment often should precede any resort to surgery. The methods of treatment, whether by operation or otherwise, which the author has found most effective are given precedence, although as a rule other methods are offered and discussed. The work as a whole is excellently presented and enhanced by numerous photographs, drawings and roentgenograms. Some of these are in series, taken at varying intervals. The chapter on the esophagus is disappointing in that the pioneer and fundamental work on antethoracic esophagoplasty by such men as Lexer, Hirsh, Rehn and Ropke, Jianu, Fink, Enderlen and Hotz is merely mentioned, without being presented adequately. A number of the illustrations are so poorly reproduced as to be of little value, especially those in the chapter on the surgical treatment of angina pectoris. The illustrations from Jonnesco give no idea of the clarity and detail of the originals. On the whole, the volumes present a wealth of clinical information presented clearly and so as to be of great practical value to the general surgeon as well as to those limiting their work to this field.

Fresh Air and Ventilation. By C.-E. A. Winslow, Professor of Public Health, Yale School of Medicine. Cloth. Price, $2. Pp. 182. New York: E. P. Dutton & Co., 1926.

Popular conceptions in regard to the relation between air and health are to a large extent erroneous. As Winslow points out, the great mass of scientific material on this subject is buried in lengthy treatises or in publications that do not come within the scope of popular reading. For a number of years sanitarians have taught that the overheating of rooms is more important than any other one factor; but in practical ventilation this has been to a large extent ignored, and emphasis has been laid mainly on an adequate fresh air supply. The author of this little book has done a service in giving the layman an opportunity to understand the truth about ventilation, told in a logical, clear and concise manner, which should serve as a model for popular presentations of scientific studies.

ÉTUDE ANALYTIQUE ET SYNTHÉTIQUE DE LA SYMPATHECTOMIE PÉRIARTÉRIELLE APPLIQUÉE AU TRAITEMENT DES ULCÈRES CHRONIQUES DES MEMBRES INFÉRIEURS. Physiopathologie et résultats immédiats et éloignés de la denudation artérielle. Par le Docteur Guillermo Garcia-Diaz, de la Faculté de médecine de Paris et de Buenos-Aires. Paper. Pp. 281, with illustrations. Paris, Le François, 1925.

The author has made a study of 346 cases of chronic leg ulcers treated by periarterial sympathectomy. A part of this group is composed of hitherto unpublished cases. The first chapters deal with the history of the operation and with the morphology and physiology of vascular innervation. The technic of the instrumental arterial denudation is carefully presented. A number of excellent tables compiled from cases in the literature show the immediate and the late clinical results of periarterial sympathectomy in cases of ulcers of the leg, the toes, the instep, the foot, and amputation stumps. He discusses the accidents of this operation and the likelihood of their occurrence. These include operative wounds of the vessels, secondary rupture of an artery, arteritis with thrombosis, and local aggravation of the trophic lesions. The means of prevention of these sequelae generally are: (*a*) selection of a large accessible trunk; (*b*) use of sharp instruments, and (*c*) operative precautions in the handling of the adventitia. The physiopathology is fully discussed. The results of the operation gave 1.4 per cent mortality; 3 per cent aggravation of the condition; 42 per cent absence of improvement, and in 53 per cent a healing effect. The writer concludes from his study that periarterial sympathectomy is practically without value from the point of permanent results, and is able to accelerate cicatrization in only 30 per cent of the cases. He does not believe that the results of the operation of periarterial sympathectomy are brought about by an interruption of the sympathetic system and a resultant vasodilatation, but by a vasomotor reflex related to the sensory and not the sympathetic fibers. The term sympathectomy therefore should be replaced by the term "neurectomy." Periarterial neurectomy produces a local anular contraction and a peripheral vasodilatation in the affected limb and certain healing effects in half the cases. The operation cannot be considered curative for chronic ulcers of the lower leg. Since arterial denudation is related to healing by a reflex action at which the point of origin is an excitation by section of sensory nerves, it seems rational to search for an operation directed toward the sensory nerves of the extremity in order to produce these phenomena without serious operative risks. The author believes that in the light of recent researches the vasodilatory and healing effects perhaps will be obtained without surgical intervention but by the use of certain forms of electric therapy and light therapy. This well written book is a valuable and rational analysis of this subject, and is a clear landmark in the midst of the variable current literature on this matter.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Chemistry and Recent Progress in Medicine. By Julius Stieglitz, Chairman of the Department of Chemistry, University of Chicago. The Charles E. Dohme Memorial Lectureship of the Johns Hojkins University, School of Medicine. Second course, 1924. Cloth. Price, $1.50. Pp. 62. Baltimore: Williams & Wilkins Company, 1926. .

Lecture analyzing new products developed by chemists for medical use and chemical contribution to understanding of physiologic and pathologic processes.

Food, Nutrition and Health. By E. V. McCollum, Ph.D., Sc.D., Professor of Chemical Hygiene, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, and Nina Simmonds, Sc.D. (Hygiene), Associate Professor of Chemical Hygiene, School of Hygiene and Public Health, Johns Hopkins University, Baltimore. Cloth. Price, $1.50. Pp. 143. Baltimore, 1925.

Thoroughly practical brief book for layman or physician, simply and well written.

Nephritis. Standardization of Clinical Work in Hospitals and Regional Offices. Compiled by Philip B. Matz, M.D., Chief, Medical Research Subdivision. With the cooperation of the Group on Investigation and Research of the Medical Council of the U. S. Veterans' Bureau. United States Veterans' Bureau Medical Service, Clinical Bulletin No. 12. Washington, 1926.

Official publication to standardize diagnosis and treatment of nephritis, based on Christian's classification.

Handbuch der normalen und pathologischen Physiologie. Mit Berücksichtigung der experimentellen Pharmakologie. Herausgegeben von A. Bethe, G. v. Bergmann, G. Embden und A. Ellinger. Elfter Band. Receptionsorgane I. (E/III. Tangoreceptoren. Thermoreceptoren. Chemoreceptoren. Phonoreceptoren. Statoreceptoren). Paper. Price, 81 marks. Pp. 1062, with 236 illustrations. Berlin: Julius Springer, 1926.

Part of extensive German system of physiology.

Handbuch der Hals-Nasen-Ohren-Heilkunde. Mit Einschluss der Grenzgebiete. Herausgegeben von A. Denker und O. Kahler. Zweiter Band. Zweiter Teil. Die Krankheiten der Luftwege und der Mundhöhle. Paper. Price, 84 marks. Pp. 1068, with 394 illustrations. Berlin: Julius Springer, 1926.

Second volume of new German system of diseases of the nose and throat, handsomely printed and illustrated.

The Treasury of Human Inheritance. By Karl Pearson, F.R.S. Volume II. Anomalies and Diseases of the Eye. Part II. Colour-Blindness. By Julia Bell, M.A., M.R.C.S., L.R.C.P. Nettleship Memorial Volume. Eugenics Laboratory Memoirs, XXIII. Paper. Price, 45 shillings net. Pp. 267, with illustrations. London: Cambridge University Press, 1926.

Monograph on heredity of color blindness.

Animal Heroes of the Great War. By Ernest Harold Baynes. With an account of the writer, "The Man and His Enemies." By Owen Wister. Cloth. Price, $3.50. Pp. 307, with illustrations. New York: The Macmillan Company, 1925.

Well written story by a lover of animals who also did much for scientific animal experimentation.

Nouveau traité de médecine. Publié sous la direction de MM. les professeurs G.-H. Roger, F. Widal, P. J. Teissier. Fascicule XIX; Pathologie du cerveau et du cervelet. Cloth. Pp. 1016, with illustrations. Paris: Masson & Cie, 1925.

Part of a French system of medicine dealing with technical aspects of neurologic pathology.

Gastric Function in Health and Disease. By John A Ryle, M D, F R C P, Assistant Physician and Lecturer on Medical Pathology, Guy's Hospital Cloth. Price, $2 75. Pp 152, with illustrations New York: Oxford University Press, 1926

A reprint of the Goulstonian lectures published in the *Lancet* in 1925.

Sixty Years in Medical Harness or the Story of a Long Medical Life, 1865 1925 By Charles Beneulyn Johnson, M D Cloth Price, $3 Pp 333, with illustrations New York: Medical Life Press, 1926

Reminiscences of a midwestern physician educated at Ann Arbor.

Von den akut infektiosen Respirationsstenosen der Kinder insbesondere dem diphtherischen Krupp und ihrer Behandlung Von Dr Dionys Pospischill, Primararzt Heft 8 Abhandlungen aus der Kinderheilkunde und ihren Grenzgebieten Herausgegeben von A Czerny. Paper Price, 2 40 marks Pp 42. Berlin. S Karger, 1926

Methods of a Viennese hospital in treatment of diphtheritic stenosis .

Ueber die Agraphie und ihre lokaldiagnostischen Beziehungen. Von Dr. Georg Herrmann, und Prof Dr Otto Potzl Heft 35 Abhandlungen aus der Neurologie, Psychiatrie, Psychologie und ihren Grenzgebieten Herausgegeben von K Bonhoeffer Paper Price, 24 marks Pp 380, with 29 illustrations Berlin S Karger, 1926.

Monograph of interest to neurologists.

Sampling and Examination of Mine Gases and Natural Gas. By George A Burrell and Frank M Seibert Revised by G W. Jones U S Department of Commerce, Bureau of Mines Bulletin 197. A revision of Bulletin 42 Paper Price, 25 cents Pp. 108. Washington: Government Printing Office, 1926

Technical bulletin of interest to laboratory investigators.

Burke and Hare. Edited by William Roughead Cloth Price, 10 shillings, 6 pence net Pp 280, with illustrations Edinburgh William Hodge & Co, Ltd, 1921.

The report of the trial of the two most renowned body-snatchers of all time.

Yatren 105 in der Behandlung der Amoebenruhr Von Prof Dr. R Ruge, Marine Generalstabsarzt A D Heft 4, Behringwerk Mitteilungen Begrundet von E v Behring Paper Pp 46, with 38 illustrations Marburg Lahn: Behringwerke, 1925.

Technical monograph on treatment of amebiasis.

Untersuchungen über den Stoffwechsel des Kindes im Fieber. Von Professor Dr. W Birk Heft 9 Abhandlungen aus der Kinderheilkunde und ihren Grenzgebieten Herausgegeben von A Czerny. Paper. Price, 7 marks Pp 104, with 19 illustrations Berlin: S Karger, 1926

Studies of metabolism of feverish children.

Disease Prevention By Herbert H Waite, M D, Professor of Bacteriology and Pathology, University of Nebraska. Cloth Price, $4.50 net. Pp 667 New York Thomas Y Crowell Company, 1926

A mass of information, technical in language and presentation, suitable as a reference work.

Comparative Physiology By Lancelot T. Hogben, M A, D.Sc, Assistant Professor in Zoology, McGill University Cloth Price, $3 Pp 219, with 44 illustrations New York. Macmillan Company, 1926

Lectures given to medical students who have completed elementary physiology.

Die Geschlechtskrankheiten Leitfaden für Studierende und Aerzte. Von H Lohe, A o. Prof a d Univ Berlin Paper Price, 8 40 marks. Pp 213, with 75 illustrations Berlin S. Karger, 1926

Well printed and illustrated handbook on treatment of venereal diseases.

A Superficie de Contraste na Semiotica Cardio Vascular. Por Aguinaldo Lins. Prefacio do Dr. Manoel de Abreu Do Instituto de Sciencias. Paper. Pp 80, with 45 illustrations Pernambucana, 1925.

Monograph from Pernambuca on studies of findings in the mediastinal region.

Visual Field Studies By Ralph I Lloyd, M D, F.A C.S, Surgeon, N. Y Ophthalmic Hospital Cloth. Price, $6 net. Pp. 216, with 124 illustrations New York. Technical Press, 1926

Material from author's lectures to graduate students in ophthalmology.

Fifteenth Annual Report of the Trustees of the State Institute for the Study of Malignant Disease, for the Year 1925. State of New York, Legislative Document, No. 51 Albany, 1926.

Report of the Public Health and Hospitals Department for the Years 1923 and 1924, Western Australia. Perth, 1925.

Revocation of License on Account of Advertisement

(Doran v. State Board of Medical Examiners (Colo.), 240 Pac. R. 335)

The Supreme Court of Colorado, in affirming a judgment dismissing a writ of certiorari to review an order of the state board of medical examiners revoking the plaintiff's license to practice medicine in Colorado, says that it was charged that he had caused an advertisement to be published in a newspaper in that state, which advertisement contained a statement that he had professionally treated and cured a certain woman of ulcers of the stomach, whereas the statement was false and known by him to be so. The woman referred to testified that she had never been a patient of his, and that she had never authorized or permitted him to make use of her name or to reveal her alleged physical condition, as was done in that advertisement. He testified that he resided in Minneapolis and that his practice consisted principally in traveling about from town to town in several Western states, including the eastern part of Colorado, and that he advertised in advance the date on which he would be in each town to receive patients at the hotel where he stayed; that he did cause the advertisement in question to be published, but that such part of the advertisement about the woman got there without his knowledge—must have been inserted through some mistake of some one in his office. He admitted that she had never given him permission to use her name in any advertisement, and that he had not treated her for ulcers, but he maintained that he had given her treatment of some kind. There was no evidence in the record that the physician did not know the contents of the published statement when he gave it to the publisher, or that he made inquiry of any employee in his office in Minneapolis how or why the falsehood was inserted, and there was no evidence by any such employee that he had prepared the notice without suggestion or information from the physician. The board, in the absence of any enlightenment from the physician, could not well assume that an employee acted without instructions.

The court has set forth the substance of the testimony, not that the courts may or can pass on its sufficiency to sustain the findings of the medical board, but to illustrate the character of this physician and the kind of practice in which he was engaged. That such advertisement was false and misleading and was intended and calculated to secure patients and fees for the physician among the unwary and inexperienced persons suffering from disease is too apparent to need discussion; and that it was made for the purpose of procuring patients and fees for himself is a fair inference. If such conduct is not immoral, dishonorable and unprofessional, this court does not know what conduct of a licensed physician would come within the meaning of those words. An elaborate argument of counsel for the physician as to the meaning of these expressions was made to convince the court that they did not include the false and misleading statements in this advertisement. The board of medical examiners consists of reputable physicians appointed by the governor. They are supposed to know better than laymen the ethics of their profession and what constitutes reprehensible conduct that unfits one to engage or continue in the practice of medicine, but an average layman, the court apprehends, would not experience much difficulty in arriving at the conclusion that a physician who, without authority of his patient, reveals to the public through a newspaper the nature of the patient's disease, or falsely states that he has cured him of an ailment, in order to increase his practice and professional fees, is not a proper person to practice the healing art. If the question was one for the courts, it is probable that they would not disagree with the findings or conclusion, either of laymen or of members of the medical profession.

On this board of medical examiners was conferred the power to pass on such charges. There does not appear to have been any abuse of discretion on its part. The courts are not called on in such a case to pass on the weight or sufficiency of the testimony on which the findings of the board are based. There certainly was testimony to sustain its findings. Since the medical board had jurisdiction both as to the subject-matter of its inquiry and of the person of the physician, and, having, as the record showed, regularly pursued its authority, the district court was right in dismissing the writ of certiorari. This and other courts have repeatedly held that the object of certiorari is not to settle or determine disputed facts but to investigate and correct errors of law of jurisdictional nature, and, under the code of procedure, abuse of discretion. Rehearing denied.

May Be Prosecuted Under Medical Practice Act

(People v. Mills (Calif.), 240 Pac. R 296)

The District Court of Appeal of California, third district, in affirming a judgment of conviction of the defendant of violating the medical practice act of that state, says that the testimony tended to show that he was practicing a system of curing and healing the sick according to the method and procedure or system known as chiropractic and followed by chiropractors. It was contended that, not having a license from the chiropractic board, he should have been prosecuted under section 15 of the chiropractic act, and that, as prosecution under that section could only be in the justice's court, the superior court, in which he was convicted, had no jurisdiction of the case. But by section 18 of the chiropractic act no part of the medical practice act is repealed, save as to those portions which are in conflict with the chiropractic act, when applied to persons holding a license issued by the chiropractic board.

Again, it was contended that, as the defendant had no license from the chiropractic board, he might have been prosecuted in separate courts for the same act, one prosecution under the terms of section 15 of the chiropractic act and another prosecution under the terms and conditions of section 17 of the medical practice act, as amended. It was also contended that one holding a certificate to practice medicine under the medical practice act would be subject to prosecution for an attempt to follow the system of curing used by chiropractors without having a license from the chiropractic board, which would result in the following situation. A medical practitioner holding a medical license would be subject only to a maximum penalty under section 15 of the chiropractic act of a fine of $200, or by imprisonment in the county jail for not to exceed ninety days; whereas, the defendant, having no medical certificate and attempting to cure by the same system without having a certificate from the board of chiropractors, might be punished under section 17, as amended in 1917, and section 24 of the medical practice act, as added in 1917, by a fine not exceeding $600, or by a term of imprisonment in the county jail not to exceed 180 days, etc, and that therefore the sections are discriminatory. The court does not need to determine the correctness of this contention, because, if such is the effect of the chiropractic act, it would only result in the holding that section 15 of that act is invalid, in that it is made applicable to one class of persons and not to another.

Under the two acts, a complete defense to a charge of curing without a license is the introduction and showing by the defendant that he holds a license from either board. In other words, section 17 of the medical practice act is allowed to remain in full force and effect by the initiative measure known as the chiropractic act; to apply with full force and effect as fully and completely as it did prior to 1922 by the express terms of section 18 of the chiropractic act, to all unlicensed persons. Nor does the court think that there was any merit in the contention that the defendant was subject to different degrees of punishments in different courts, by reason of the difference in the terms of the two acts referred to. The court does not see any good reasoning in the contention that the defendant had been improperly convicted under an act which applied to him—one not holding any license—simply because he might also have been prosecuted in another court, or, in the justice's court, for the same act and a lesser penalty imposed.

Hearing denied by the Supreme Court of California.

Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Twentieth Annual Meeting, held at New York, March 30-April 1, 1926

(Continued from page 1381)

Appendicitis in Early Life

DR. EDWARD W. PETERSON, New York: In a group of sixty-two cases five occurred up to 1 year; five from 1 to 2 years, eight from 2 to 3 years; nine from 3 to 4 years; fourteen between 4 and 5 years; and twenty-one between 5 and 6 years. More than 75 per cent were acute. About 60 per cent of the patients had perforation or abscess. There were no deaths up to the third year in eighteen cases; two deaths between 3 and 4 years; two between 4 and 5 years, and two between 5 and 6 years, respectively. Appendicitis under 5 is not at all uncommon. Under 2 years of age, it is apt to be overlooked in all but the worst cases. In certain cases the onset is insidious and the clinical picture obscure, but the majority have a clear-cut clinical picture. Speaking generally, the diagnosis of appendicitis in childhood is easier than in adult life, as there are fewer things to be looked for. The tendency to early perforation and the disastrous symptoms that follow are due to the habit of administering purgatives without waiting to establish a diagnosis. The majority of cases, undiagnosed, go on to recovery. In an acute abdominal attack in a child, with vomiting and fever, appendicitis should always be thought of, and this suspicion confirmed or ruled out. The lamentably high mortality from appendicitis in children is due to methods of procrastination and giving purgatives. The mortality in these cases is 9.67 per cent. The frequency with which appendicitis has developed during tonsillitis and influenza or acute infections makes me always ready to blame the appendix and to consider the possibility of a hematogenous origin. The presence of concretions means faulty drainage, and is associated with more or less inflammation of the organ. Foreign bodies have been found, and also intestinal parasites in these appendixes. There seems to be a direct causative relationship between appendicular irritation and intussusception; the relationship between hernia and appendicitis should also be considered. A failure to examine young patients with acute abdominal pain, vomiting and fever is also responsible for the relatively large number of late cases seen by the surgeon. In some cases, examination under light narcosis is necessary to establish a diagnosis. The examination should include a rectal examination, because the appendix is often low down in the pelvis. In young patients the "point tenderness", nausea and vomiting, with rise of temperature shortly after the onset of the pain, is sufficient indication for a diagnosis. The white and differential count is not as reliable as in adult cases. The differential diagnosis may lie between appendicitis and pneumonia, or gastro-enteritis, or intussusception, pyelitis or pyosalpinx, or inflammation in an undescended testis. Appendicitis may complicate pneumonia, influenza, tonsillitis, typhoid and various infections. One should never be satisfied with a diagnosis of measles or tonsillitis in the presence of pronounced abdominal symptoms.

DISCUSSION

DR. FENWICK BEEKMAN, New York: We have found at Bellevue that acute appendicitis in children under 5 years of age is rather rare. Our youngest child was 20 months old. If a series of all ages in life is taken, it will be found that about only 2 per cent of cases occur under 5 years. In a series of children up to 12 years of age, the percentage in the first half decade of life will be from 10 to 15. In our series we had a death rate of from 33 to 35 per cent in the first half decade of life, compared with a mortality of 6 per cent in the second half decade. Localization of peritoneal inflammation is much less common in children under 5 years of age than it is in older children, as shown by the relatively higher proportion of cases with spreading peritonitis at this age. We find that under 1 year of age the most common intra-abdominal condition in children is some form of obstruction: intussusception or strangulated inguinal hernia. I differ also with Dr. Peterson in that he says making a diagnosis of an abdominal inflammation in a child of 5 or under is easier than in an adult. Vomiting is a common symptom in all gastro-intestinal conditions, and in the vast majority of cases it is not due to inflammation of the peritoneum but to gastro-enteritis, and it is therefore very easy for the parents or the family physician to give the usual remedy, castor oil, and I am perfectly willing to say that I think in ninety-five cases out of a hundred they are right in their medication.

DR. MARSHALL C. PEASE, New York: I cannot altogether agree with Dr. Beekman, for both acute and chronic appendicitis are fairly common in children—even in young children. That 100 per cent of the children coming into the hospital already have a perforation bears out the importance of the condition because that means that the diagnosis was not made as early as it should have been made. I do not altogether agree with Dr. Peterson that the diagnosis is so easy, and I would rather agree with Dr. Beekman on that particular point. A group of cases in which a mortality rate of 33 per cent, or higher, is commonly accepted should be a reminder that appendicitis not only does occur in young children but should also serve to emphasize the importance of making an abdominal examination for a possible appendicitis in cases with fever and vomiting before going on with the treatment. If an early diagnosis is made, the death rate will be no higher than in adult life, and any community that has a death rate of anywhere near 18 per cent or above for appendix operations ought to feel disgraced; and yet 35 per cent is the figure for young children. Sometimes an exploratory operation is necessary to find out exactly what the trouble is.

Differential Section of Trigeminal Root in Surgical Treatment of Trifacial Neuralgia

DR. BYRON STOOKEY, New York: From the theoretical standpoint, the fact that there are in the trifacial root and in the gasserian ganglion two distinct nerves, certain clinical facts may be deduced. Trigeminal neuralgia occurs in the thalamic division with rare exception. I have had five cases in which I have saved the thalamic division at operation, with no recurrence of the pain. The patients have been saved the development of keratitis and possible removal of the eye. From the accidental finding of this result, it would appear justifiable in patients having pain in the thalamic division to save the thalamic division and cut through the second and third divisions. It is in these zones that the pain arises and spreads to the thalamic. In this operation, if two or three years hence the patient has a return of the pain, a second operation can be done, cutting the thalamic division. Where the choice lies between having the eye intact, and the possibility of a second operation, the second procedure is the one of election.

DISCUSSION

DR. MARTIN B. TINKER, Ithaca, N. Y.: Dr. Stookey's suggestion of dividing only the portion of the root which supplies the nerve affected, the third division, seems well worth considering. I agree with him that secondary operations in these cases, if the first operation has been done properly, should be easier than the first. One sees a good many instances of distressing neuralgia in young persons, and it is desirable to save as much as is possible.

DR. JOHN L. ECKEL, Buffalo: Any method of procedure that will prevent keratitis and in many instances the loss of an eye, and at the same time have sensation of the conjunctiva retained is a big advance in the surgery of this particular disease. If we can, at the same time, save the motor division of the fifth nerve and thus prevent atrophy of the muscles of mastication, we have added much. As time goes on and more experience of this method is had, it may be possible to remove the offending branch in each case and leave the other two branches intact, as well as the motor nerve, and thus relieve the patient of the terrible pain of this affliction with a minimum amount of sensory change and with no danger of corneal ulcers and no atrophy of the muscles of mastication.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Acidified Milks: Review. H. K. Faber, San Francisco.—p. 395.

Light and A-Body.—Bloch says that exposure neither to carbon arc light nor to sunlight cures xerophthalmia. Light cannot replace the A-body or supply it to the animal organism. On the other hand, it follows from investigations reported on by Bloch that in addition to its hitherto recognized reaction, light is indispensable to the animal organism, in that the radiant energy of ultraviolet light is essential to various functions. This energy is absorbed by the organism partly by direct radiation and partly through articles of diet (that is, cod liver oil, the yolk of eggs, and, to some extent, milk) which are charged with it.

Ketosis and Respiratory Exchange in Children.—The results reported by Wilson et al. are based on data derived from measurements of the respiratory exchange of six children during the ketosis induced by fasting and by administration of low carbohydrate, high fat diets. The evidence adduced is in accord with the clinical observation that children are particularly sensitive to ketogenesis. It also suggests a tentative explanation for the exaggeration of this tendency in the group of children known clinically as "cyclic vomiters."

Salt Solution Intravenously in Acute Poliomyelitis.—In a very severe and seemingly fatal case of acute poliomyelitis Smith injected 40 cc. of a 30 per cent sodium chloride solution into the right femoral vein. The child recovered, and Smith feels that the life of the boy was saved by the therapeutic measures employed, as no one who saw him just before treatment believed it possible for him to live.

Insulin in Malnutrition.—Fischer and Rogatz report the results obtained in twenty-seven malnourished infants, who were given insulin. Of these, seventeen results were distinctly successful, with marked gain in weight and improved nutrition. Five cases were indifferent, showing no change during or after treatment. Four cases were confusing, so far as a change of formula was necessary during the period of trial. One child died in a state of acute intoxication, despite the persistent use of insulin intravenously. In those cases reported as successful, there were no changes in diet or in management, other than the use of insulin combined with 20 per cent solution of glucose, to which improvement could have been attributed. No ill effects from individual doses of insulin were observed. Insulin given in repeated small doses seems to have a cumulative effect, which culminates in a rise in temperature, anorexia and loss of weight.

Vaccination Against Pneumonia. — Vaccination by the Chicago Pneumonia Commission against pneumonia as a protective measure is recommended in institutions for foundlings; in hospitals for babies under 2 years of age; for all patients with measles and whooping cough who are cared for in institutions; for all patients quarantined in their homes during the winter months, and for patients with rickets, especially colored children.

Recurrent Rickets.—The conclusion drawn by Hess is that recurrences of rickets are very frequent, especially during the second year of life. Hence, specific therapy—whether cod liver oil or ultraviolet irradiation—should be continued after all signs and symptoms of rickets have disappeared. Furthermore, cod liver oil should be given not only during the first, but also during the second, winter. This is advisable particularly in regard to infants who have had rickets and who are, therefore, susceptible to a recurrence in the course of the subsequent winter.

American Journal of Pathology, Boston

2: 1-97 (Jan.) 1926

*Auricular Endocarditis of Rheumatic Origin. W. C. Von Glahn, New York.—p. 1.
Case of Rheumatic Aortitis with Early Lesions in Media. A. M. Pappenheimer and W. C. Von Glahn, New York.—p. 15.
*Compensatory Hypertrophy of Thyroid. VII. Influence of Iodine on Hypertrophy of Thyroid. L. Loeb, St. Louis.—p. 19.
"Malignant Thymoma": Case of Primary Carcinoma of Thymus. N. C. Foot, Cincinnati.—p. 33.
*Fate of Reacting Leukocytes in Tuberculin and Reinfection Reactions. F. W. Stewart, P. H. Long and J. I. Bradley, Boston.—p. 47.
*Persistence of Glomerular Circulation Following Occlusion of Renal Vein of Kidney in Cat. I. T. Zeckwer, Boston.—p. 57.
*Lipoid-Containing Cells in Spleen in Diabetes with Lipemia. S. Warren and F. Root, Boston.—p. 69.
*Primary Gelatinous Cylindrical Cell Carcinoma of Lung. W. Hueper, Chicago.—p. 81.
Supravital Study of Leukocytes in Allergic States: Comparison of Delayed and Immediate Intrapleural Anaphylactic Reactions. P. H. Long and F. W. Stewart, Boston.—p. 91.

Auricular Endocarditis of Rheumatic Origin.—Von Glahn is convinced that there occur in the endocardium of the auricle lesions which are distinctive, both grossly and histologically, of rheumatic endocarditis. The endocardium of the left auricle is more frequently the site of the lesions than that of the right auricle. In the series of nine cases studied, the left auricle was involved in approximately one third of the cases of rheumatic valvular endocarditis.

Compensatory Hypertrophy of Thyroid.—On the basis of a very large number of experiments, it is stated by Loeb that potassium iodide does not prevent or even diminish the hypertrophy of the thyroid gland in the guinea-pig, which follows extirpation of a great part of the thyroid gland. On the contrary, in all his experiments the average of hypertrophy was greater in the animals which received potassium iodide than in the control animals. There are, in addition to the amount of thyroid removed and the amount of iodine fed to the animals, other variable factors which influence the degree of hypertrophy following extirpation, such as seasonal changes. On the basis of these results a tentative explanation of the influence of iodine on the structure and function of the thyroid gland is given.

Fate of Leukocytes in Tuberculin Reactions.—Stewart, Long and Bradley are certain that evidence derived from their experiments points to the fact that in the tuberculin and reinfection reactions the reacting cells are sensitized, and in early stages of the reaction undergo necrosis. Treated with appropriate doses of antigen, they undergo early death. These first cells are gradually replaced by others, due probably to the presence of necrotic tissue. The newly emigrating cells are viable elements.

Glomerular Circulation Following Occlusion of Renal Vein.—Ligation and section of the renal vein of one kidney in cats result in congestion and edema followed by a clearly defined zone of necrosis in the periphery of the cortex, beneath which there is a zone in which tubules are degenerating and glomeruli remain intact. Zeckwer says that the persistence of glomeruli with destruction of tubules indicates that there is a certain independence of the glomerular circulation from that of the tubules.

Lipoid Containing Cells in Spleen in Diabetes.—Three cases of diabetes mellitus with large lipoid-containing cells occurring in the spleen are reported by Warren and Root and compared with eight others collected from the literature. Lipemia was present in all cases but one. The lipoid material in the cells, so far as can be judged from staining reactions, consists of cholesterol esters or related substances, or phosphatides. Fatty acids or soaps may also be present. The reticulo-endothelial system is probably involved in lipoid metabolism, and may perhaps selectively absorb cholesterol compounds or phosphatides. Arteriosclerosis appears to be associated with this condition. Lipemia, produced by a high caloric diet, by a poorly balanced diet or by the general cachectic state of the tissues in severe diabetes, may predispose to atheromatous degeneration in the arteries.

Primary Carcinoma of Lung.—The tumor in Hueper's case was a primary gelatinous cylindric cell carcinoma of the lung, starting from the alveolar epithelium. He feels that two cases reported by Helly and Löhlein as benign adenomas of the lung must be considered as primary gelatinous cylindric cell carcinomas of the lung starting from the alveolar epithelium. The finding of acid-fast bacilli in the sputum of a patient with gangrenous processes in the lung due to a carcinoma may sometimes lead to the wrong diagnosis of pulmonary tuberculosis.

Archives of Dermatology and Syphilology, Chicago

13: 301-464 (March) 1926

*Treatment of Neurosyphilis by Malaria. P. A. O'Leary, W. H. Goeckerman and S. T. Parker, Rochester, Minn.—p. 301.

Congenital Alopecia: Two Cases. E. A. Oliver and N. C. Gilbert, Chicago.—p. 359.
Morphologic Variations in Ringworm Species of Toes, Followed in Primary Cultures over Period of Years. F. D. Weidman, Philadelphia.—p. 374.
Erythema Elevatum Diutinum: Case. W. B. Trimble, New York.—p. 383.
*Sarcoid of Boeck: Three Cases. K. P. Frost, Los Angeles.—p. 389.
Ringworm of Scalp in Adult. Case of Kerion Due to Microsporon Audouini H. Fox, New York.—p. 398.

Treatment of Neurosyphilis by Malaria.—A report is made by O'Leary of the preliminary observations after a ten months' trial of a series of thirty-five patients with neurosyphilis who were inoculated with malaria plasmodia. Of twenty-four patients with frank paresis, 25 per cent showed a complete remission that allowed them to return to their former occupations within two months after the malaria was stopped; 37 per cent were definitely improved in one way or another, and two died, one as a result of malaria and the other six months later in convulsions. Thus far in the series, the "fever therapy" has had practically no effect on optic atrophy, gastric crises, persistent lightning pains with negative serologic findings, asymptomatic neurosyphilis and paresis sine paresi. The mental and physical symptoms were most favorably influenced by the treatment without change being observed in the objective findings. There have been no serologic changes in the blood or spinal fluid as yet. The use of arsphenamine, mercury or tryparsamide immediately after the malaria was attended with definite evidence of relapse from remission. The majority of the complications noted were transient and disappeared with the cure of the malaria, although complications attributable directly to the syphilis may cause some embarrassment. Myocarditis, nephritis, marked weakness or wild delirium may demand the cessation of treatment.

Sarcoid of Boeck.—Three cases of the Boeck type of sarcoid are described by Frost. Two of these show possible evidence of tuberculosis of the lung. In one, there is a healed process which shows only roentgenographically; in the other, there is a possibly more active process.

Relation of Albuminuria to Protein Requirement in Nephritis.—A study of the nitrogen metabolism of certain patients with acute and chronic parenchymatous nephritis has been made by Peters and Bulger in an attempt to determine to what extent protein lost as albumin in the urine can be replaced by food protein. The total urinary nitrogen of these patients was not a satisfactory measure of nitrogen catabolism. The nitrogen catabolism could only be estimated from the urinary nonprotein nitrogen, after proper allowance had been made for changes in blood and tissue nonprotein nitrogen and variations of body weight due to diuresis or accumulation of edema. By the administration of large amounts of carbohydrate and fat, it was possible to reduce the protein catabolism to from 0.5 to 0.7 Gm. per kilogram a day. If enough protein was given to cover the nitrogen catabolism plus an additional amount equivalent to that lost as albumin in the urine, nitrogen wastage could be prevented. Abnormally high blood nonprotein nitrogen was observed only when the nitrogen catabolism was relatively high and usually returned to the normal level as the clinical condition of the patient improved and the nitrogen catabolism diminished.

Oxygen Treatment in Pneumonia.—Sixteen patients ill with pneumonia were treated with oxygen by Barach, ten in the portable oxygen tent and six by a combination of rebreathing apparatus and nasal catheter. These patients were selected because of the presence of arterial anoxemia. Of the ten patients treated in the tent, seven recovered. The three who died all suffered from pneumococcus type III lobar pneumonia with pneumococcus type III in the blood stream. Of six patients treated with the more portable apparatus, four recovered. The value of oxygen treatment is felt to be supportive and not curative. In severe dyspnea with cyanosis, oxygen treatment has appeared to prolong life until such a time as the immunity mechanism was able to accomplish recovery.

Healing of Gastric Ulcers.—In two cases reported by Crohn et al. in which partial gastrectomy was performed for gastric ulcer, operation was timed to take place at the end of a course of preliminary medical treatment. The specimens removed showed these ulcers in the last stage of healing. In one case, roentgen-ray examination just before operation showed the disappearance of the niche that had been present. It is believed that the rapid regression of ulcers in the intermission period will explain many cases of negative finding at exploratory laparotomy in cases with a suggestive ulcer history. In a series of such cases in which operation was done at a later date during a recurrence of the symptoms, the patient showed definite ulcer. The failure to demonstrate the lesion of a gastric or duodenal ulcer at exploratory laparotomy may, therefore, be due, at times, to the fact that the operation is carried out at a period in the life cycle of an acute ulcer when rapid regression and healing have obliterated the ulcer crater and made the lesion impossible of discernment.

Acute Mercuric Chloride Poisoning.—Evidence is presented by Kohn which suggests that direct myocardial damage may account, in part at least, for early toxic death from mercuric chloride taken by mouth. In three severely poisoned patients, the leukocyte count reached 34,000 or higher in a few hours, and it is suggested that the degree of elevation of the leukocytes may be an index of the severity of poisoning, with an unfavorable prognosis when levels of from 30,000 to 40,000 are found. While it is not denied that sodium thiosulphate may have value in treatment, it is emphasized that it may fail to exert detoxicant action, and should not be administered to the neglect of established therapeutic methods.

Blood Phosphorus and Calcium in Nephritis.—A relatively high percentage of cases of chronic interstitial nephritis with muscular twitchings or convulsions analyzed by Schmitz et al. showed values for the calcium of the blood serum below 7 mg. per hundred cubic centimeters. There was no uniform inverse relationship between the level of the inorganic phosphorus of the serum and the calcium in different cases. In other words, the retention of phosphorus had a greater influence in some cases than in others. However, in individual cases there was a gradual fall in the calcium with a rise in the inorganic phosphorus. There is little doubt in the minds of the authors about the reliability of inorganic phosphorus retention as a prognostic sign in chronic nephritis, but the creatinine is equally reliable, and the retention appears to occur a little earlier than is the case with inorganic phosphorus.

Acute Febrile Anemia.—Brill relates the case of a woman who had been severely ill with vomiting, malaise and a feeling of weakness for two weeks when he first saw her. Within the following day or two, the patient sank very low, becoming listless and picking at the bed clothes. She became pale and a generalized edema developed. There were several attacks of severe pain in the region of the spleen. These came on suddenly and lasted several hours. A blood count showed 27 per cent hemoglobin (Dare); 1,250,000 red cells; 5,750 white cells, with 61 per cent neutrophils, 36 per cent lymphocytes, 2 per cent eosinophils, and 1 per cent basophils. One week later the hemoglobin was so low that an accurate reading could not be made, but was probably about 15 per cent. The erythrocytes numbered about 1,000,000, and the leukocytes about 5,000, with a differential count essentially the same as in the previous examination. Blood cultures were consistently sterile. There was a deathlike pallor, numerous petechial spots, and a glassy edema involving the entire body; no jaundice was present. The patient was in a stupor, with labored respiration of the sighing type. The tongue was swollen and ashy gray. The heart action was feeble; the lungs appeared to be flooded with edema. The liver and spleen appeared moderately enlarged to percussion, but neither organ could be felt under the ribs. The temperature varied between 100 and 101 F., with an occasional rise to 103. The pupils were dilated and reacted sluggishly to light; the knee and ankle jerks could not be obtained. Finally, blood transfusion was resorted to and surprising improvement in the patients's general condition followed. Ten transfusions were performed in about five weeks. The amount of blood given varied from 300 to 500 cc., and the intervals between transfusions varied from one day to one week. The blood rose steadily, so that within a week after the last transfusion a practically normal count was obtained. At the end of two months the patient was up and around, enjoying normal health.

Effect of Sodium Citrate Injections.—Joannides' studies on man and on the dog showed that the injection of sodium citrate does not usually increase the coagulability of the blood. Intramuscular injections are less dangerous than intravenous injections. A 3 per cent solution of sodium citrate, which is isotonic with blood, has been fairly well tolerated by a patient who received from 300 to 450 cc. intravenously. This practice, however, is discouraged. Intravenous injections of great concentrations of sodium citrate are dangerous because they cause immediate respiratory and circulatory collapse. Small, repeated hemorrhages apparently have no effect on the coagulation time. On the other hand, when larger amounts of blood are removed they cause an increased coagulability of the blood. Citrated blood transfusion under such conditions increases the coagulability of the blood still more. Injections of 0.2 per cent sodium citrate solution in a 0.75 per cent sodium chloride solution invariably decrease the coagulation time of the blood and cause no toxic symptoms if the citrate dose is within the subtoxic limits. Sodium citrate apparently disappears from the blood stream since the toxic symptoms produced by the salt disappear quite promptly. Sodium citrate used in amounts corresponding to those for blood transfusion is a useful drug. In larger amounts or concentrations it is dangerous.

Paroxysmal Dyspnea in Syphilitic Aortitis.—In eighty-two cases of syphilitic aortitis proved by necropsy to have the characteristic anatomic lesions, paroxysmal dyspnea was present only when associated with aortic insufficiency, hypertension or aneurysm of the root or arch of the aorta. It would seem, therefore, that paroxysmal dyspnea was not a symptom due directly to syphilitic aortitis. Nevertheless, Keefer and Resnik regard it as an important symptom in the differentiation between the aortic insufficiency of syphilitic and of rheumatic origin.

Intradermal Salt Solution Test in Cardiac Disease in Children.—In a group of forty-seven children with rheumatic heart disease or allied conditions, it was found by Olmstead that the disappearance time of intradermally injected salt solution was normal (above fifty minutes) in well compensated nontoxic cardiac disease, acute rheumatic fever and chorea. In cardiac decompensation with edema, shortening of disappearance time was limited to edematous and pre-edematous regions and was noted earliest in the dependent parts of the body. Decrease in disappearance time did not precede other clinical signs of impending decompensation with sufficient constancy to make the test of much value in predicting a break in compensation. In certain severely ill patients having a cardiac disease without decompensation there was a marked and nearly equal decrease in disappearance time in the arm and leg. The intradermal salt solution test was of value in this generalized or toxic group in rendering an unfavorable prognosis. The disappearance time picture characteristic of the toxic group was altered in the direction of that characteristic of the decompensation group, if cardiac decompensation developed. In two patients tested after death, the disappearance time in edematous parts was practically as short as during life, which demonstrated that, under these conditions, circulation of the blood was not necessary in the phenomenon of disappearance of intradermally injected salt solution.

Phenolsulphonphthalein Excretion in Obstructive Jaundice.—The phenolsulphonphthalein excretion was found by Abramson to be normal in fifteen cases of obstructive jaundice with a varied etiology. In all of these cases, there was no evidence of renal insufficiency.

Experimental Intraperitoneal Transplantation of Endometrial Tissue.—Intraperitoneal transplantation of endometrium has been studied by Jacobson in the rabbit and the monkey (*Macacus rhesus*). In a series of nineteen rabbits, when the operation was performed during estrus, it was successful in sixteen, or 84 per cent. In six rabbits so treated during the restful stage only one showed a "take." In six animals operated on during pregnancy, there were implantations in two, or 33 per cent. An increased vitality or "virulence" is suggested for rabbit endometrium during estrus. Ectopic endometrial growths in five castrated rabbits showed the same atrophic changes seen in the uterine cornua. The implants were invariably cystic adenomatoid structures, often multilocular, and were found on the broad ligament, vagina, uterus, urinary bladder and large intestine. Five *Macacus rhesus* monkeys were subjected to hysterotomy, curettage and intraperitoneal transplantation of the curettings. In four animals ectopic growths were produced, which were confined to the uterus and adhesions about it. Operative trauma was probably responsible for the localization of the implants in this region. In one monkey actively menstruating when killed, ectopic endometrial tissue on the uterus and in the ovary was also menstruating. The successful inoculation of the peritoneum of the rabbit and the monkey with their own endometrium, the general location of the growths produced, their histologic character, the manner of their development and their reaction to the ovarian hormone, Jacobson asserts, are all in favor of Sampson's theory of the origin of most cases of ectopic endometriosis in man.

Relation of Suprarenal Cortex to Thyroid and Thymus.—Recent experimental evidence is summarized by Marine as follows: Thyroidectomy hastens involution of the thymus. Gonadectomy delays this involution but does not cause regeneration. Suprarenalectomy not only delays involution of the thymus and lymphoid tissues, but also actually causes their regeneration. Thyroidectomy prevents this reaction even after combined suprarenalectomy and gonadectomy. Suprarenalectomy plus gonadectomy is a more powerful stimulus for thymus and lymphoid regeneration than either of these influences alone. The combined effect of these two factors results in certain lymphoid and thymus hyperplasia in rabbits and rats, which persists until regeneration of accessory interrenal tissue corrects the physiologic effect. The syndrome thus experimentally produced resembles status lymphaticus and is believed to depend mainly on a partial loss of certain functions in the interrenal and sex glands rather than of the chromaffin tissue. The normal and abnormal lymphoid and thymic hyperplasias of infancy and childhood are believed to be manifestations of a functional underdevelopment of the interrenal and sex glands of varying intensity. The so-called lymphatic constitution which underlies or accompanies exophthalmic goiter and Addison's disease also appears to be dependent on a partial suppression of certain functions of the interrenal and sex glands.

Extradural Spinal Hydatid Cyst Causes Compression Myelitis.—A case of echinococcus disease is reported by Hines in which the spinal cord was compressed by hydatid cysts that developed outside the dura mater. Recent cystic changes in the vertebrae and an old echinococcus cyst of the kidney were associated findings.

Oil of Wintergreen Poisoning.—The clinical and pathologic features of poisoning due to oil of wintergreen are described by Wetzel and Nourse, in connection with a complete review of all the cases so far reported. Fatal poisoning may be produced by relatively small amounts of methyl salicylate. Absorption of less than 15 cc. has repeatedly resulted in death. Vascular changes are the most prominent among the effects. Multiple subserous hemorrhages of the heart, lungs and meninges, and parenchymatous hemorrhages of the brain, lungs and kidneys are produced. An unusually extensive subdural hemorrhage occurred in the present case. The authors warn that particular caution should be exercised to prevent the indiscriminate use of pharmaceutical preparations containing oil of wintergreen.

Leukocytic Reactions in Exanthematous Diseases.—There seems to be an early reaction of the neutrophil leukocytes in all these diseases. This is most pronounced and most prolonged in scarlet fever. This is followed by a depression in number of these cells and even by an inhibition of their production or supply, most marked in measles. This depression is followed by a return to normal and to a moderate leukocytosis, most evident in smallpox, in which the local skin lesions apparently are responsible. The lymphoid cells, on the other hand, show an early depression in number, followed in every case by a definite curve of reaction, with lymphocytosis often of marked degree at the peak. Bunting and Thewlis believe that in the case of the neutrophil it is the reaction to living organisms and local injury produced by them, and in the case of the cells of the lymphoid group, it is the reaction to toxins. The eosinophil reactions appear to be connected with inflammations in the skin and mucous membrane, although emigrated eosinophils are constantly found in lymphoid tissue when subject to toxic injury. The monocyte reactions have not been sufficiently uniform to give evidence of a general type of reaction. These pictures are not presented as being of value in the diagnosis and differentiation of the infectious diseases, yet they have been used practically in conjunction with suggestive clinical evidence in leading to the isolation of patients before the distinctive manifestations of the particular infection have appeared.

Effect of Mercurochrome on Germicidal Properties of Blood.—Walker's experiments are said to show that mercurochrome-220 soluble in the concentration of from 1:25,600 to 1:400 has no appreciable effect on the bactericidal activity of fresh defibrinated blood toward the colon bacillus; 1:200 mercurochrome completely destroys this activity. Staphylococci and streptococci grow much more luxuriantly in blood containing from 1:25,600 to 1:400 mercurochrome than they do in fresh defibrinated blood without mercurochrome. This effect seems to be brought about by an injurious action of mercurochrome on the leukocytes and constitutes at least a theoretical objection to its use intravenously. Any beneficial results following the clinical use of mercurochrome in septicemia cannot be attributed to a specific action of mercurochrome on the causative micro-organism.

Aneurysm and Anomaly of Circle of Willis.—In a woman, aged 73, the circle of Willis was bilaterally incomplete. The right posterior communicating artery took the course normally taken by the right posterior cerebral artery. At the site of origin of the left posterior communicating artery was an aneurysm 2.5 cm. in its greatest diameter. Cerebral aneurysm associated with anomalies of the posterior communicating arteries of the circle is rare. The senile atherosclerosis present in the case reported by Jacques may have had a part in the formation of the aneurysm, rendering the involved vessel more susceptible to the mechanical factors brought about by the anomalies of the circle of Willis. The aortic and mitral valves and the myocardium were the seat of recent rheumatic changes. There was nothing to indicate that such changes occurring at an earlier period of life had a part in the formation of the aneurysm. There was no clinical or anatomic evidence of syphilis. Progressive amaurosis, more marked on the left than on the right side, was the essential manifestation of the condition.

Chronic Benzene Poisoning.—The case reported by Rohner et al. though complete in presenting all of the features so far recognized, adds nothing that is new, except possibly, the relative immunity of endothelial leukocytes in benzene (benzol, C_6H_6) poisoning and the absence of evidence of adult erythrocyte destruction. The necropsy also confirms the morbid anatomic changes described in animals. The established facts in chronic benzene poisoning are included in the following list: leukopenia, aplastic anemia, thrombocytopenia, aplasia of the bone marrow, and absence of inflammatory cell response to infection. The history of exposure to benzene in this case has been verified, thus making the chain of evidence complete.

Vacuum Tube for Mailing Blood Samples.—A vacuum tube has been devised by John for collecting, preserving and mailing blood samples. The vacuum tube contains 20 mg. of fluoride-thymol mixture (10:1), which will prevent 10 cc. of blood from clotting, and maintain the blood sugar at its original level. This makes it possible to send blood specimens to more or less distant laboratories for examination and obtain reliable results.

*Effect of Sympathetic Nervous System on Peripheral Vascular System. W. B. Mosser and K. P. A. Taylor, Philadelphia.—p. 760.

Healing of Fractures.—An experimental study was undertaken by Blaisdell and Cowan to determine the changes occurring in the different tissues of long bones following simple fracture which finally result in osseous union of the fragments. The findings are reported in detail.

Cancer of Skin.—Twenty-nine cases are reported by Morton. He is certain that a combination of surgery and radiotherapy is desirable in every case. The primary growth should be disposed of rapidly by electrocoagulation or cautery removal, thus eliminating one dangerous zone as a focus from which metastasis may occur. Squamous cell cancers of the scalp and forehead do not require removal of the regional glands; cancers of the face, cheek, eyelid, chin and nose, however, should have the glands removed also. Growths on the extremities and scrotum are prone to metastasize, and the regional glands are frequently involved. The squamous cell growths on the ear may metastasize to the parotid, preauricular or postauricular glands or to glands of the neck. Whenever possible, cooperation between surgeon and radiotherapist will offer the best chance of bettering results.

Leontiasis Ossea of Long Duration.—Hamburger and Nachlas report a case of leontiasis ossea of twenty-eight years' duration. The onset was during pregnancy. Roentgenologic study of the skull and long bones showed changes characteristic of Paget's disease.

Pathology of Joint Tuberculosis.—Of a series of twenty-three cases of joint tuberculosis seen by Smith in which it could be determined where the disease began, seventeen were primary synovial and three primary bone lesions. In three other cases the disease probably started in the bone. It is believed that the disease starts in the synovial membrane in the majority of cases in the knee and probably in other joints as well. The course of the disease was slower and more insidious in the synovial cases than in those with bone lesions. When a bone lesion was present it was easily recognizable by roentgen-ray examination. No instance was found in which the disease was confined to an epiphysis, although there were three in which it started in the metaphyses.

Effect of Sympathetic Nervous System on Peripheral Vascular System.—Mosser and Taylor summarize their results as follows: Periarterial sympathectomy in dogs and cats has uniformly failed to produce hyperthermia. Alcoholic injection of the sciatic nerve in sufficient strength to produce motor paralysis has resulted in a constant hyperthermia. The minimum concentration necessary to produce paralysis produces a maximum hyperthermia. Recovery of motor function occurs in practically all cases, even though concentrated solutions are used.

Nystagmus. E. B. Dunphy, Boston.—p. 539.

Relation of Blood Supply to Ovarian Function.—The results obtained by Macomber in his experiments are suggestive that interference with the normal nerve and blood supply, although not in any way sufficient to cause necrosis or gross pathologic changes, did interfere markedly with function. In certain cases the normal function was restored after a prolonged period; in others, immediate or eventual sterility was produced. A preliminary study of these sections shows evident histologic changes.

Fatal Asthma.—Rackemann relates the case of a woman, aged 43, with a history of hay-fever between the ages of 14 and 31, and positive skin reactions to timothy and ragweed. When the hay-fever stopped she began to have asthma, at long intervals. Two years ago, this asthma became very much aggravated and the attacks came often and were of longer duration. Finally, death occurred during a severe paroxysm. In spite of positive skin reactions, the evidence of an extrinsic cause of the asthma was not clear, since attacks had occurred at different seasons and with different surroundings. Removal to a room in the hospital relatively free from dust did not help her. The fact that the asthma occurred in well defined attacks is unexplained. Clinically, there was no cause of death other than asthma, and at necropsy, there was found only acute dilatation of the right ventricle, together with pulmonary emphysema.

Testing Vitamin Potency of Cod Liver Oil.—Holmes and Pigott suggest that for testing the vitamin content of cod liver oil it is preferable to feed the oil under consideration separate from, rather than as a constituent of, the experimental diet.

Paralysis After Antirabic Vaccine —Paralysis may follow injections of nerve substance derived from a normal animal or from an animal suffering from rabies To exclude the possibility of paralysis, either the quantity of nerve substance injected must be below a certain minimum, or else the nerve substance must previously be treated in such a way that the paralyzant is neutralized or removed and the antigenic property of the inoculum remains unaffected The toxic dose varies widely with the individual, some animals showing paralysis after less than 20 gm per kilogram of body weight, others tolerating over 1 Gm per kilogram without inconvenience The action of phenol renders the nerve substance slightly less toxic In antirabic treatment, it is desirable to be able to increase the dose of the antigen This could be done either by separating the antigen from its toxic vehicle or by neutralizing the toxicity of the vehicle The latter alternative seems the more practicable to Cornwall and Beer

Multiplication of Rabies Fixed Virus.—Cornwall and Beer assert that the rabies fixed virus does not multiply at such a rate that 0 01 Gm of brain substance can carry a lethal dose of it after two subpassages performed on the third day, but 0 01 Gm. of brain substance will always contain a lethal dose of it, if the subpassages are made on the fourth day or later.

Persistence in Body of Typhoid Bacillus.—*B. typhosus* was recovered by Cornwall and Beer from the gallbladder and from the liver tissue of an apparently healthy rabbit thirty-three months after an intravenous injection had been made.

Kala-Azar in India.—Mudalair and his associates are of the opinion that the geographic distribution of kala-azar has to be revised, since indigenous cases occur in the western half of India, which was previously supposed to be free from kala-azar.

Increasing Virulence of Germs by Culture.—Iyengar was unable to raise the virulence of *B. avisepticus* by repeated subcultures on a suitable medium. Animal passage was absolutely necessary to achieve increase in virulence. Iyengar says that what applies to "fowl cholera" may apply to other organisms as well.

Prevention of Relapses in Malaria.—The results of the treatment of about 800 cases of malignant tertian malaria contracted in northern India and observed under carefully controlled experimental conditions are reported by Sinton. He says that if this infection is treated for one week with 30 grains (2 Gm.) of quinine daily in solution, combined with alkaline treatment, at least 80 per cent, probably more, will be cured. A week's course of 30 grains daily in solution of quinine, cinchona febrifuge, or cinchona febrifuge and alkali will probably cure about 50 per cent of malignant tertian infections. Patients infected with *P. falciparum* are much more easily cured of their infections by the same doses of quinine than are those affected with *P. vivax*.

Diagnosis of Uncured Malaria.—Sinton avers that little or no advantage was gained in the diagnosis of uncured malarial infections by the use of injections of epinephrine or of strychnine.

Effects of Vasoligation.—Arland carried out the operation of vasoligation in dogs with good results. The first noticeable sign of rejuvenation was the enormous increase in appetite The most striking phenomenon was the great sexual change brought about, accompanied by an increase in the size of the penis and testes.

*Case of Multiple Myomas H S Meade —p 82

Multiple Myoma.—Meade relates the case of a man who consulted him in November, 1921, concerning a "lump" on his right thigh. It was believed to be a subcutaneous cyst, but when it was removed in March, 1922, it was found to be a solid tumor growing in the fibers of the sartorius muscle. The subsequent pathologic report stated that the tumor was a pure leiomyoma. In addition to the tumor removed for examination, this patient had one on the left side beneath the nipple, one in the axillary line, and a third in the left popliteal space. All were subcuticular, except that in the popliteal space, which was more deeply situated The tumors shelled out easily. In June, 1924, the man had a fresh appearance of myomas, not at the previous sites, but in different parts of the body, the submaxillary triangle, the neck, the left nipple, the left axillary line, and the calves of both legs The largest tumor was in the abdomen in the region of the liver. No treatment was given at this time. In July, 1925, all the growths had increased slightly in size New tumors could be felt in the right forearm, in the left arm in front, in the buttock and in the middle of the back. The general condition of the patient was not such as one would expect if the growths were malignant Meade removed all the tumors, with the exception of those in the back and liver. The microscopic diagnosis was leiomyoma with a malignant change in operation. In November, 1925, two more tumors had appeared, one in the left arm and one in the left thigh. There was a marked increase in the size of the growth in the liver.

*Two Cases of Cerebrospinal Fever. E James —p 597
*Case of Syphilis in Third Generation. W. K. Sibley —p 597.
Case of Pericardial Effusion of Tuberculous Origin J Gracie —p 598

Early Puerperal Retroversion.—Among 122 cases examined by Lack, the following abnormalities had been noted at the time of labor: 5 cases of contracted pelvis (1 treated by cesarean section, 4 by induction of premature labor) ; 1 severe accidental antepartum hemorrhage; 2 cases of placenta praevia, 1 pregnancy complicated by fibromyomas of uterus; 1 pregnancy complicated by ovarian cyst, and various other less important complications. During the puerperium, every endeavor was made to avoid the occurrence of retroversion. At the postnatal examination, the following abnormalities were noted: retroversion of the uterus, 8; subinvolution, 4, fibromyomas of uterus, 1; ovarian cyst, 1, pelvic thrombosis, 1. Retroversion of the uterus occurs during the first two weeks of the puerperium in from 5 to 10 per cent of all cases. The incidence of this condition has no relation to the parity of the patient, type of labor or abnormalities of the puerperium. The displacement can easily be corrected in most cases.

Hyperthyroidism Treated by Roentgen Rays.—Of 300 cases analyzed by Barclay and Fellows, a cure or good functional result was effected in 190 cases; seventy-five were improved; fifteen were not improved and twenty could not be traced. The cases were consecutive and unselected Eleven patients have died from intercurrent disease and three from hyperthyroidism

Diabetes as Sequel to Acute Pancreatitis.—Of several hundred cases of diabetes reviewed by Dunn et al, only two have been directly attributable to a previous acute infection of the pancreas There was reason to suspect the presence of gallstones in both these cases. The authors strongly emphasize the importance, both from the point of view of exact diagnosis and from that of treatment, of a roentgen-ray examination of the entire gastro-intestinal tract in every suspected case

Unusual Cases of Cerebrospinal Fever.—In the first case cited by James, the onset was very insidious with late meningeal involvement, though eventually, at least, the infection was of a virulent type. There was also absence of cranial nerve paralysis, with which may be correlated the postmortem findings and occurrence of hemorrhages in the heart muscle and intestine The age of the second patient, 7 weeks, was of interest

Syphilis in Third Generation.—In Sibley's case, the paternal grandfather was the originator of the disease. The parents of the patient were both very healthy. Neither parent ever revealed any signs or symptoms of the contagion

Spirochetes and Gangrene of the Lung. Bezançon.—p. 189.
*Anesthesia for Cesarean Section. A. Brindeau.—p. 194.
Maternity Hospital for Tuberculous Women. A. Couvelaire.—p. 195.
*Transfusion of Blood in the New Born. P. Guéniot.—p. 206.

Intraspinal Anesthesia for Cesarean Section.—Brindeau reiterates that intraspinal anesthesia reenforces contraction and retraction of the uterus while it paralyzes the noncontractile zone of the cervix, vulva and perineum segment. The phenomena are similar to those from severing the lumbar spinal cord in gravid animals. The intraspinal injections were used for ninety-six cesarean sections (seventy-one suprapubic). In one instance no anesthesia resulted; in eight a little ether was required in addition. In all the other cases the anesthesia was perfect, and the operation undisturbed. Intraspinal anesthesia on 232 pregnant women was followed by death of two of the women; one was apparently healthy, the other had edema and pulmonary emphysema. Complications occurred only exceptionally. From 0.08 to 0.1 Gm. of procaine, dissolved in the patient's cerebrospinal fluid, was used for the injection. Almost total absence of hemorrhage and good postoperative recovery are the advantages of the method; but the possibility of a fatal outcome should be borne in mind.

Transfusions of Blood in the New-Born.—Guéniot advocates the use of transfusions in premature and congenitally weak infants who are losing in weight, notwithstanding proper care. Twenty infants born between six and a half and eight months of pregnancy were injected intravenously with from 10 to 20 cc. of citrated blood, from two to twenty-six days after birth. In ten the transfusion was followed by gain of weight the next day; in four a few days later; in two no improvement was manifest until a second transfusion three days later. The increase of weight was progressive and rapid. In five an abnormally low temperature rose the day after the transfusion; in three the cyanosis disappeared. The results were remarkable in six premature twins, and three prematurely born of tuberculous mothers. In such cases the transfusion may prove a useful adjuvant of prophylactic BCG vaccination. The large amounts of polymorphonuclear leukocytes may reenforce the deficient secretions, and thus improve digestion and assimilation in the prematurely born. The superior longitudinal sinus seems to be the most suitable place for the transfusion; there are no mishaps if the injection is made carefully. The mother, the father or other person serving as the donor should be group tested.

Multiple Phenomena of Utero-Ovarian Derangement. Guillaume.—p. 335.

Case of Hyperostosis of One Half of the Face.—Dereux describes a case of hyperostosis of the Brissaud and Lereboullet type in a woman, aged 45. It was first noted at the age of 3 and gradually progressed with hypertrophy of the whole of the frontal bone, but it did not cause pain or discomfort. Roentgenograms showed marked asymmetry of the orbital regions and a deep bone tumor reaching the sella turcica. Of eight pregnancies only two had been carried to term; congenital syphilis may have been responsible for the hyperostosis.

Fatty Transformation of Suprarenals with Melanoderma.—Loeper and Ollivier report a case of what seemed to be fatal Addison's disease in a woman, aged 31. At necropsy both suprarenals presented primary fatty transformation, analogous to similar changes that have been observed in other glands and the thymus. It was evident that the changes were connected with congenital malformation of the suprarenals. Weakness, arterial hypotension and pronounced bronzing were the clinical features of the case. There were no signs of inflammation or tuberculosis of the suprarenals.

Paratyphoid Fever Beginning with Liver and Kidney Symptoms.—In Pagniez and Escalier's case the disease presented two distinct phases: first, jaundice, albuminuria, considerable uremia, nervous phenomena and vomiting of blood, without any fever. The second phase presented symptoms of paratyphoid B infection, confirmed by blood cultures. It is probable that both phases of the disease had been induced by the same germ. The patient recovered under vaccine treatment.

Duodenal Giardiasis. M. R. Castex and J. C. Galan.—p. 385.
Recovery in a Case of Tuberculous Meningitis. Vedel et al.—p. 388.

Familial Neurotropic Syphilis.—Marie reports two cases of general paresis, one in an adult, the other in a boy, aged 13. The father of the first patient had died from general paresis, the mother of the boy from perimeningeal encephalitis. A long list is added of authors who have recorded cases of inherited or conjugal neurotropic syphilis.

Acute Peritonitis with Cirrhosis and Ascites.—Garnier describes a case of atrophic cirrhosis of the liver with ascites in a chronic alcoholic. The disease became complicated by a fatal pneumococcus peritonitis, although the ascites had never been tapped. He has collected six similar cases published in France.

Uremic Coma Following a Diabetic Coma.—Merklen, Wolf and Bicart describe a case of diabetic coma in a young woman. Under insulin treatment the glycemia and acidosis had been reduced, and the glycosuria had disappeared. Not*withstanding this, the* patient developed an acute and fatal nephritis with oliguria, albuminuria and uremia. Evidently the renal lesions, induced by the acetonuria, are liable to *progress after the latter has subsided*. In the prognosis of diabetic coma, not only the glycemia and the acetone bodies should be considered, but also the amount of urea in the blood. The latter should be measured repeatedly, keeping in mind that diabetic coma may be succeeded by uremic coma.

Blister Fluid in Vaccination Against Measles.—Modinos applied a blistering agent to children convalescent from measles, and used the serous secretion for prophylactic vaccination during an epidemic in Alexandria. Injection of from 3 to 5 cc. of the fluid seemed to induce immunity in children exposed to contagion. He believes that it is easier to obtain 10 or 20 Gm. of serum from a blister than from puncture of a vein in children. He used preferably the blister fluid from children, as syphilis and tuberculosis are less common in them than in adults. He has never known of malarial parasites being found in blister fluid.

Journal de Radiologie et d'Electrologie, Paris

9: 561-620 (Dec.) 1925

*Radium Treatment in Cancer of the Cervix. C. Regaud et al.—p. 561.

Radium Treatment of Cancer of Uterine Cervix.—Among 403 cases treated by Regaud and his co-workers at the Paris Radium Institute, 362 were under observation for from one to six years. Disappearance of all signs of cancer was noted in an average of 26.2 per cent under the radium treatment. They conclude from their experience that surgical treatment should be applied in adeno-epithelioma of the cervix; in cancer coinciding with infection of the adnexa, and in cases rebellious to radiotherapy. Hysterectomy is preferred for malignant disease confined to the uterus, and in dubious cases. Radium alone is indicated in cancer of the cervix with the parametrium intact. Roentgen ray alone is the method of choice in inoperable cases in which the correct use of radium is not practicable, and also for recurrence after hysterectomy. Association of roentgen ray with radium is suggested if the parametrium is affected, but still accessible to radium. They make a point of sterilizing the cancer so far as possible, especially with streptococci in the cancer, before they attempt radiotherapy.

The Vascular Pedicle of the Heart. A. Cerné.—p. 1.
*Cancer of the Bladder. A. Gunsett.—p. 14.
*Radiotherapy in Cancer of the Cervix. R. Ferroux et al.—p. 21.

Cancer of the Bladder and Deep Roentgenotherapy.—Gunsett used deep roentgen rays in eleven cases of cancer of the bladder. In six the treatment was followed by complete disappearance of the tumor. Two of these patients have died since, one from cancer of the rectum, apparently independent from the tumor of the bladder; another two years later, without signs of recurrence. In four instances the treatment did not seem to influence the malignant process. In the operative cases, a partial cystectomy should be followed by roentgen-ray treatment. In inoperable cases, the roentgen rays may be used alone, or combined with radium. Parts of the tumor resistant to the roentgen ray, may be destroyed by electrocoagulation.

Treatment of Cancer of the Cervix by Radium at a Distance.—Ferroux, Monod and Regaud have been applying this method for over a year. The 4 Gm. of radium element, placed at a distance of 10 cm., was applied to the skin divided in from two to seven fields, with one or two daily exposures, for twelve or fifteen days. Thirty-two women with cancer of the cervix have been treated by this method alone, or combined with radium by the uterovaginal route. Among them were twenty-six inoperable cases. Cancerous infiltrations of the pelvis disappeared entirely, after failure of other technics. Sixteen of twenty-two patients thus treated are now on the road to recovery. The radium treatment at this distance did not induce notable local or general reactions.

*Nephrectomy and Extrarenal Tuberculosis. M. Condamin.—p. 31.
Ureterorrhaphy After Nineteen Years. Bouchard and Laquière.—p. 39.

Unilateral Nephrectomy with Extrarenal Tuberculosis.—Condamin's comparative study of 172 cases shows that the results of nephrectomy for unilateral tuberculosis depend on coexisting localizations of the infection elsewhere. With a tuberculous process restricted to one kidney, the operative mortality from nephrectomy was 2.9 per cent; the remote mortality 27.5 per cent, and 69 per cent recovered. The remote mortality from nephrectomy in patients with genital tuberculosis was 41.7 per cent, with recovery in 59 per cent; with bone and joint lesions, 62 per cent recovered. Only 29 per cent recovered of those with coexisting lesions in the lungs, and the operative mortality in this group was 9.5 per cent.

*Bacteriophage Treatment of Urinary Infections. R. Dalsace.—p. 123.
Hydremia in Postoperative Syndromes. G. Albano.—p. 144.

Bacteriophage Treatment of Urinary Infections.—Dalsace applied in infections of the urinary apparatus a bacteriophage from colon bacilli in seventeen cases, and from staphylococci in eleven. From 2 to 3 cc. of a colon bacillus or staphylococcus bacteriophage was injected subcutaneously, and the injection was repeated every second day, for two or three times—never more than four. During this period two or three doses of 10 or 20 cc. of the lytic element were given by the mouth, supplemented by two or three instillations into the bladder of from 10 to 20 cc. of the bacteriophage. Clinical recovery occurred in two cases with colon bacillus and in six with staphylococcus infection. The treatment failed in all cases in which the lysis test in vitro was negative. The local and general reactions from the injections were insignificant. Suppurative processes, hydronephrosis, and calculi are contraindications for this bacteriophage treatment. It might be combined with vaccine therapy in certain cases.

Operative Closure of Artificial Anus. E. Pollosson and H. Comte.—p. 827.

Periarterial Sympathectomy for Pains in Lumbar Region.—Bittmann remarks that these pains are the most resistant of all symptoms to yield to treatment, and that in all medicine nothing else has elicited such a variety of ideas as to pathogenesis and treatment. In 6,240 gynecologic patients in a recent two years, at Brno, lumbar pains were the predominant complaint in 2,124 cases. In nine of these he decorticated the abdominal aorta for a stretch of 8 or 12 cm., including 4 cm. on the common iliac artery. The constant success of the intervention apparently confirmed his assumption that the pains are due to a visceral neurosis, and that the celiac plexus serves as a kind of central station to relay the impulses. He aims in treatment to block these efferent impulses by the periarterial sympathectomy, supplemented by removal of the inferior mesenteric ganglion. This does not remove the primary cause, but it blocks transmission of the pain reflex, and the lumbar pains are cured. He insists that it is not a dangerous operation, and that it has always answered the purpose in cases of secondary asthenia rebellious to all conservative measures.

Pedunculated Bone Grafts.—Curtillet and Tillier describe with illustrations three typical cases of pseudarthrosis of the tibia to show the indications for and the advantages of using a pedunculated graft for a neighboring or even a distant bone. The graft may be taken from the recipient bone itself, at a higher level, cutting a slanting pedicle in the soft parts with its base on the other bone, this base being on a level with the gap to be bridged by the graft.

Fatty Transformation of Suprarenals with Melanoderma.—Loeper and Ollivier report a case of what seemed to be fatal Addison's disease in a woman, aged 31. At necropsy both suprarenals presented primary fatty transformation, analogous to similar changes that have been observed in other glands and the thymus. It was evident that the changes were connected with congenital malformation of the suprarenals. Weakness, arterial hypotension and pronounced bronzing were the clinical features of the case There were no signs of inflammation or tuberculosis of the suprarenals

Paratyphoid Fever Beginning with Liver and Kidney Symptoms.—In Pagniez and Escalier's case the disease presented two distinct phases: first, jaundice, albuminuria, considerable uremia, nervous phenomena and vomiting of blood, without any fever. The second phase presented symptoms of paratyphoid B infection, confirmed by blood cultures. It is probable that both phases of the disease had been induced by the same germ. The patient recovered under vaccine treatment.

Familial Neurotropic Syphilis.—Marie reports two cases of general paresis, one in an adult, the other in a boy, aged 13. The father of the first patient had died from general paresis, the mother of the boy from perimeningeal encephalitis. A long list is added of authors who have recorded cases of inherited or conjugal neurotropic syphilis.

Acute Peritonitis with Cirrhosis and Ascites.—Garnier describes a case of atrophic cirrhosis of the liver with ascites in a chronic alcoholic The disease became complicated by a fatal pneumococcus peritonitis, although the ascites had never been tapped He has collected six similar cases published in France.

Uremic Coma Following a Diabetic Coma.—Merklen, Wolf and Bicart describe a case of diabetic coma in a young woman. Under insulin treatment the glycemia and acidosis had been reduced, and the glycosuria had disappeared. Notwithstanding this, the patient developed an acute and fatal nephritis with oliguria, albuminuria and uremia. Evidently the renal lesions, induced by the acetonuria, are liable to progress after the latter has subsided In the prognosis of diabetic coma, not only the glycemia and the acetone bodies should be considered, but also the amount of urea in the blood. The latter should be measured repeatedly, keeping in mind that diabetic coma may be succeeded by uremic coma.

Blister Fluid in Vaccination Against Measles.—Modinos applied a blistering agent to children convalescent from measles, and used the serous secretion for prophylactic vaccination during an epidemic in Alexandria. Injection of from 3 to 5 cc. of the fluid seemed to induce immunity in children exposed to contagion. He believes that it is easier to obtain 10 or 20 Gm. of serum from a blister than from puncture of a vein in children. He used preferably the blister fluid from children, as syphilis and tuberculosis are less common in them than in adults. He has never known of malarial parasites being found in blister fluid.

Journal de Radiologie et d'Electrologie, Paris

9: 561-620 (Dec.) 1925

*Radium Treatment in Cancer of the Cervix. C. Regaud et al.—p. 561.

Radium Treatment of Cancer of Uterine Cervix.—Among 403 cases treated by Regaud and his co-workers at the Paris Radium Institute, 362 were under observation for from one to six years. Disappearance of all signs of cancer was noted in an average of 26.2 per cent under the radium treatment. They conclude from their experience that surgical treatment should be applied in adeno-epithelioma of the cervix; in cancer coinciding with infection of the adnexa, and in cases rebellious to radiotherapy. Hysterectomy is preferred for malignant disease confined to the uterus, and in dubious cases. Radium alone is indicated in cancer of the cervix with the parametrium intact. Roentgen ray alone is the method of choice in inoperable cases in which the correct use of radium is not practicable, and also for recurrence after hysterectomy. Association of roentgen ray with radium is suggested if the parametrium is affected, but still accessible to radium. They make a point of sterilizing the cancer so far as possible, especially with streptococci in the cancer, before they attempt radiotherapy.

The Vascular Pedicle of the Heart. A. Cerné.—p. 1.
*Cancer of the Bladder. A. Gunsett.—p. 14.
*Radiotherapy in Cancer of the Cervix. R. Ferroux et al.—p. 21.

Cancer of the Bladder and Deep Roentgenotherapy.—Gunsett used deep roentgen rays in eleven cases of cancer of the bladder. In six the treatment was followed by complete disappearance of the tumor. Two of these patients have died since, one from cancer of the rectum, apparently independent from the tumor of the bladder; another two years later, without signs of recurrence. In four instances the treatment did not seem to influence the malignant process. In the operative cases, a partial cystectomy should be followed by roentgen-ray treatment. In inoperable cases, the roentgen rays may be used alone, or combined with radium. Parts of the tumor resistant to the roentgen ray, may be destroyed by electrocoagulation.

Treatment of Cancer of the Cervix by Radium at a Distance.—Ferroux, Monod and Regaud have been applying this method for over a year. The 4 Gm. of radium element, placed at a distance of 10 cm., was applied to the skin divided in from two to seven fields, with one or two daily exposures, for twelve or fifteen days. Thirty-two women with cancer of the cervix have been treated by this method alone, or combined with radium by the uterovaginal route. Among them were twenty-six inoperable cases. Cancerous infiltrations of the pelvis disappeared entirely, after failure of other technics. Sixteen of twenty-two patients thus treated are now on the road to recovery. The radium treatment at this distance did not induce notable local or general reactions.

*Nephrectomy and Extrarenal Tuberculosis. M. Condamin.—p. 31.
Ureterorrhaphy After Nineteen Years. Bouchard and Laquière.—p. 39.

Unilateral Nephrectomy with Extrarenal Tuberculosis.—Condamin's comparative study of 172 cases shows that the results of nephrectomy for unilateral tuberculosis depend on coexisting localizations of the infection elsewhere. With a tuberculous process restricted to one kidney, the operative mortality from nephrectomy was 2.9 per cent; the remote mortality 27.5 per cent, and 69 per cent recovered. The remote mortality from nephrectomy in patients with genital tuberculosis was 41.7 per cent, with recovery in 59 per cent; with bone and joint lesions, 62 per cent recovered. Only 29 per cent recovered of those with coexisting lesions in the lungs, and the operative mortality in this group was 9.5 per cent.

*Bacteriophage Treatment of Urinary Infections. R. Dalsace.—p. 123.
Hydremia in Postoperative Syndromes. G. Albano.—p. 144.

Bacteriophage Treatment of Urinary Infections.—Dalsace applied in infections of the urinary apparatus a bacteriophage from colon bacilli in seventeen cases, and from staphylococci in eleven. From 2 to 3 cc. of a colon bacillus or staphylococcus bacteriophage was injected subcutaneously, and the injection was repeated every second day, for two or three times—never more than four. During this period two or three doses of 10 or 20 cc. of the lytic element were given by the mouth, supplemented by two or three instillations into the bladder of from 10 to 20 cc. of the bacteriophage. Clinical recovery occurred in two cases with colon bacillus and in six with staphylococcus infection. The treatment failed in all cases in which the lysis test in vitro was negative. The local and general reactions from the injections were insignificant. Suppurative processes, hydronephrosis, and calculi are contraindications for this bacteriophage treatment. It might be combined with vaccine therapy in certain cases.

Operative Closure of Artificial Anus. E. Pollosson and H. Comte.—p. 827.

Periarterial Sympathectomy for Pains in Lumbar Region.—Bittmann remarks that these pains are the most resistant of all symptoms to yield to treatment, and that in all medicine nothing else has elicited such a variety of ideas as to pathogenesis and treatment. In 6,240 gynecologic patients in a recent two years, at Brno, lumbar pains were the predominant complaint in 2,124 cases. In nine of these he decorticated the abdominal aorta for a stretch of 8 or 12 cm., including 4 cm. on the common iliac artery. The constant success of the intervention apparently confirmed his assumption that the pains are due to a visceral neurosis, and that the celiac plexus serves as a kind of central station to relay the impulses. He aims in treatment to block these efferent impulses by the periarterial sympathectomy, supplemented by removal of the inferior mesenteric ganglion. This does not remove the primary cause, but it blocks transmission of the pain reflex, and the lumbar pains are cured. He insists that it is not a dangerous operation, and that it has always answered the purpose in cases of secondary asthenia rebellious to all conservative measures.

Pedunculated Bone Grafts.—Curtillet and Tillier describe with illustrations three typical cases of pseudarthrosis of the tibia to show the indications for and the advantages of using a pedunculated graft for a neighboring or even a distant bone. The graft may be taken from the recipient bone itself, at a higher level, cutting a slanting pedicle in the soft parts with its base on the other bone, this base being on a level with the gap to be bridged by the graft.

*Cancer of the Vocal Cords. Guérin.—p. 311.
Foreign Bodies in Trachea and Bronchi. E. P. Granet.—p. 314.

Preventive Treatment of Myopia.—Terrien believes that instillation of a weak miotic may not only check the progress of mild near-sightedness in school children, but may even improve vision. The treatment is still more advisable, as certain forms of myopia seem to be due to glaucoma. He suggests regular instillations morning and afternoon of a 1 per three hundred solution of pilocarpine nitrate. The vasodilatation, favoring the nutrition of the eyeball, as well as the resting of the eyes under the contracted pupil, may explain the beneficial action of the treatment. The contraction of the pupil under the miotic is not accompanied by undesirable contraction of the ciliary muscle.

Galvanocautery in Treatment of Corneal Ulcers.—De Saint-Martin has used the galvanocautery in ulcerating nongonorrheal keratitis, caused mostly by the pneumococcus. The spread of the ulcer was arrested at the first application; sometimes a second was needed, rarely a third. The hypopyon rapidly subsided, disappearing in twenty-four hours. In old cases, daily applications of iodized chloroform, or injections of milk were sometimes added He emphasizes that with the galvanocautery vision may be preserved better than with the Saemisch operation

Cancer of the Vocal Cords.—In Guérin's opinion, radium or roentgen-ray treatment should always follow—not precede—an operation for cancer of the vocal cords It seems that radium may be even preferred, especially applied externally He regards Escart and Laval's radium therapy through a thyroid window as great progress

Antiserum Treatment of Poliomyelitis.—Étienne treated with serum fourteen cases of acute myelitis in adults. He used Pettit's poliomyelitis antiserum, prepared at the Pasteur Institute in Paris In one case of the fulminating form, with generalized paralysis, 80 cc of the serum was given subcutaneously. Slight movements reappeared within forty-eight hours. The patient improved by the fifth day, was able to walk by the twelfth, and recovery was soon complete. In a subacute case with bladder disturbances and paraplegia, improvement occurred by the third day; a month later the man went back to work as assistant superintendent of a large railroad station. In a case of extensive paraplegia, with bulbar phenomena, the speech improved, and the patient recovered in a few days. A patient, treated with the serum only two months after the onset of the disease, began to walk in six days. Similar results were obtained in an old case of eleven weeks' standing when treatment was begun. A dose of 300 cc. may be sometimes needed; in cases with prolonged course and successive involvement of the spinal cord, medulla and brain, a total of 2,200 cc. of the serum was required. In recent cases, 100 cc. of the antiserum is the usual dose, given partly by intraspinal injection.

Permeability of Meninges and Vessels.—Cestan, Riser and Laborde recall that although the nerve centers are laved by the cerebrospinal fluid, the latter does not penetrate into the nerve cell. Consequently, the subarachnoid route cannot be utilized for treatment of a diffuse process, such as encephalitis. Therefore injections by the vein are indicated for this. If an active drug, like the arsenicals, could be associated with neurotropic substances, passing readily through the walls of the vessels, an elective action on the nerve cell might be attained, but this has not been realized to date.

*Parasitic Origin of Cancer. R. Vinzent.—p. 284.

Recent Works on Parasitic Origin of Cancer.—Vinzent reviews recent works on cancer published in America and England. New data have been presented on transmission of malignant disease by inoculation with filtrates and production of cancer by inoculation with bacterial cultures. If these data are confirmed, cancers must be classified in two groups: the filtrable sarcoma type, and the nonfiltrable, liable to be induced by physical agents (roentgen-rays, etc.), chemical, or biologic factors, parasites or bacteria. Vinzent emphasizes that no experimental proof has been given yet whether parasites act directly by toxins, or by transporting with them an invisible virus—a virus which later lives in symbiosis with the cancer cells.

Galvanocautery in Treatment of Laryngeal Tuberculosis.—De Reynier reports, among others, three cases in which galvanocauterization was followed by excellent local results. Pronounced infiltration of the arytenoids and epiglottis, as well as extensive ulcerations of the false cords and epiglottis disappeared in two or three months, after having persisted for months and years. In a case of tuberculosis of the tongue of over four years' standing the lesions disappeared within two months In another, ulceration of the lip healed in two months after two applications. Cicatrization of the tuberculous lesions of the larynx and elbow was manifest in the third case He asserts that similar results were obtained in hundreds of cases during the last twenty years. The influence of the galvanocautery may be due partially to afflux of leukocytes and subsequent phagocytosis. Under the action of heat, the adjacent healthy cells may produce antitoxins or retain those of the blood, thus acting on the tuberculous tissues. The galvanocautery was beneficial likewise in treatment of syphilitic gumma of the larynx A syphilitic infiltration of the arytenoids subsided almost entirely at one sitting of galvanocauterization The healing of the larynx did not influence in any way the tuberculous process in the lungs.

34: 337-352 (March 17) 1926

Hemorrhagic Pachymeningitis in Infants. R. Debré and G Semelaigne. —p 337.
Germ of Multiform Erythema C Levaditi et al.—p. 340
Reorganization of the Army Medical Department T. Tuffier —p 347.

Pachymeningitis in Infants.—Debré and Semelaigne encountered within a recent year five certain and two probable cases of hemorrhagic pachymeningitis in infants; 50 per cent died in the course of the disease. Of the others, one, aged 5 months, left the hospital after two months, in excellent condition Different sequelae developed in the others after clinical recovery: squint, unilateral amaurosis or extraventricular hydrocephalus with muscular spasms. One of the infants developed a specific chorioretinitis; another had a syphilitic father. The third presented characteristic lesions with a positive Wassermann test; in a fourth case the Wassermann test was positive in both infant and mother. These findings suggest that congenital syphilis may be an important, if not the exclusive factor of hemorrhagic pachymeningitis. Specific treatment induced a manifest improvement in three of the patients. Simultaneous mercurial inunctions and bismuth injections are recommended. The symptomatic therapy consists in arresting the hemorrhage; also puncture to reduce the intracranial pressure. Treatment for congenital syphilis may modify conditions enough to ward off grave nervous disease later. In d'Espine's case, hemorrhagic pachymeningitis appeared to be responsible for Little's syndrome, occurring over three years afterward.

Streptobacillus Responsible for Multiform Erythema.—Levaditi, Nicolau and Poincloux relate that one of them developed last year an acute septicemia accompanied by erythema, sore throat and involvement of the joints. After a sudden onset, the disease developed in three attacks within twelve days. The defervescence in each attack was followed by a papulo-erythematous eruption, predominantly on the legs. The presence of two nodules on the forearm completed the picture of a combination of erythema nodosum and acute erythema multiforme. Blood cultures revealed a new germ, which they call *Streptobacillus moniliformis*. Their experiments on rabbits, guinea-pigs and other animals demonstrated the high virulence of the bacillus, its affinity for the skin and joints, and also the immunity induced by it. They describe with illustrations the technic which enabled the discovery of the bacillus.

*Paradoxical Insulin Phenomenon. W. Fornet and E. Christensen.—p. 228.
Sulphur and Iodine in Surgical Tuberculosis. G. Amsler.—p. 230.

Hemophilia.—Collaud found no correlation between the sedimentation speed and the coagulation time in two hemophiliac patients. The stability of the fibrinogen, as measured by its precipitation by electrolytes, is probably in some relation with the sedimentation speed but not with the coagulation time. Accelerated sedimentation preceded spontaneous hemorrhages.

Casein a Diuretic.—Jarotzky modifies the Karell treatment in heart disease as follows: He gives daily for three days 600-800 Gm. of cottage cheese with 100-200 Gm. of sugar and 100 Gm. of sour cream. No other fluids are allowed. He prefers this "urea treatment" in all the cases in which mercurial preparations have been hitherto used to induce diuresis (Gelpke's calomel cure, etc.).

Paradoxical Insulin Phenomenon.—Fornet and Christensen injected rabbits six times daily with 10 units of insulin for three days. They observed a transient glycosuria on the second day after discontinuing the injections. They also prepared pills *containing 3 units of insulin* with dried ox bile and licorice powder and administered six of them three times daily for three days to a healthy man and three to another. They also had glycosuria on the second day after the administration was suspended. This shows the necessity for caution in decreasing the insulin units, as well as the action of insulin by the mouth.

Quinine in Prevention of Malaria.—Because of the fact that the anopheles does not migrate, Falcioni recommends to restrict the quinine preventive treatment to the inmates of the house of the carrier of the gametes, if the farms are isolated. An energetic and universal quinine prophylaxis is necessary in communities with a high percentage of carriers of gametes, especially when the population comes into closer contact during the harvesting time.

33: *129-176 (March 1) 1926.* Medical Section

*The Reticulo-Endothelia and Poisons. F. Guccione.—p. 129.
*Spleen and Nitrogen Metabolism. S. Marino.—p. 158.

The Reticulo-Endothelial Apparatus and Poisons.—Guccione removed the spleen in dogs, rabbits and guinea-pigs and studied the action of various hemolytic poisons. The resistance varied with the species and the poison. It increased in some after splenectomy (especially in dogs) and decreased in others. Infiltrates, fatty degeneration and necrosis of the liver certainly contributed to the death of the animals.

Spleen and Nitrogen Metabolism.—Marino found an increased amount of urea and decreased amount of ammonia and amino-acids in the urine of splenectomized dogs. The intestinal utilization of proteins was lower than before.

Amebic Adnexitis.—Rudecindo de la Fuente found amebas in the stools of two patients presenting adnexitis and other symptoms, and under emetine and arsenicals a complete cure was realized. In the first case the adnexitis was acute, and *lesions in the uterine cervix deceptively simulated cancer.* The uterus was removed but no trace of malignant disease was found. If the supposed cancer had been examined for amebas, the hysterectomy might have been avoided. After treatment of the amebiasis, the sigmoiditis and perisigmoiditis rapidly subsided. In the second case, the adnexitis was of long standing and had been treated medically at different times. The adnexitis was on the left side, as in the first case, with concomitant sigmoiditis and perisigmoiditis and amebas in the mucous secretions in the cervix. Under emetine the whole pelvic clinical picture subsided without a trace.

*Relapsing Fever in Spain. A. Zamorano y Paramo.—p. 29.

Relapsing Fever Endemic in Toledo District.—Zamorano describes six typical cases out of a large number observed in which persons who had to deal with hogs or had been bitten by ticks from hogs developed fever for two, three or four days, terminating in a sweating crisis and five to eight days of apyrexia, with regular return of the attacks of fever, but thereafter the disease subsided spontaneously after a few attacks In one of the cases reported the hogs were known to be sick at the time Certain cases suggested transmission of the disease by lice from a sick subject.

Pathogenic Mechanism of Intestinal Infection Sanarelli—p. 93 C'cn.
*Calcium Chloride in Therapeutics O Piñerua—p 98

Calcium Chloride in Therapeutics.—Piñerua relates that for twelve years he has been using calcium chloride with good results In a case of acute pulmonary lesions in a man of 50 with hemoptysis and pains in the kidneys, with tubercle bacilli in sputum and urine—the whole clinical picture developing in six months after an attack of influenza—the condition improved remarkably under calcium chloride The fever disappeared in less than three weeks, and by the thirty-fourth injection the cure seemed to be complete, except that an intercurrent otitis has impaired the hearing during the year since In a case of extensive and extremely painful tuberculous peritonitis in a boy, aged 12, a daily injection of 2 Gm of calcium chloride in 10 cc of water was given by the vein to a total of forty injections, when the boy was discharged completely cured In some of the numerous cases treated with the calcium chloride there was a reaction to the first injection amounting almost to actual shock, but it was transient in all.

Electrocardiogram of the New-Born.—Doxiades obtained electrocardiograms from ten normal infants immediately after birth The P and T waves were absent during the initial apnea, and the R was inverted With the beginning of respiration, a rapidly increasing R and T wave appeared.

The Herpes Question.—Minami and Ehara found the rabbit testis better adapted for research on herpes than the cornea or the brain Positive and practically identical results were obtained with inoculation of febrile and genital herpes and of zoster. They regard these three diseases as identical. Chickenpox gave negative results.

Diagnosis of Incipient Tuberculosis.—Jessen draws attention to a delicate pink filling of the blood vessels of the edge of the eyelids (not a chronic inflammation of the meibomian glands) which he finds frequently in beginning pulmonary tuberculosis. A circumscribed redness of the cheeks—especially of one cheek—is a sympathetic reflex from the diseased lung Fatigue in school should lead to an examination for tuberculosis Palpitations may be caused by pressure from the bronchial lymph nodes on the vagus or by direct toxic action on the heart muscle. Gastric disturbances and amenorrhea may be due to pulmonary tuberculosis A short dry cough, especially with movements, with negative findings in the pharynx, may be a sign of tuberculosis. In auscultation of the voice, a change of the loud long *a* (continental *e*) into a *oo*, *o*, or *ee* indicates infiltration of the parenchyma. A temperature over 36.9 C. (98.5 F.) in the mouth, or 37.2 (99 F.) in the rectum is abnormal. The slight rises in temperature characteristic of tuberculosis occur at noon; with mixed or other infection, in the evening. The roentgen rays may furnish a good confirmation of the clinical diagnosis. Alone, they are hardly of any value in diagnosis of incipient tuberculosis, especially if the roentgenologist is not an expert.

Disappearance of Dyes from the Blood.—Wittgenstein and Krebs found a rapid disappearance from the circulation of intravenously injected basic dyes. Acid dyes remain in the blood plasma much longer, especially the colloidal ones. Water blue was found as late as two months after the injection A greater absorption by the protoplasm of the cells explains the rapid disappearance and the high toxicity (0.2-0.8 Gm per five kilograms of body weight) of the basic dyes

Amidopyrine and the Intestine.—Januschke and Lasch found a lowering of the tonus of surviving intestine in weak solutions of amidopyrine. This explains the clinical observation on the spasmolytic action of 0.05 Gm. of the substance in infants, while the peristalsis was not impaired.

Blood Groups in Hemophilia.—Kubányi found that his hemophilic patient as well as the latter's mother and sister belonged to group II (A), while his healthy brothers belonged to group III (B).

Skin Diseases.—Jadassohn observed frequently (for instance, in 75-92 per cent of cases of lichen ruber) a localization of skin diseases on the inner surface of the cheeks opposite to the teeth This region contains—unlike other mucous membranes—sebaceous glands, and is prone to pigmentation—even in the melanodermia of vagrants. It is probable that this region, as Schumacher found, developed by coalescence of the embryonic broader mouth.

Generalized Emphysema.—Reimold's patients were two children—18 months and 2 years of age—with mediastinal and subcutaneous emphysema. The prognosis in such cases is grave He made a transverse incision, 5-6 cm. long, in the jugular fossa, to allow the air to escape, and put the children for a few days into an oxygen chamber while keeping them somnolent with phenobarbital sodium. They recovered.

Cultivation of Cannabis.—Joël is opposed to the intended planting of cannabis in Germany. It is used therapeutically there only as addition to plasters for eradication of corns. The danger of its misuse is great.

Endocrine Action of Gonads.—Kylin prepared alcoholic extracts from testes and ovaries. He found that they lower the blood sugar and blood pressure in the corresponding sex.

Action of Fat and Thyroid.—Abelin observed with Miyazaki a checking of thyroid function on feeding with fat. The basal metabolic rate as well as the specific dynamic action was lower than with thyroid feeding alone, and the glycogen did not disappear from the liver.

Desiccated Milk for Children.—Czerny prefers dried milk not only to canned products but even to pasteurized milk. The dried milk should contain all the fat of the original and no additions, such as sugar.

Blocking the Nerve in Treatment of Fractures.—Müller describes the technic used at Läwen's clinic. Anesthesia of the brachial plexus in fractures or dislocations of the upper extremity, and anesthesia of the sciatic, the femoral, obturator and lateral cutaneous femoris nerves in accidents affecting the lower extremity make the reduction easy and painless. Besides this, the complete relaxation of the muscles, lasting for several hours, contributes to the restitution. Roentgen control during and after reposition is made much easier by it.

Vaccination Against Typhoid.—Spät believes that preventive vaccination against typhoid increases the predisposition for the disease in the first three months.

Dysimmunity.—Much finds that a conception of wrongly directed immunity is necessary for explanation of many immunologic phenomena. For instance, the strong reaction in tuberculosis against one partial antigen may inhibit the reaction against the lipoid, which is more important. Idiosyncrasies are another example of dysimmunity, not of a merely quantitative difference. Lymphogranulomatosis is an instance of dysimmunity of the lymph nodes; lupus, of the skin.

Inactivation of Serum.—Ohashi had almost identical results with inactivation of the serum at 60 C. for five minutes as with the usual half hour at 55 C. He has, however, the impression that the latter method strengthens the Sachs-Georgi reaction, the former the Wassermann. He prefers the former method.

Surgery in Diabetic Coma. F. Hesse.—p. 374.

Motility of Biliary Passages.—Kalk and Schoendube injected 2 cc. of pituitary extracts in twenty-two patients with catarrhal jaundice. No dark bile was obtained by the duodenal tube during the stage of increase and at the height of the jaundice. After this, the change occurred rapidly in some of the patients, slowly in others. They believe that the jaundice might have been caused by a contraction of small biliary ducts in the former group, and by disease of the liver parenchyma in the latter. They explain the absence of the reflex at the height of the disease by the assumption that the gallbladder is empty. Cholecystography seems to confirm this opinion.

Reaction to Wedlock.—Mayer surveys the changes which occur in matrimony. The women increase in weight, especially around the hips, the infantile uterus frequently grows, even without a pregnancy. The "dysmenorrhea of fiancées" disappears, and mental changes occur. He does not attempt to solve the problem of telegonia (transmission of characters of the first mate to children of the second). If proved, it would mean transmission of acquired characters.

Diphtheria with Active Immunity.—Haidvogl obtained a positive Schick test in twelve of thirty children with diphtheria. Five of them had 0.04-0.45 antitoxin units per cubic centimeter of their serum.

Tabetic Atrophy of Optic Nerve.—Behr's investigations indicate that the atrophy of the optic nerve in tabes is not a direct sequel of the action of the spirochete. The real cause is a disturbance of the nourishment of the nerve due to sclerosis of the system of glia fibers, which is caused by the spirochetes. A disturbance of the adaptation to darkness may occur earlier than any other sign. It always points to a diffuse affection of the optic nerve. Arsphenamine and bismuth are apt to aggravate the condition.

Amputation with Infected Joints.—Pekarek reports good results with Spitzy's method. In septic diseases of the joints, a rapid preliminary amputation at one level is made with knife and saw or with a specially constructed saw which cuts the soft parts as well as the bone. The septic part is removed and after revision of the bursae and other parts, the surgeon can proceed with a clean amputation.

Accretion of Plica Alaris. A. Nussbaum.—p. 540.

Intestinal Occlusion After Detachment of Gastro-Enterostomy Loop.—Chiari's patient had disturbances after gastro-enterostomy. The adhesions were therefore severed and the loop of the intestine separated from the stomach which was joined to the duodenum after resection of the pylorus. The patient returned four years later with signs of intestinal occlusion. It was due to invagination provoked by a tumor which had the characters of gastric mucosa. It had evidently developed from the part of the stomach left in the intestine after release of the gastro-enterostomy.

Periarterial Sympathectomy.—Gurewitsch believes that periarterial sympathectomy kills the blood vessel. Only its nourishment from the inside remains. Simple irritation of the adventitia has the same results as sympathectomy. He regards the latter as contraindicated, because its sequels are harmful and the benefit is slight.

Experiments on Treatment of Hernia.—Chessin concludes from his experiments that in inguinal hernia the suture of the muscle (Bassini's principle) should be abandoned.

"Transplantation of Vessels."—Weglowski claims to have obtained good results, contrary to Zabludowski's statement reported in these columns.

Blood Bilirubin in Pregnancy.—Eufinger and Bader found progressively increasing amounts of bilirubin giving the indirect reaction in the serum from 123 healthy women in the last months of pregnancy. While they never observed a direct reaction in this group, it was present in eight of twenty women with hyperemesis. The test paralleled the clinical ty of the symptoms It indicates a real injury of the —perhaps a hypertonic-spastic retention of bile in phal sense In ten cases of simple nephropathy of ancy, only the indirect reaction was obtained. The t reaction was strong in eight of fifteen eclampsia cases. of them had only slight symptoms from the kidneys. regard Hijmans van den Bergh's test in all pregnancy as just as important as the examination of the or determination of the residual nitrogen

Dienst's Pregnancy Test.—Vogel found no difference n the serum from seventy pregnant and nonpregnant when using Dienst's antithrombin pregnancy test.

inal Douches.—Schwarzkopt confirms the improvement e vaginal flora and decrease in puerperal morbidity after aily irrigation of the vagina with a 0.5 per cent solution of actic acid in the last weeks of pregnancy Alkaline irrigation mpairs the condition in about the same percentage as it improves it

Menstrual Herpes.—Blum observed a herpes of the cheek occurring regularly with the menses unless he gave the woman an injection of 0.2 Gm of sodium cacodylate on the day before the expected period

Medical Writings.—Van Rijnberk gives a case report written in careless language and the same corrected, to emphasize he importance of care in writing and the absurdity of pedantic terms especially those lugged in from other languages and mutilated in the process His aim is to insist on the use of the pure national tongue

Cyclic Forms of Psychoses.—Carp refers in particular to psychoses on a basis of schizophrenia, discussing ways and means to differentiate the true schizophrenia process from a mere reaction in a schizoid subject He stresses in particular the phenomenologic method of examination, classifying the cases according as the response to stimuli can be influenced or not, and according as the primary mental disturbance had no continuity with the patient's other life experiences The duration of the psychosis—weeks or months in the single attack—throws little if any light on the differential diagnosis. The cyclic cases have a better prognosis In Lange's hundred cases (1923), 77 per cent of the patients were nearly if not entirely free from symptoms during the long remissions.

The Vitamin C Content of Raw and Pasteurized Milk.—Van Leersum's experiments with guinea-pigs testified to the reduction of vitamin C in milk with time and lack of cooling, that the main factor in this reduction is oxidation from nixture with air The guinea-pigs fed with milk through ich air had been driven, all died from the acute scurvy nich developed Other tests confirmed this deleterious influence of air, and that the vitamin C is frequently all lost before the milk reaches the pasteurizing phase. Among the practical conclusions he presents is the necessity for filling the can or bottle of milk to the brim to leave no room for air. He adds that milk seems to have a special absorbing power for oxygen, and that the loss in vitamin C can be calculated from the oxygen content of the sample.

Vaccine Treatment of Whooping Cough.—Enklaar obtained excellent results from the vaccine in 96 per cent of the hundred children thus treated, and is puzzled at the lack of success in the remaining four cases He never saw any harm result except a slight transient infiltration in one child. The vaccine was injected intramuscularly, every second day, from one to five thousand millions of the bacteria, a total of three injections; infants bore these large doses remarkably well. The disease seemed to be conquered by the ninth or tenth day.

Effects of Milk Feeding on Rabbits.—Brouwer reports that anemia, urobilinuria and intestinal hemorrhages were observed in rabbits kept on an exclusive diet of cow's or goat's milk. There was evidently, besides the defective production of hemoglobin, exaggeration of the physiologic destruction of erythrocytes, as demonstrated by the urobilinuria, and the passage of blood through the walls of the capillaries in the intestine.

Transactions of Pediatric Congress N. Malmberg.—p. 422.

Erythema Nodosum. — Wallgren finds that erythema nodosum appears at the moment when the organism becomes allergic to tuberculosis. It represents a tuberculous eruption.

Acidosis in Treatment of Myositis.—Frolich reports the case of a boy, 2 years old, with progressive ossifying myositis. The condition was influenced remarkably well by diet tending to induce acidosis (30-40 Gm. of proteins, 30 Gm. of carbohydrates and up to 140 Gm. of fat daily). The child felt well, although he eliminated up to 0.6 Gm. of acetone daily, and his blood alkali reserve dropped to 34-36 volume per cent.

Hemolytic Jaundice.—Salomonsen found a low color index during the exacerbations of hemolytic jaundice. After the crisis, the index rose rapidly above normal.

The Heart and Cod Liver Oil.—Agduhr observed atrophy, degenerations, necrosis and hemorrhages in the organs of growing mice after addition daily of 0.1 cc. and even 0.02 Gm. of cod liver oil to their food The changes were more pronounced in animals fed on a diet poor in vitamins. The heart was one of the most seriously affected organs. Excrescences in the heart were noted in some of the animals. Edema occurred with these changes. Cats, dogs and calves are less resistant to cod liver oil than mice. He is now seeking to determine the noxious element in the oil.

Treatment with Mother's Serum.—Jundell injected from 12 to 42 cc. of the mother's serum in every alternate infant received He saw no differences in morbidity or resistance between the injected infants and the controls.

Tumors Originating in Nasal Cavities. A Saxen.—p. 1064.
Innervation of Eye Muscles in Nystagmus. O Heinonen.—p 1091.

The Blood Pressure During Excitement.—Tigerstedt compares Alvarez' findings in California students with his own experiences at Helsingfors with groups of students before and after an examination. The excitement of the impending written examination was enough to raise the blood pressure by an average of 15 mm. in the men and 19 mm. in the women, the range being from 0 to 30 mm. Other tests confirmed that even a slight emotional stress is liable to send up the blood pressure and keep it high surprisingly long. The urine gave a positive Nylander reaction at the time of the written examinations. The tests were made with a Recklinghausen cuff and mercury manometer, the subject erect, the arm hanging loose. The average just before the written test was 167 and afterward 155, with seven male students; 157 and 147 for four women students, while the average several days later was respectively, 136 and 128. The blood pressure had thus fluctuated by 38 and 34 mm. of mercury. The blood pressures on the whole averaged higher than Alvarez' figures, which Tigerstedt ascribes to a little apprehension as to the outcome of the tests He tabulates the findings in a total of forty-seven subjects.
